# Improvement of Thériault Algorithm of Index Calculus for Jacobian of Hyperelliptic Curves of Small Genus 

Koh-ichi Nagao,<br>Dept. of Engineering, Kanto-Gakuin Univ.

May 20, 2004

#### Abstract

Gaudry present a variation of index calculus attack for solving the DLP in the Jacobian of hyperelliptic curves. Harley and Thérialut improve these kind of algorithm. Here, we will present a variation of these kind of algorithm, which is faster than previous ones. Keywords Index calculus attack, Jacobian, Hyperelliptic curve, DLP,

## 1 Introduction

Gaudry [3] first present a variation of index calculus attack for hyperelliptic curves that could solve the DLP on the Jacobian of an hyperelliptic curve of small genus. Later, Harley(cf. [2]) and Thériault [1] improve this algorithm. In [1], these algorithms work in time $O\left(q^{2-\frac{2}{g+1}+\epsilon}\right)$, and $O\left(q^{2-\frac{4}{2 g+1}+\epsilon}\right)$ respectively. Thériault's algorithm uses the almost-smooth divisor $D=\sum D\left(P_{i}\right)$ that all but one of the $P_{i}$ 's are in the set $B$ called factor base. This technique was often used in the number field sieve factorization algorithm, which uses the almostsmooth integer $n=\prod p_{i}$, that all but one of the $p_{i}$ 's are in the factor base $B$, which is the set of small primes. In factorization algorithm, the cost of factorizing integer is larger than that of primary testing. So, the cost of factorizing almost-smooth integer is larger than that of normal integer of the same size, and the number that $p_{i} \notin B$ must be one. However, for the index calculus for the Jacobian of curves, we first compute the point of Jacobian and later consult whether it is almost smooth or not. So that, the new algorithm that use the 2-almost smooth divisors, that all but 2 of the $P_{i}$ 's are in the set $B$, is useful. For example, the almost smooth divisor of the form $v_{1}=\sum$ terms of $B+D\left(P_{1}\right)$, and the 2almost smooth divisors of the form $v_{2}=\sum$ terms of $B+D\left(P_{1}\right)+D\left(P_{2}\right)$,

[^0]$v_{3}=\sum$ terms of $B+D\left(P_{2}\right)+D\left(P_{3}\right)$ are given, $v_{1}-v_{2}=\sum$ terms of $B-$ $D\left(P_{2}\right), v_{1}-v_{2}+v_{3}=\sum$ terms of $B+D\left(P_{3}\right)$ are other almost smooth divisors. So, we can get much more almost smooth divisors from gathering 2 -almost smooth divisors. From this improvement, we get an attack of a running time of $O\left(q^{2-\frac{2}{g}+\epsilon}\right)$.

## 2 Jacobian arithmetic

Let $C$ be a hyperelliptic curve of genus $g$ over $\mathbb{F}_{q}$ of the form $y^{2}+$ $h(x) y=f(x)$ with $\operatorname{deg} f=2 g+1$ and $\operatorname{deg} h \leq g$.
Notation 1. Use $J_{q}$ for $\mathbf{J a c}_{C}\left(\mathbb{F}_{q}\right)$.
Further, we will assume that $\left|J_{q}\right|$ is odd prime number, for simplicity.
Definition 1. Given $D_{1}, D_{2} \in J_{q}$ such that $D_{2} \in<D_{1}>, D L P$ for $\left(D_{1}, D_{2}\right)$ on $J_{q}$ is computing $\lambda$ such that $D_{2}=\lambda D_{1}$.

For an element $P=(x, y)$ in $C\left(\overline{\mathbb{F}}_{q}\right)$, put $-P:=(x,-h(x)-y)$.
Lemma 1. $C\left(\mathbb{F}_{q}\right)$ is written by the union of disjoint sets $\mathcal{P} \cup-\mathcal{P} \cup\{\infty\}$, where $\mathcal{P}:=\{-P \mid P \in \mathcal{P}\}$.

Proof. Since $\left|J_{q}\right|$ is odd prime, we have $2 \backslash\left|J_{q}\right|$ and there are no point $P \in C\left(\mathbb{F}_{q}\right)$ such that $P=-P$.

Further, we will fix $\mathcal{P}$.
Point of $\mathbf{J a c}_{C}$ can be represented uniquely by the reduced divisor of the form

$$
\sum_{i=1}^{k} n_{i} P_{i}-\sum_{i=1}^{k} n_{i} \infty, \quad P_{i} \in C\left(\overline{\mathbb{F}}_{q}\right), \quad P_{i} \neq-P_{j} \text { for } i \neq j
$$

with $n_{i} \geq 0$ and $\sum n_{i} \leq g$.
Definition 2. The reduced divisor of a point of Jacobian $J_{q}$ is written by the elements of $C\left(\mathbb{F}_{q}\right)$ i.e.

$$
\sum_{i=1}^{k} n_{i} P_{i}-\sum_{i=1}^{k} n_{i} \infty, \quad P_{i} \in C\left(\mathbb{F}_{q}\right) .
$$

Then the point is said to be potentially smooth point.
Let $D(P):=P-\infty$. Note that $P+(-P) \sim 2 \infty$. From lemma 1, potentially smooth point $v$ of $J_{q}$ can be represented of the form

$$
\sum_{P \in \mathcal{P}} n_{P}^{(v)} D(P)
$$

with $n_{P}^{(v)} \in \mathbb{Z}$ and $\sum_{P \in \mathcal{P}}\left|n_{P}^{(v)}\right| \leq g$. Further, we will use this representation to potentially smooth points.

Definition 3. $A$ subset $B$ of $\mathcal{P}$ used to define smoothness is called factor base.
Definition 4. A point $P \in \mathcal{P} \backslash B$ is called large prime.
Definition 5. $A$ divisor $v$ of the form

$$
\sum_{P \in B} n_{P}^{(v)} D(P)
$$

is called smooth divisor.
Definition 6. $A$ divisor $v$ of the form

$$
\sum_{P \in B} n_{P}^{(v)} D(P)+n_{P^{\prime}}^{(v)} P^{\prime}
$$

where $P^{\prime}$ is a large prime, is called 1-almost smooth divisor or almost smooth divisor.
Definition 7. A divisor $v$ of the form

$$
\sum_{P \in B} n_{P}^{(v)} D(P)+n_{P^{\prime}}^{(v)} P^{\prime}+n_{P^{\prime \prime}}^{(v)} P^{\prime \prime}
$$

where $P^{\prime}, P^{\prime \prime}$ are large primes, is called 2-almost smooth divisor.
Definition 8. An element $J \in J_{q}$ is called $c$ point, if the reduced divisor representing $J$ is smooth (resp. almost smooth, resp. 2-almost smooth) divisor.

Further, we will consider the coefficients $n_{P}$ of a smooth (resp. almost smooth, resp. 2-almost smooth) divisor modulo $\left|J_{q}\right|$. For a smooth (resp. almost smooth, resp. 2-almost smooth) divisor $v$, put

$$
l(v):=\#\left\{P \in B \mid n_{P}^{(v)} \neq 0\right\}
$$

Lemma 2. Let $v_{1}, v_{2}$ be smooth (resp. almost smooth, resp. 2-almost smooth) divisors and let $r_{1}, r_{2}$ be integers modulo $\left|J_{q}\right|$. Then the cost for computing $r_{1} v_{1}+r_{2} v_{2}$ is $O\left(g^{2}(\log q)^{2}\left(l\left(v_{1}\right)+l\left(v_{2}\right)\right)\right.$.
Proof. It requires $l\left(v_{1}\right)+l\left(v_{2}\right)$-time products and additions modulo $\left|J_{q}\right|$. Note that $\left|J_{q}\right| \doteq q^{g}$. Since the cost of one elementary operation modulo $\left|J_{q}\right|$ is $\log \left|J_{q}\right|=(g \log q)^{2}$, we have this estimation.

## 3 Outline of algorithm

In this section, we present the outline of the proposed algorithm. Let $k$ be a real number satisfying $0<k<1 / 2 g$. Further in this paper, we will use $k$ as a parameter of this algorithm. Put

$$
r:=r(k)=\frac{g-1+k}{g} .
$$

We will fix a set of factor base $B$ with $|B|=q^{r}$.

## Lemma 3.

$$
2 r>1+k>1>\frac{1+r}{2}=\frac{2 g+k-1}{2 g}>\frac{(g-1)+(g+1) k}{g} .
$$

Proof. trivial.
The whole algorithm consists of the following 7 parts.
Input $C / \mathbb{F}_{q}$ hyper elliptic curve of small genus $g, D_{1}, D_{2} \in J_{q}$ such that $D_{2} \in<D_{1}>$.
Output Integer $\lambda$ modulo $\left|J_{q}\right|$ such that $D_{2}=\lambda D_{1}$.
1 Computing all points of $C\left(\mathbb{F}_{q}\right)$ and making $\mathcal{P}$ and fix $B \subset \mathcal{P}$ with $|B|=q^{r}$.
2 Gathering 2-almost smooth divisors and almost smooth divisors Computing a set $V_{2}$ of 2-almost smooth points and a set $V_{1}$ of almost smooth points of $J_{q}$, of the form $\alpha D_{1}+\beta D_{2}$ with $\left|V_{1}\right|>2 q^{\frac{(g-1)+(g+1) k}{g}}$ and $\left|V_{2}\right|>q^{1+k}$.
3 Computing a set of almost smooth divisor $H_{m}$ with $\left|H_{m}\right|>q^{(1+r) / 2}$.
4 Computing a set of smooth divisor $H$ with $|H|>q^{r}$.
5 Solving linear algebra of the size $q^{r} \times q^{r}$
Computing integers $\left\{r_{h}\right\}_{h \in H}$ modulo $\left|J_{q}\right|$, satisfying $\sum_{h \in H} r_{h} h \equiv 0 \bmod$ $\left|J_{q}\right|$.
6 Computing integers $\left\{s_{v}\right\}_{v \in V_{1} \cup V_{2}}$ modulo $\left|J_{q}\right|$, satisfying $\sum_{v \in V_{1} \cup V_{2}} s_{v} v \equiv$ $0 \bmod \left|J_{q}\right|$.
7 Computing $\lambda$.

## 4 Gathering 2-almost smooth points and almost smooth points

```
Algorithm 1 Gathering the 2-almost smooth pts and almost smooth pts
    Input: \(C / \mathbb{F}_{q}\) curve of genus \(g, D_{1}, D_{2} \in \mathbf{J a c}_{C}\left(\mathbb{F}_{q}\right)\)
    Output: \(V_{1}\) a set of almost smooth divisors, \(V_{2}\) a set of 2 -almost
        smooth divisors such that \(\left|A_{2}\right|>q^{1+k},\left|V_{1}\right|>2 q^{\frac{(g-1)+(g+1) k}{g}}\), Inte-
        gers \(\left\{\left(\alpha_{v}, \beta_{v}\right)\right\}_{v \in V_{1} \cup V_{2}}\) such that \(v=\alpha_{v} D_{1}+\beta_{v} D_{2}\)
        \(V_{1} \leftarrow\{ \}, V_{2} \leftarrow\{ \}\)
        repeat
            Let \(\alpha, \beta\) be random numbers modulo \(\left|J_{q}\right|\)
            Compute \(v=\alpha J_{1}+\beta J_{2}\)
            if \(v\) is almost smooth then
                \(V_{1} \leftarrow V_{1} \cup\{v\}\)
                \(\left(\alpha_{v}, \beta_{v}\right) \leftarrow(\alpha, \beta)\)
        end if
        if \(v\) is 2 -almost smooth then
            \(V_{2} \leftarrow V_{2} \cup\{v\}\)
            \(\left(\alpha_{v}, \beta_{v}\right) \leftarrow(\alpha, \beta)\)
        end if
    until \(\left|A_{2}\right|>q^{1+k}\) and \(\left|V_{1}\right|>2 q^{\frac{(g-1)+(g+1) k}{g}}\)
    return \(V_{1}, V_{2},\left\{\left(\alpha_{v}, \beta_{v}\right)\right\}_{v \in V_{1} \cup V_{2}}\)
```

Lemma 4. The probability that a point in $J_{q}$ is almost smooth is

$$
\frac{1}{(g-1)!} q^{(-1+r)(g-1)}
$$

and the probability that a point is 2-almost smooth is

$$
\frac{1}{2(g-2)!} q^{(-1+r)(g-2)} .
$$

Proof. We can get above lemma similarly from proposition $3,4,5$ in [1]. For example, the probability of 2 -almost smooth points is roughly estimated by

$$
\frac{(2|B|)^{g-2}(2|\mathcal{P} \backslash B|)^{2}}{2!(g-2)!} \div\left|J_{q}\right| \doteq \frac{\left(q^{r}\right)^{g-2} q^{2}}{2!(g-2)!q^{g}}=\frac{1}{2(g-2)!} q^{(-1+r)(g-2)}
$$

From this lemma, the number of the loops that $\left|V_{2}\right|>q^{1+k}$ is estimated by

$$
q^{(1+k)} \cdot 2(g-2)!q^{(1-r)(g-2)}=2(g-2)!q^{2 r}
$$

and the number of the loops that $\left|V_{1}\right|>2 q^{\frac{(g-1)+(g+1) k}{g}}$ is estimated by

$$
2 q^{\frac{(g-1)+(g+1) k}{g}} \cdot(g-1)!q^{(1-r)(g-1)}=2(g-1)!q^{2 r}
$$

Since the cost of computing Jacobian $v=\alpha D_{1}+\beta D_{2}$ is $O\left(g^{2}(\log q)^{2}\right)$ and the cost of judging whether $v$ is potentially smooth or not is $O\left(g^{2}(\log q)^{3}\right)$, the total cost of this part is estimated by

$$
O\left(g^{2}(g-1)!(\log q)^{3} q^{2 r}\right)
$$

Here, we will estimate the required storage. Note that the bit-length of one relative smooth point is $2 g \log q$. So, the storage for $V_{1}$, the set of almost smooth divisors, is $O\left(g \log q q^{\frac{(g-1)+(g+1) k}{g}}\right)$ and the storage for $V_{2}$, the set of 2-almost smooth divisors, is $O\left(g \log q q^{(1+k)}\right)$. From lemma 3, we have $g \log q q^{(1+k)} \gg g \log q q^{\frac{(g-1)+(g+1) k}{g}}$. So the total required storage can be estimated by

$$
O\left(g \log q q^{(1+k)}\right)
$$

## 5 Elimination of large prime (Flame work)

Let $E$ be a set of smooth divisors, and let $F$ be a set of 2 -almost smooth divisors or a set of smooth divisors. Note that element $e \in E$ and $f \in F$ are written by

$$
\begin{gathered}
e=\sum_{P \in B} n_{P}^{(e)} P+n_{P_{1}}^{(e)} P_{1} \\
f=\sum_{P \in B} n_{P}^{(f)} P+n_{P_{2}}^{(f)} P_{2}\left(+n_{P_{3}}^{(f)} P_{3}\right) .
\end{gathered}
$$

Put $\sup (e):=\left\{P_{1}\right\}$ and $\sup (f):=\left\{P_{2},\left(P_{3}\right)\right\}$. When $P \in \sup (e) \cap$ $\sup (f)$, put

$$
\phi(e, f, P):=n_{p}^{(f)} e-n_{p}^{(e)} f
$$

Trivially, $\phi(e, f, P)$ is almost smooth divisor, if $F$ is a set of 2-almost smooth divisors and $\phi(e, f, P)$ is smooth divisor, if $F$ is a set of almost smooth divisors and $e$ is not of the form constant times $f$.

## Definition 9.

$$
\begin{gathered}
e \circlearrowleft f:= \begin{cases}\phi(e, f, P) & \text { if } P \in \sup (a) \cap \sup (b) \text { and } e \neq \text { Const } \times f \\
\emptyset & \text { otherwise. }\end{cases} \\
E \circlearrowleft F:=\cup_{e \in E, f \in F} e \circlearrowleft f .
\end{gathered}
$$

Lemma 5. $E \subseteq F$ is a set of almost smooth (resp. smooth) divisors, if $F$ is a set of 2-almost smooth (resp. almost smooth) divisors.

Proof. Trivial!

We will estimate the size of $E \subseteq F$.
Lemma 6. The size of $E \subseteq F$ is estimated by

$$
|E \subseteq F|= \begin{cases}|E \| F| / q & \text { if } F \text { is 2-almost smooth } \\ \frac{1}{2}|E \| F| / q & \text { if } F \text { is almost smooth }\end{cases}
$$

Proof. Let $e \in E, f \in F$ be randomly chosen elements. Put $P:=$ $\sup (e)$. if $F$ is a set of 2 -almost smooth divisors (resp. almost smooth divisors), the probability that $P \in \sup (f)$ is $\frac{2}{|\mathcal{P} \backslash B|} \doteq \frac{1}{q}$ (resp. $\frac{1}{|\mathcal{P} \backslash B|} \doteq$ $\left.\frac{1}{2 q}\right)$, and the size is estimated by $\frac{1}{q} \times|E||F|\left(\operatorname{resp} \cdot \frac{1}{2 q} \times|E||F|\right)$.

In order to compute $E \subseteq F$, we use this algorithm.

```
Algorithm 2 Heartsuit operator
    Input: \(E, F\)
    Output: \(E \bigcirc F\)
        set \(\mathcal{P} \backslash B=\left\{R_{1}, R_{2}, . ., R_{|\mathcal{P} \backslash B|}\right\}\)
        for \(i=1,2, . .,|\mathcal{P} \backslash B|\) do
        \(s t[i] \leftarrow\}\)
    od
    for all \(e \in E\) do
        \(P=\sup (e)\)
        Compute \(i\) s.t. \(P=R_{i}\)
        \(s t[i] \leftarrow s t[i] \cup\{e\}\)
    od
    \(V \leftarrow\}\)
    for all \(f \in F\) do
        for all \(P \in \sup (f)\) do
            Compute \(i\) s.t. \(P=R_{i}\)
            if \(s t[i] \neq \emptyset\) then
                for all \(e \in s t[i]\) s.t. \(e \neq\) Const \(\times f\) do
                    \(V \leftarrow V \cup\{\phi(e, f, P)\}\)
                od
            end if
        od
    od
    return \(H\)
```

We will estimate the cost and the storage for computing $E \subseteq F$.
Lemma 7. Put $c_{1}:=\max \{l(e) \mid e \in E\}$ and $c_{2}:=\max \{l(f) \mid f \in F\}$. Assume that $|E| \ll q$. Then the cost of computing $E \bigcirc F$ is

$$
O\left(c_{1}(\log q)^{2}|E|\right)+O\left((\log q)^{2}|F|\right)+O\left(\left(c_{1}+c_{2}\right)(\log q)^{2}|E||F| / q\right)
$$

. and the required storage is

$$
O\left(c_{1} \log q|E|\right)+O\left(\left(c_{1}+c_{2}\right) \log q|E||F| / q\right)
$$

Proof. The required storage for $s t[i]$ is $O\left(c_{1} \log q|E|\right)$ and the required storage for $V$ is $O\left(\left(c_{1}+c_{2}\right) \log q|E||F| / q\right)$, since $|V| \doteq|E||F| / q$ and $\max \{l(v) \mid v \in V\}=c_{1}+c_{2}$ from lemma 2 .

Note that the cost of the routine "Computing index $i$ " is $\log q \log |\mathcal{P} \backslash B|=$ $O\left((\log q)^{2}\right)$. Also note that $|E \subseteq F|=O(|E||F| / q)$ and remark that the probability of $s t[i] \neq \emptyset$ is very small, since $|E| \ll q$. Thus, we see that the cost of the 1st loop is $O\left(c_{1}(\log q)^{2}|E|\right)$, the cost of the part "Computing index $i$ " of the 2nd loop is $O\left((\log q)^{2}|F|\right)$, and the cost of the part "Computing the elements of $V$ " of the 2nd loop is $O\left(\left(c_{1}+c_{2}\right)(\log q)^{2}|E \| F| / q\right)$ from lemma 2.

## 6 Computing $H_{m}$

In this section, we will construct $H_{m}$ a set of almost smooth divisors $\left|H_{m}\right|>2 q^{(1+r) / 2}$.

```
Algorithm 3 Computing \(H_{m}\)
    Input: \(V_{1}\) a set of almost smooth divisors s.t. \(\left|V_{1}\right|>2 q^{\frac{(g-1)+(g+1) k}{g}}\),
    \(V_{2}\) a set of 2-almost smooth divisors s.t. \(\left|V_{2}\right|>q^{(1+k)}\)
    Output: Integer \(m>0\) and \(H_{m}\) a set of almost smooth divisors s.t.
        \(\left|H_{m}\right|>2 q^{(1+r) / 2}\)
        \(H_{1} \leftarrow V_{1}\)
        \(i \leftarrow 1\)
        repeat
            \(i++\)
            \(H_{i} \leftarrow H_{i-1} \bigcirc V_{2}\)
        until \(\left|H_{i}\right|>2 q^{(1+r) / 2}\)
        \(m \leftarrow i\)
        return \(m, H_{m}\)
```

From lemma 6, the size of $H_{i}$ is estimated by

$$
\left|H_{i}\right|=\left|H_{1}\right| \times\left(q^{k}\right)^{i-1}=2 q^{\frac{(g-1)+(g i+1) k}{g}} .
$$

So, solving the equation $\frac{(g-1)+(g i+1) k}{g}=(1+r(k)) / 2$ for $i$, we have the following.
Lemma 8. $m$ is estimated by

$$
\frac{1-k}{2 g k}
$$

Further, we will assume $m=O\left(\frac{1}{g k}\right)$. Note that $\left\{l(v) \mid v \in \cup_{i \leq m} H_{i}\right\} \leq$ $m g$. From lemma 7, the cost for computing $H_{m}$ is

$$
\left.m \times\left(O\left((\log q)^{2} q^{(1+k)}\right)+O\left(m g(\log q)^{2} q^{(1+r) / 2}\right)\right)\right)
$$

and the required storage is

$$
O\left(m g \log q q^{(1+r) / 2}\right)
$$

## 7 Computing $H$

In this section, we compute $H$ a set of smooth divisors for $|H|>q^{r}$.

```
Algorithm 4 Computing \(H\)
    Input: \(H_{m}\) a set of almost smooth divisors s.t. \(\left|H_{m}\right|>2 q^{(1+r) / 2}\)
    Output: \(H\) a set of smooth divisors s.t. \(|H|>q^{r}\).
        1: \(H \leftarrow H_{m} \bigcirc H_{m}\)
        2: return \(H\)
```

From lemma 6, the size of $H$ is estimated by

$$
|H|=\left|H_{m}\right|^{2} / 2 q=2 q^{r} .
$$

Note that $\left\{l(v) \mid v \in \cup_{i \leq m} H\right\} \leq 2 m g$. From lemma 7, the cost for computing $H$ is

$$
O\left((\log q)^{2} q^{(1+r) / 2}\right)+O\left(m g(\log q)^{2} q^{r}\right)
$$

and the required storage is

$$
O\left(m g \log q q^{(1+r) / 2}\right)
$$

## 8 Two ways representation of $h \in H$

An element $h \in H$ is written by the form

$$
h=\sum_{P \in B} a_{P}^{(h)} D(P),
$$

since it is a smooth divisor. Moreover, form its construction, we see easily that

$$
l(h)=\#\left\{P \in B \mid a_{P}^{(h)} \neq 0\right\} \leq 2 m g .
$$

Set $B=\left\{R_{1}, R_{2}, \ldots, R_{|B|}\right\}$.

## Definition 10.

$$
\text { Put } \quad \operatorname{vec}(h):=\left(a_{R_{1}}^{(h)}, a_{R_{2}}^{(h)}, \ldots, a_{R_{|B|}}^{(h)}\right) \text {. }
$$

The computation of $h(=\operatorname{vec}(h))$ means the set of pairs $\left\{\left(a_{R_{i}}^{(h)}, R_{i}\right)\right\}$ for non-zero $a_{R_{i}}^{(h)}$. Note that the required storage for one $h$ is $O(m g \log q)$.

On the other hands, form its construction, $h$ is written by linear sum of $2 m$ elements of $V_{1} \cup V_{2}$. i.e.

$$
h=\sum_{v \in V_{1} \cup V_{2}} b_{v}^{(h)} v, \quad \#\left\{v \mid b_{v}^{(h)} \neq 0\right\}=2 m .
$$

## Definition 11.

$$
\text { Put } \quad \mathbf{v}(h):=\left\{\left(b_{v}^{(h)}, v\right) \mid b_{v}^{(h)} \neq 0\right\} \text {. }
$$

Note that the required storage for one $\mathbf{v}(h)$ is $O(m \log q)$.
Important Remark By little modifying the algorithm 3,4, we can obtain both representations of $h$ of the forms $\operatorname{vec}(h)$ and $\mathbf{v}(h)$. (The order of the cost and the order of the storage for computing $H$ is essentially the same. )

Further, we will assume that the computations of $\mathbf{v e c}(h)$ and $\mathbf{v}(h)$ are done.

## 9 Linear algebra

In this section, we will solve the linear algebra and finding a linear relation of $H$.

```
Algorithm 5 Linear algebra
    Input: \(H\) a set of smooth divisors such that \(|H|>q^{r}\)
    Output: Integers \(\left\{\gamma_{h}\right\}_{h \in H}\) modulo \(\left|J_{q}\right|\) s.t. \(\sum_{h \in H} \gamma_{h} h \equiv 0 \bmod \left|J_{q}\right|\)
        Set \(H=\left\{h_{1}, h_{2}, \ldots, h_{|H|}\right\}\)
        Set matrix \(M=\left({ }^{t} \boldsymbol{v e c}\left(h_{1}\right),{ }^{t} \boldsymbol{v e c}\left(h_{2}\right), \ldots,{ }^{t} \boldsymbol{\operatorname { v e c }}\left(h_{|H|}\right)\right)\)
        Solve linear algebra of \(M\) and compute \(\left(\gamma_{1}, \gamma_{2}, \ldots, \gamma_{|H|}\right)\) such that
        \(\sum_{i=1}^{|H|} \gamma_{i} \operatorname{vec}\left(h_{i}\right)=\overrightarrow{0}\)
        return \(\left\{\gamma_{i}\right\}\)
```

Note that the elements of matrix is integers modulo $\left|J_{q}\right| \doteq q^{g}$. So the cost of elementary operation modulo $J_{q}$ is $O\left(g^{2}(\log q)^{2}\right)$.
$M$ is a sparse matrix of the size $q^{r} \times q^{r}$. Note that the number of non-zero elements in one column is $2 m g$. So, using [4] [5], we can compute $\left\{\gamma_{i}\right\}$. Its cost is

$$
O\left(g^{2}(\log q)^{2} \cdot 2 m g \cdot q^{r} q^{r}\right)=O\left(m g^{3}(\log q)^{2} q^{2 r}\right)
$$

and the required storage is

$$
O\left(\log \left(q^{g}\right) m g \cdot q^{r}\right)=O\left(m g^{2} \log q q^{r}\right)
$$

(The required storage for sparse linear algebra is essentially the storage for non-zero data. Note that the bit length of integer modulo $\left|J_{q}\right|$ is $\log \left(q^{g}\right)$, the number of nonzero elements of one row is $m g$. )

## 10 Computing $s_{v}$

Remember that each element $h \in H$ is of the form $h=\sum_{v \in V_{1} \cup V_{2}} b_{v}^{(h)} v$. In the previous section, we found $\left\{\gamma_{h}\right\}$ such that $\sum_{h \in H} \gamma_{h} h \equiv 0 \bmod$
$\left|J_{q}\right|$. So, put

$$
s_{v}:=\sum_{h \in H} \gamma_{h} b_{v}^{(h)} \bmod \left|J_{q}\right| \quad \text { for all } v \in V_{1} \cup V_{2}
$$

and we have

$$
\sum_{v \in V_{1} \cup V_{2}} s_{v} v \equiv 0 \bmod \left|J_{q}\right| .
$$

```
Algorithm 6 Computing \(s_{v}\)
    Input: \(V_{1}, V_{2}, H,\left\{\gamma_{h}\right\}_{h \in H}\) s.t. \(\sum_{h \in H} \gamma_{h} h \equiv 0\)
    Output: \(\left\{s_{v}\right\}_{v \in V_{1} \cup V_{2}}\)
        for all \(v \in V_{1} \cup V_{2}\) do
        \(s_{v} \leftarrow 0\)
        od
        for all \(h \in H\) do
            for all \(v \in V_{1} \cup V_{2}\) s.t \(b_{v}^{(h)} \neq 0\) do
            \(s_{v} \leftarrow s_{v}+\gamma_{h} b_{v}^{(h)}\)
            od
        od
        return \(\left\{s_{v}\right\}\)
```

The cost of this part is

$$
O\left(g \log q q^{1+k}\right)+O\left(m g^{2}(\log q)^{2} q^{(1+r) / 2}\right)
$$

and the storage is

$$
O\left(g \log q q^{1+k}\right)
$$

## 11 Finding discreet log

In the previous section, we found $\left\{s_{v}\right\}$ such that $\sum s_{v} v \equiv 0 \bmod \left|J_{q}\right|$. In the part 2 of the algorithm, we have computed $\left(\alpha_{v}, \beta_{v}\right)$ such that

$$
v=\alpha_{v} D_{1}+\beta_{v} D_{2} .
$$

So, we have
$\sum_{v \in V_{1} \cup V_{2}} s_{v}\left(\alpha_{v} D_{1}+\beta_{v} D_{2}\right)=\left(\sum_{v \in V_{1} \cup V_{2}} s_{v} \alpha_{v}\right) D_{1}+\left(\sum_{v \in V_{1} \cup V_{2}} s_{v} \beta_{v}\right) D_{2} \equiv 0 . \bmod \left|J_{q}\right|$
So, $-\left(\sum_{v \in V_{1} \cup V_{2}} s_{v} \alpha_{v}\right) /\left(\sum_{v \in V_{1} \cup V_{2}} s_{v} \beta_{v}\right) \bmod \left|J_{q}\right|$ is required discreet log.

```
Algorithm 7 Computing \(\lambda\)
    Input: \(V_{1}, V_{2},\left\{\alpha_{v}, \beta_{v}\right\},\left\{s_{v}\right\}\)
    Output: Integer \(\lambda \bmod \left|J_{q}\right|\) s.t. \(D_{1}=\lambda D_{2}\)
        1: return \(-\left(\sum_{v \in V_{1} \cup V_{2}} s_{v} \alpha_{v}\right) /\left(\sum_{v \in V_{1} \cup V_{2}} s_{v} \beta_{v}\right) \bmod \left|J_{q}\right|\)
```

Note that the cost of this part is $O\left(g^{2}(\log q)^{2} q^{1+k}\right)$.

## 12 Cost estimation

In this section, we will estimate the cost and the required storage of whole algorithm under the assumption of

$$
k=\frac{1}{\log q} .
$$

First, remember that $m=O\left(\frac{1}{g k}\right)=O\left(\frac{\log q}{g}\right)$. By a direct computation, we have

$$
r=r(k)=\frac{g-1+k}{g}=1-\frac{1}{g}+\frac{1}{g \log q},
$$

and

$$
q^{2 r}=q^{2-\frac{2}{g}} \times \exp \left(\frac{2}{g}\right)=O\left(q^{2-\frac{2}{g}}\right)
$$

From our cost estimation, the cost of the routine except part 2 and part 5 is written by the form

$$
O\left(g^{a}(\log q)^{b} q^{c}\right) \quad a, b \leq 4, c \leq 1+k .
$$

On the other hands, the cost of the routine part 2 and part 5 is written by

$$
O\left(g^{2}(g-1)!(\log q)^{3} q^{2 r}\right) \text { and } O\left(m g^{3}(\log q)^{2} q^{2 r}\right)
$$

From lemma 3, we see $1+k<2 r$ and the cost of the whole parts can be estimated by

$$
O\left(g^{2}(g-1)!(\log q)^{3} q^{2 r}\right)=O\left(g^{2}(g-1)!(\log q)^{3} q^{2-\frac{2}{g}}\right)
$$

Similarly, we see that the required storage (dominant part is part 2 and part 7 , since $1+k>1>(1+r) / 2$ from lemma 3$)$ is
$O\left(g \log q q^{1+k}\right)=O\left(g \log q q^{1+k}\right)=O(g \log q q \exp (1))=O(g \log q q)$.

## 13 Conclusion

In ASIACRYPT2003, Thériault presented a variant of index calculus for the Jacobian of hyperelliptic curve of small genus, using almost smooth divisors. Here, we improve Thériault's result, using 2-almost divisors and propose an attack for DLP of the Jacobian of hyperelliptic curves of small genus, which works $O\left(q^{2-\frac{2}{g}+\epsilon}\right)$ running time.
