Logical Concepts in Cryptography

Abstract. This paper is about the exploration of logical concepts in cryptography and their linguistic abstraction and model-theoretic combination in a logical system, called CPL (for *Cryptographic Protocol Logic*). The paper focuses on two fundamental aspects of cryptography. Namely, the security of *communication* (as opposed to security of *storage*) and cryptographic *protocols* (as opposed to cryptographic *operators*). The logical concepts explored are the following. Primary concepts: the *modal* concepts of knowledge, norms, space, and time. Secondary concepts: knowledge de dicto and knowledge de re, confidentiality norms, truth-functional and relevant implication, multiple and complex truth values. The distinguishing feature of CPL is that it unifies and refines a variety of (not all!) existing approaches. This feature is the result of our *wholistic conception* of property-based (logics) and model-based (process algebra) formalisms. We illustrate the expressiveness of CPL on representative *requirements engineering* case studies.

Addendum. In the appendix, we extend CPL (qualitative time) with real time, i.e., time stamps, timed keys, and potentially drifting local clocks, to tCPL (quantitative time). Our extension is conservative and really simple; it requires only the refinement of two relational symbols (two new axioms resp. one new parameter) and of one operator (one new conjunct in its truth predicate), and the addition of two relational symbols (but no operators!). Our work thus provides further evidence for Lamport's claim that adding real time to an untimed formalism is really simple.

Keywords applied formal logic, information security, cryptographic protocols, combination of modal logics and process algebra, requirements engineering, real time

1 Introduction

The definition of a cryptographic protocol begins (and "ends" if this stage is not mastered[1]) with *requirements engineering*, i.e., the definition of the requirements

[1] consider "[...] although it is difficult to get cryptographic protocols right, what is really difficult is not the design of the protocol itself, but of the requirements. Many problems with security protocols arise, not because the protocol as designed did not satisfy its requirements, but because the requirements were not well understood in the first place." [1], and also, more generally [2]

(global properties) the protocol is supposed to meet. In particular, understanding protocol requirements is necessary for understanding protocol attacks, which can be looked at as negations of necessary conditions for the requirements to hold. Protocol definition and in particular requirements engineering are engineering tasks (the spirit of [3]). In contrast, the definition of cryptographic operators is a scientific task (the spirit of [4, 5]) requiring profound expertise from different fields of discrete mathematics. Protocol engineers do (and should) not have (to have) this expertise. For example, it is legitimate for a protocol engineer to "abstract" negligible probabilities and consider them as what they are — negligible. Ideally, engineers should only have to master a single, common, and formal language for requirements engineering that adequately abstracts "hard-core" mathematical concepts. Since logic is what all sciences have in common, it is natural to stipulate that such a lingua franca for requirements engineering cryptographic protocols be an appropriate logical language. Our task shall be to synthesise the relevant logical concepts in cryptography into a cryptographic protocol logic in the tradition of temporal[2] logic [6] (cf. [7] for an effort of similar ambition but in the tradition of dynamic[3] logic [8]). We will validate our language — at least at a first stage — on specification (stress on different requirements) rather than verification (stress on different protocols) case studies, since specification should precede verification. Nonetheless, the existence of verification examples is guaranteed by *subsumption* under CPL of other logics from authors with the opposite focus.

We briefly survey requirements engineering — the practice of the specification — of cryptographic protocols. Protocol designers commonly specify a cryptographic protocol jointly by a semi-formal description of its *behaviour* (or *local* properties) in terms of *protocol narrations*, and by an informal prescription of its intended *goals* (or *global* properties) in *natural language* [9]. Informal specifications present two major drawbacks: they do not have a well-defined, and thus a well-understood *meaning*, and, therefore, they do not allow for verification of correctness. In *formal* specifications of cryptographic protocols, local and global properties are expressed either explicitly *as such* in a logical (or *property*-based) language, or implicitly *as code*, resp. *as encodings* in a programming (or *model*-based) language (e.g., applied λ-Calculus [10]; process calculi: CSP [11], applied π-Calculus [12], Spi-Calculus [13], and [14]). Examples of such encodings are equations between protocol instantiations, and predicates defined inductively on the traces those instantiations may exhibit [15]. However, such encodings present four major drawbacks: (1) they have to be found; worse, (2) they may not even exist; (3) they are neither directly comparable with other encodings in the same or in other programming languages, nor with properties expressed explicitly in logical languages; and (4) they are not easy to understand because the intuition of the encoded property is not explicit in the encoding. On the other hand, process calculi are ideal *design formalisms*. That is, they offer — due to their minimalist, linguistic abstractions of modelling concepts (syntax) and

[2] more precisely, poly-dimensional (i.e., norms, knowledge, space, time) mono-modal
[3] more precisely, mono-dimensional (i.e., time) poly-modal (action parameters)

their mathematical, operational notion of execution (semantics) — a win-win situation between the (pedantic) rigour of machine models and the (practical) usability of programming languages.

Still, informal language and programming languages are inadequate for expressing and comparing cryptographic properties. It is our belief that only a logical language equipped with an appropriate notion of truth, i.e., a cryptographic *logic*, will produce the necessary adequacy. A number of logics have been proposed in this aim so far, ranging from *special-purpose*, cryptographic logics: the pioneering BAN-logic [16], a unification of several variants of BAN-logic [17]; over general-purpose propositional, modal, program, and first- and higher-order logics used for the special purpose of cryptographic protocol analysis: *propositional* ("logic programming") [18, 19]; *modal*: deontic [20], doxastic [21, 22], epistemic [23, 24], linear [25], temporal [26]; *program*: dynamic [27, 28, 7], Hoare-style [29]; *first-order* [30–32]; *higher-order* [33, 34]; to combinations thereof: doxastic-epistemic [35], doxastic-temporal [36], distributed temporal [37], dynamic-epistemic [38], epistemic-temporal [39] first-order-temporal [40], dynamic-epistemic-temporal [41], deontic-epistemic-temporal [42].

All these logics have elucidated important aspects of cryptographic communication and proved the relevance of logical concepts to the modelling of that communication. In particular, mere enunciation of maybe the three most fundamental cryptographic goals, namely secrecy, authenticity, and non-repudiation, reveals the paramount importance of the concept of *knowledge*, both in its propositional (so-called knowledge *de dicto*) and in its individual (so-called knowledge *de re*) manifestation. Possible[4] enunciations in natural language of these goals are the following (cf. Section 2.1 for their formalisations in CPL). Secrecy for a protocol: "Always and for all messages m, if it is forbidden that the adversary (Eve) *know* m then Eve does not *know* m." (knowledge de re in the present subjunctive and the present indicative mode respectively). Authenticity of a message m from the viewpoint of protocol participant a w.r.t. participant b: "a *knows that* once only b *knew* m." (knowledge de dicto in the present and knowledge de re in the past indicative mode). Non-repudiation of authorship of a message m' by b w.r.t. a corroborated by a proof m (m is a proof for a that b is the author of m'): "If a *knew* m then a *would know that* once only b *knew* m'." (knowledge de re in the past subjunctive and then in the past indicative mode, and knowledge de dicto in the conditional mode). However, general-purpose/standard epistemic logic is inadequate in a cryptographic setting due to weak paradoxes; for the same reason (standard) deontic logic is inadequate (cf. Section 2.3). And doxastic logic is inadequate due to its inadequacy for the above goals as these crucially rely on knowledge, i.e., necessarily true, and not possibly false, belief (no control of the epistemic error). Finally, special-purpose logics have been limited in their adequacy due to their choice of primitive concepts, e.g., belief, no negation/quantification, too specific concepts at the price of high extension costs.

[4] as a matter of fact unique definitions of these goals do not exist (yet)

Our goal is to supply a formal *synthesis* of logical concepts in a single, multi-dimensional[5] modal logic, namely CPL[6], that yields requirements that are *intuitive* but *abstract* w.r.t. particular models of cryptography. First, we believe that the formal method for any science is ultimately logic, as defined by a relation of satisfaction (*model*-theoretic approach[7], effectuated via *model checking* [46]) or a relation of deduction (*proof*-theoretic approach, effectuated via *automated theorem proving* [47]). Second, given that requirements engineering is mainly about meaning, i.e., understanding and formalising properties, we believe that a model-theoretic approach is — at least at a first stage — more suitable than a proof-theoretic approach. By 'intuitive' we mean that the conceptual dimensions of the requirement are apparent in distinctive forms in the formula that expresses the requirement — succinctly.

We argue that propositional and higher-order (at least beyond second order) logic, and set theory are unsuitable as front-end formalisms for requirements engineering purposes. Propositional logic is simply too weak as a specification language but is well-suited for fully-automated, approximative verification. Higher-order logic and set-theory may well be semantically sufficiently expressive; however, we opine that they are unsuitable for engineers in charge of capturing meaning of protocol requirements within an acceptable amount of time (i.e., financial cost per specification) and space (i.e., intelligibility of specifications). The intuitiveness of the specifications that a formalism yields are not just luxury, but the very — and difficult to distil — essence and a measure of its *pragmatics*, i.e., practical usefulness. The application domain of cryptographic protocols is conceptually very rich. A suitable requirements engineering formalism must organise and hard-wire/pre-compile this conceptual variety in its semantics and provide succinct and intuitive linguistic abstractions (syntax) for them. The resulting added value of such a formalism is empowerment of the engineer (speed-up of the mental process of formalisation), and more powerful tools (speed-up of model checking and automated theorem proving). Higher-order logic and set-theory, having been conceived as general-purpose formalisms, obviously lack this special-purpose semantics and syntax. However, they are well-suited as logical frameworks (back-ends) for such special-purpose formalisms (object logics). For example, our candidate language has a model-theoretic (i.e., relying on set theory) semantics.

CPL has a *first-order* fragment for making statements about protocol events and about the (individual) knowledge ("knows") and the structure of cryptographic messages induced by those events; and four *modal* fragments for making statements about confidentiality *norms* (cf. deontic logic [20]); propositional

[5] cf. [43] for a research monograph on multi-dimensional modal logic (an active research area), characterised in [44] as "... a branch of modal logic dealing with special relational structures in which the states, rather than being abstract entities, have some inner structure. ... Furthermore, the accessibility relations between these states are (partly) determined by this inner structure of the states."

[6] a preliminary, now outdated version of CPL appeared in the informal proceedings of [45]

[7] not to be confused with a model-*based formalism*

knowledge ("knows that"), i.e., knowledge of cryptographic states of affairs, (cf. epistemic logic [48]); execution *space* (cf. spatial logic [49]); and execution *time* (cf. temporal logic [6]). That is, CPL *unifies* first-order and four modal logics in a single, multi-dimensional logic. Further, CPL *refines* standard epistemic and deontic logic in the sense that it resolves the long-standing problem of weak-paradoxes (caused by logical omniscience and conflicting obligations, respectively) that these logics exhibit when applied in a cryptographic setting (cf. Section 2.3). Yet CPL (a property-based formalism) goes even further in its *wholistic ambition* in that it integrates the perhaps most important model-based framework, namely process algebra [50], in a novel way. First, CPL's temporal accessibility relation (the semantics of its temporal modalities) can be defined by an event-trace generating process (reduction) calculus, e.g., C^3 [51, 52] whose execution constraints are moreover checkable via CPL-satisfaction; and second, CPL's epistemic accessibility relation (the semantics of its epistemic modality "knows that") is the definitional basis for C^3's observational process equivalence, which can be used for the model-based (process-algebraic and complementary to property-based) formulation of protocol requirements.

A cryptographic protocol involves the concurrent interaction of participants that are physically separated by — and exchange messages across — an unreliable and insecure transmission medium. Expressing properties of concurrent interaction requires temporal operators [6]. The physical separation by an unreliable and insecure transmission medium in turn demands the epistemic and deontic modalities. To see why, consider that the existence of such a separating medium introduces an *uncertainty* among protocol participants about the *trustworthiness* of the execution of protocol actions (sending and receiving) and the contents of exchanged messages, both w.r.t. *actuality* (an epistemic concern) and *legitimacy* (a deontic concern). It is exactly the role of a cryptographic protocol to re-establish this trustworthiness through the judicious use of *cryptographic evidence*, i.e., essential information (e.g., ciphers, signatures and hash values) for the knowledge of other information (e.g., messages or truth of formulae), bred in a *crypto system* (e.g., a shared-key or public-key system) from *cryptographic germs* such as keys and nonces, themselves generated from *cryptographic seeds* (or seed values). However, any use of keys (as opposed to hash values and nonces) requires that the knowledge of those keys be shared a priori. This sharing of key knowledge is established by cryptographic protocols called *key-establishment* protocols (comprising *key-transport* and *key-agreement* protocols) [3, Chapter 12], which are executed before any cryptographic protocol that may then subsequently use those keys. Thus certain cryptographic protocols must be considered interrelated by a notion of *composition* in a common execution *space*; hence the need of spatial operators. Another argument for spatial operators comes from the fact that a correct protocol should conserve its inner correctness even when composed with other protocols, i.e., a (totally) correct protocol should be *stable under different execution contexts* [53, 54].

2 Logic

2.1 Syntax

The language $\mathcal{F}$ of CPL is parametric in the language $\mathcal{M}$ of its individuals, i.e., protocol messages. It is chiefly relational, and functional in exactly the language $\mathcal{M}$ of protocol messages it may be instantiated with. The temporal fragment of $\mathcal{F}$ coincides with the syntax of LTLP (linear temporal logic with past). We shall fix our mind on the following, comprehensive language $\mathcal{M}$ of individuals.

Definition 1 (Protocol messages). *Protocol messages $M \in \mathcal{M}$ have the following structure.* $M ::= n$ *(names, logical constants)* $\mid \blacksquare$ *(the abstract message)* $\mid p^+$ *(public keys)* $\mid \lceil M \rceil$ *(message hashes)* $\mid \{\!|M|\!\}_M$ *(symmetric message ciphers)* $\mid \{\!|M|\!\}^+_{p^+}$ *(asymmetric message ciphers)* $\mid \{\!|M|\!\}^-_p$ *(signed messages)* $\mid (M, M)$ *(message tuples).*

Names $n \in \boldsymbol{\mathcal{N}}$ are participant names $a, b \in \boldsymbol{\mathcal{P}}$, the (for the moment Dolev-Yao [55]) adversary's name `Eve`*, symmetric session ($\boldsymbol{\mathcal{K}}^1$) and long-term ($\boldsymbol{\mathcal{K}}^\infty$) keys $k \in \boldsymbol{\mathcal{K}}$, (asymmetric) private keys $p \in \boldsymbol{\mathcal{K}}^-$, and nonces $x \in \boldsymbol{\mathcal{X}}$ (also used as session identifiers). We assume that given a private key p, one can compute the corresponding public key p^+, as in DSA and Elgamal. Shared and private keys shall be referred to as* confidential keys $\boldsymbol{\mathcal{CK}}$*, i.e., keys that must remain secret. Symmetric keys may be* compound *for key* agreement *(as opposed to mere key* transport*). Message forms (open messages) F are messages with variables $v \in \mathcal{V}$.*

The abstract message is a computational artifice to represent the absence of *intelligibility*, just as the number zero is a computational artifice to represent the absence of *quantity*. The abstract message is very useful for doing knowledge-based calculations (cf. Definition 5), just as the number zero is very useful (to say the least) for doing number-based calculations. The focus on cryptographic protocols rather than cryptographic operators leads us (for the moment) to (1) making abstraction from the exact representation of messages, e.g., bit strings; and assuming (2.1) *perfect hashing*, i.e., collision resistance (hash functions are injective) and strong pre-image resistance (hash functions are not invertible, or given $\lceil M \rceil$, it is infeasible to compute M), and (2.2) *perfect encryption* (given $\{\!|M|\!\}_k$ but not the shared key k or given $\{\!|M|\!\}^+_{p^+}$ but not the private key p corresponding to the public key p^+, it is infeasible to compute M). We introduce a type language for messages to increase succinctness of statements about the structure of messages.

Definition 2 (Message types). *Message types τ have the following structure.*

$$\tau, \tau' ::= \emptyset \mid \sigma \mid \mathtt{H}[\tau] \mid \mathtt{SC}_M[\tau] \mid \mathtt{AC}_{p^+}[\tau] \mid \mathtt{S}_p[\tau] \mid \mathtt{T}[\tau, \tau'] \mid \tau \cup \tau' \mid \tau \cap \tau' \mid \tau \setminus \tau' \mid \mathtt{M}$$
$$\sigma, \sigma' ::= \mathtt{P} \mid \mathtt{Adv} \mid \varsigma \mid \mathtt{K}^+$$
$$\varsigma, \varsigma' ::= \mathtt{K}^1 \mid \mathtt{K}^\infty \mid \mathtt{K}^- \mid \mathtt{X}$$

Message type forms θ shall be message types with variables in key position.

Observe that (1) for each kind of message there is a corresponding type (e.g., $\mathtt{H}[\tau]$ for hashes, $\mathtt{SC}_M[\tau]$ for symmetric and $\mathtt{AC}_{p^+}[\tau]$ for asymmetric ciphers, $\mathtt{S}_p[\tau]$ for signatures, and $\mathtt{T}[\tau, \tau']$ for tuples); (2) encryption and signature types are parametric; and (3) the union, intersection, and difference of two message types is again a message type. In short, message types are structure-describing *dependent types* closed under union, intersection, and difference. ς and ς' denote types of dynamically generable names. We macro-define $\mathtt{P}_{\mathtt{Adv}} := \mathtt{P} \cup \mathtt{Adv}$, $\mathtt{K} := \mathtt{K}^{\mathtt{1}} \cup \mathtt{K}^{\infty}$, $\mathtt{CK} := \mathtt{K} \cup \mathtt{K}^{-}$, $\mathtt{K}^{*} := \mathtt{CK} \cup \mathtt{K}^{+}$, and $\mathtt{N} := \mathtt{P}_{\mathtt{Adv}} \cup \mathtt{K}^{*} \cup \mathtt{X}$.

Definition 3 (Formulae). *The set of formulae $\mathcal{F}$ contains precisely those propositions that are the closed predicates formed with the operators of Table 1. There, β denotes basic, α action, and δ data formulae; a, b, c denote participants and x, x' nonces; and k denotes a symmetric key and p a private key.*

Predicates can be transformed into propositions either via binding of free variables, i.e., universal (*generalisation*) or existential (*abstraction*) quantification, or via substitution of individuals for free variables (*individuation*). In accordance with standard logical methodology, basic predicates express *elementary facts*.

Table 1. Predicate language

$$
\begin{aligned}
\phi, \phi' ::= {} & \beta \mid \neg\phi \mid \phi \wedge \phi' \mid \forall v(\phi) \\
& \mid \mathsf{P}\phi \mid \mathsf{K}_a(\phi) \mid \phi \sqsupseteq \phi' \mid \phi \otimes \phi' \mid \phi \rhd \phi' \mid \phi \,\mathsf{S}\, \phi' \mid \ominus\phi \mid \oplus\phi \mid \phi \,\mathsf{U}\, \phi' \\
\beta, \beta' ::= {} & \alpha \mid \delta \\
\alpha, \alpha' ::= {} & a.x \circlearrowright x' \mid a.x \circlearrowright k.(b, c) \mid a.x \circlearrowright p.b \\
& \mid a.x \underset{\mathtt{E}\not\mathtt{ve}}{\overset{F}{\longrightarrow}} b \mid a.x \underset{\mathtt{Eve}}{\overset{F}{\longrightarrow}} b \mid a.x \underset{\mathtt{E}\not\mathtt{ve}}{\overset{F}{\longleftarrow}} b \mid a.x \underset{\mathtt{Eve}}{\longleftarrow} F \\
\delta, \delta' ::= {} & n : \sigma \mid a \,\mathsf{k}\, F \mid F \preccurlyeq F'
\end{aligned}
$$

Our symbols are — and their intuitive meaning is as they are — pronounced $\neg$ "not", $\wedge$ "and", $\forall v$ "for all v", P "it is permitted that", K_a "a knows that", $\sqsupseteq$ "epistemically/necessarily implies", $\otimes$ "conjunctively separates", $\rhd$ "assume—guarantee", S "since", $\ominus$ "previous", $\oplus$ "next", and U "until", $a.x \circlearrowright x'$ "a freshly generated the nonce x' in session x", $a.x \circlearrowright k.(b, c)$ "a freshly generated the symmetric key k for b and c in session x", $a.x \circlearrowright p.b$ "a freshly generated the private key p for b in session x", $a.x \underset{\mathtt{E}\not\mathtt{ve}}{\overset{F}{\longrightarrow}} b$ "a securely (i.e., in a way unobservable by the adversary) sent off F *as such* (i.e., not only as a strict sub-term of another message) to b in session x", $a.x \underset{\mathtt{Eve}}{\overset{F}{\longrightarrow}} b$ "a insecurely (i.e., in a way observable by the adversary) sent off F as such to b in session x", $a.x \underset{\mathtt{E}\not\mathtt{ve}}{\overset{F}{\longleftarrow}} b$ "a securely (i.e., not through the adversary) received F as such from b in session x", $a.x \underset{\mathtt{Eve}}{\longleftarrow} F$ "a insecurely (i.e., possibly from the adversary) received F as such in session x", : "has type", k "knows", and $\preccurlyeq$ "is a subterm of".

Our language is *1-sorted* because protocol participants are referred to by their name and names are transmittable data, i.e., messages. K expresses knowledge *de dicto* (or *propositional* knowledge). In contrast, k expresses knowledge *de re* (or *individual* knowledge). Knowledge de re conveys understanding of the purpose and possession of a certain piece of cryptographic information up to cryptographically irreducible parts. It is established based on the capability of participants to synthesise those pieces from previously analysed pieces. By 'understanding of the purpose' we mean (1) knowledge of the *structure* for compound, and (2) knowledge of the *identity* for atomic (names) information. Note that such understanding requires that there be a *minimal redundancy* in that information. The conditional $\phi \supseteq \phi'$ is epistemic or necessary in the sense that the set of evidence corroborating truth of the consequent ϕ' (e.g., the knowledge of a key) is *included* in the set of evidence corroborating truth of the antecedent ϕ (e.g., the knowledge of a plain text *derived* from that key). The epistemic conditional captures the epistemic dependence of the truth of the antecedent on the truth of the consequent. The formula $\phi \otimes \phi'$ is satisfied by a (protocol) model if and only if the model can be separated in exactly two parts such that one part satisfies ϕ (e.g., key distribution/production) and the other satisfies ϕ' (e.g., key use/consumption). The formula $\phi \rhd \phi'$ is satisfied by a model if and only if for all models that satisfy ϕ the parallel composition of both models satisfies ϕ' (cf. total/compositional correctness of a protocol, as mentioned earlier). Typing formulae $F : \theta$ have an essential and a pragmatic purpose. Typing of *atomic* data, i.e., when F designates a name n and θ an atomic type σ, is a linguistic abstraction for the above-mentioned essential modelling hypothesis of minimal redundancy. Typing of *compound* data simply increases succinctness of statements about the structure of messages. It is actually macro-definable in terms of typing of atomic data, equality (itself macro-definable), and existential quantification (cf. Appendix B).

We exemplify the expressiveness of CPL on a selection of *tentative* formalisations of fundamental cryptographic states of affairs. To the best of our knowledge, (1) no other existing crypto logic is sufficiently expressive to allow for the *definition* of the totality of these properties, and (2) the totality of these properties has never been expressed before in any other formalism. In fact, entire logics (e.g., [16], [23], [24]) have been designed to capture a single cryptographic state of affairs (e.g., authenticity, anonymity, resp. secrecy). We invite the reader to validate our formalisations on the criteria of intuitiveness and succinctness, but also to discern that the simplicity of the formalisation *results* is in sharp contradistinction to the difficulty of their formalisation *process*. However, thanks to the empowerment that CPL confers, a formalisation process involving such a large number of conceptual degrees of freedom has become *tractable* at an engineering level. Note that the formalisations employ macro-defined predicates (cf. Appendix B; the reader is urged to consult it) and that $\alpha(b)$ abbreviates disjunction of name generation, sending, and receiving performed by b.

Honesty b is *honest*, written $\mathsf{honest}(b)$, :iff b does never knowingly perform a forbidden action, written $\neg\Diamond\!\!\!\!+(\alpha(b) \wedge \mathsf{F}\alpha(b) \wedge \mathsf{K}_b(\mathsf{F}\alpha(b)))$.

Prudency b is *prudent*, written $\mathsf{prudent}(b)$, :iff b does never perform a forbidden action, written $\neg\Diamond\!\!\!\!+(\alpha(b) \wedge \mathsf{F}\alpha(b))$ or equivalently $\boxplus(\alpha(b) \rightarrow \mathsf{P}\alpha(b))$.

Trust a *trusts* b, written a trusts b, :iff a knows that b is prudent, written $\mathsf{K}_a(\mathsf{prudent}(b))$.

Reachability-based Secrecy A protocol has the secrecy property :iff the adversary (Eve) never knows any classified information, written $\boxplus\forall m(\mathsf{F}(\mathtt{Eve}\ \mathsf{k}\ m) \rightarrow \neg\,\mathtt{Eve}\ \mathsf{k}\ m)$.

Perfect Forward Secrecy "[...] compromise of long-term keys does not compromise past session keys." [3, Page 496], written $\neg\Diamond\!\!\!\!+(\exists(k : \mathtt{K}^{1})(\mathtt{Eve}\ \mathsf{k}\ k) \supseteq \exists(k : \mathtt{K}^{\infty})(\mathtt{Eve}\ \mathsf{k}\ k))$[8]

Anonymity b is anonymous to a in state of affairs $\phi(b)$:iff if a knows that some participant is involved in ϕ then a cannot identify that participant with b, written $\mathsf{K}_a(\exists(c : \mathtt{P})(\phi(c))) \rightarrow \neg\mathsf{K}_a(\phi(b))$.

Known-key attack "[...] an adversary obtains some keys used previously and then uses this information to determine new keys." [3, Page 41], written $\exists(v : \mathtt{CK})(\mathtt{Eve}\ \mathsf{k}\ v \wedge (\exists(v' : \mathtt{CK})(v' \neq v \wedge \mathtt{Eve}\ \mathsf{k}\ v') \supseteq \mathtt{Eve}\ \mathsf{k}\ v))$

Key confirmation for a **w.r.t.** b "[...] one party is assured that a second (possibly unidentified) party actually has possession of a particular secret key." [3, Page 492], written $k : \mathtt{K} \wedge \mathsf{K}_a(b\ \mathsf{k}\ k)$

Implicit key authentication for a **w.r.t.** b "[...] one party is assured that no other party aside from a specifically identified second party (and possibly additional identified trusted parties) may gain access to a particular secret key." [3, Page 492], written $k : \mathtt{K} \wedge \mathsf{K}_a(\forall(c : \mathtt{P}_{\mathtt{Adv}})(c\ \mathsf{k}\ k \rightarrow (c = a \vee c = b)))$

Authenticity of a datum A datum M is *authentic w.r.t. its origin* (say b) from the viewpoint of a :iff a can authentically attribute (i.e., in the sense of authorship) M to b, i.e., a knows that b authored M, written $\mathsf{K}_a(b\ \mathsf{a}\ M)$.

Non-repudiation of authorship M proves that b authored M' :iff assuming an arbitrary a knows M guarantees that a knows that b authored M', written $\forall(a : \mathtt{P})(a\ \mathsf{k}\ M \rhd \mathsf{K}_a(b\ \mathsf{a}\ M'))$.

Corruption of a participant a **by the adversary** $\mathtt{Eve}$ "$\mathtt{Eve}$ comes to know all what a knows in state of affairs ϕ", written $\forall m(a\ \mathsf{k}\ m \rightarrow (\mathtt{Eve}\ \mathsf{k}\ m \blacktriangleright \phi))$

Compositional protocol correctness protocol (plug-in) P in (initial) state $\mathfrak{h}$ satisfies property ϕ provided that P is used with a (parallel) protocol (environment) satisfying φ, written $(P, \mathfrak{h}) \models \varphi \rhd \phi$.

2.2 Semantics

Our definition of satisfaction is *anchored* (or *rooted*) and defined on protocol states, i.e., tuples $(P, \mathfrak{h}) \in \mathcal{P} \times \mathcal{H}$ of a protocol model P (i.e., a parallel-composable process term) and a protocol history $\mathfrak{h}$ (i.e., an event trace). For the purpose of this paper, we presuppose a notion of execution (e.g., [51]) $\longrightarrow \subseteq (\mathcal{P} \times \mathcal{H}) \times (\mathcal{P} \times \mathcal{H})$ (or relation of *temporal accessibility* in the jargon

[8] A material conditional would not do here because the antecedent and the consequent are *epistemically* — and thus not truth-functionally — *related* via key corruption, i.e., the *derivation* of a session key from a corrupted long-term key.

of modal logic) producing protocol events and chaining them up to form protocol histories. Protocol events have the following form: generation of a nonce x' in session x by a, written $\mathtt{N}(a, x, x')$; generation of a fresh symmetric key k for b and c in session x by a, written $\mathtt{N}(a, x, k, (b, c))$; generation of a fresh private key p for b in session x by a, written $\mathtt{N}(a, x, p, b)$; insecure input of M in session x by a, written $\mathtt{I}(a, x, M)$; secure input of M from b in session x by a, written $\mathtt{sI}(a, x, M, b)$; insecure output of M to b in session x by a, written $\mathtt{O}(a, x, M, b)$; and secure output of M to b in session x by a, written $\mathtt{sO}(a, x, M, b)$. By definition, an event ε is secure if and only if ε is unobservable by the adversary `Eve`. By convention, name generation is a secure event. We write $\varepsilon(a)$ for any of the above protocol events, $\varepsilon(a, n)$ for any of the above name-generation events, $\varepsilon(a, M)$ for any of the above communication events, and $\hat{\varepsilon}(a)$ for any of the above secure events. Protocol histories $\mathfrak{h} \in \mathcal{H}$ are simply finite words of protocol events ε, i.e., event traces $\mathfrak{h} \ ::= \ \epsilon \mid \mathfrak{h} \cdot \varepsilon$, where ϵ denotes the empty protocol history.

We define satisfaction in a functional style on the structure of formulae. Satisfaction employs *complex* (and thus multiple) truth values. Truth values are complex in the sense that they are tuples of a simple truth value (i.e., 'true' or 'false') and a set of those events (the evidence) that are necessary to corroborate that simple truth.

Definition 4 (Satisfaction). *Let $\models \subseteq (\mathcal{P} \times \mathcal{H}) \times \mathcal{F}$ denote satisfaction of a formula $\phi \in \mathcal{F}$ by a protocol state $\mathfrak{s} \in \mathcal{P} \times \mathcal{H}$ (the anchor/root of an implicit execution path model for ϕ):*

$$\begin{aligned} \mathfrak{s} \models \phi \ &: \textit{iff} \ \textit{there is a set of protocol events } \mathcal{E} \textit{ s.t. } \mathfrak{s} \models_{\mathcal{E}} \phi \\ \mathfrak{s} \models_{\mathcal{E}} \phi \ &: \textit{iff} \ \textit{for all } \mathfrak{p} \in \mathrm{paths}(\mathfrak{s}),\ [\![\phi]\!]^0_{\mathfrak{p}} = (\textit{true}, \mathcal{E}) \end{aligned}$$

where $\mathrm{paths}(\mathfrak{s})$ *denotes the set of paths* $\mathfrak{p}$ *achored/rooted in* $\mathfrak{s}$ *and induced by* $\longrightarrow$*, and* $[\![\cdot]\!]$ *denotes a function of truth denotation from formulae to complex truth values (cf. Table 2). There,*

- $\mathfrak{p}@i$ *denotes the state* $(P, \mathfrak{h})$ *at position* i *in path* $\mathfrak{p}$*.*
- $\dot{\mathfrak{h}}$ *denotes the set derived from protocol history* $\mathfrak{h}$*.*
- $\mathfrak{h} \vdash_a M$ *denotes the derivation of the individual knowledge* M *by participant* a *from* a*'s view on* $\mathfrak{h}$*, i.e., the extraction, analysis, and synthesis (cf. Appendix A) of the data that* a *has generated, received, or sent in* $\mathfrak{h}$*.*
- $\circ$ *denotes concatenation of protocol histories.*
- $\mathrm{E}^M_a(\mathfrak{h})$ *denotes the set of* earliest *events in* $\mathfrak{h}$ *that corroborate truth of the formula* $a \ \mathtt{k} \ M$*:*

$$\begin{aligned} \mathrm{E}^M_a(\mathfrak{h}) &:= \mathrm{E}^M_a(\mathfrak{h}, \epsilon) \\ \mathrm{E}^M_a(\mathfrak{h} \cdot \varepsilon, \mathfrak{h}') &:= \begin{cases} \mathrm{E}^M_a(\mathfrak{h}, \mathfrak{h}') & \textit{if } \mathfrak{h} \circ \mathfrak{h}' \vdash_a M, \textit{ and} \\ \mathrm{E}^M_a(\mathfrak{h}, \mathfrak{h}' \cdot \varepsilon) \cup \{\varepsilon\} & \textit{otherwise.} \end{cases} \\ \mathrm{E}^M_a(\epsilon, \mathfrak{h}') &:= \emptyset \end{aligned}$$

- $\Sigma := \exists(k : \mathtt{CK})(\mathtt{Eve}\ \mathsf{k}\ k \wedge \neg\, k\ \mathsf{ck}\ \mathtt{Eve})$ *denotes a state formula expressing the* fundamental state of violation *in a cryptographic setting, namely the one where the adversary has come to know a confidential key not of her own.*
- $\approx_a \subseteq (\mathcal{P} \times \mathcal{H}) \times (\mathcal{P} \times \mathcal{H})$ *denotes the relation of* epistemic accessibility *associated with the modality* K_a*; it is defined hereafter.*
- $(\!|\cdot|\!)^{\cdot}_a$ *denotes a unary function (inspired by [56]) of* cryptographic parsing *defined on protocol states and on logical formulae; it is defined hereafter on messages and tacitly lifted onto protocol states and logical formulae.*
- $\equiv$ *denotes a relation of* structural equivalence *defined on process terms and on event traces. On process terms, it denotes the smallest equivalence relation expressing associativity and commutativity of processes. On event traces, it denotes permutation, i.e.,* $\mathfrak{h} \equiv \mathfrak{h}'$ *:iff* $|\mathfrak{h}| = |\mathfrak{h}'|$ *and* $\dot{\mathfrak{h}} = \dot{\mathfrak{h}}'$*, where* $|\cdot|$ *denotes a length function.*

Permission is not macro-defined because we want to highlight that each new notion of fundamental state of violation will give rise to a new notion of permission. That is, we look at the state formula Σ as a parameter of the logic. The epistemic accessibility relation has, as previously mentioned, a double use; it not only serves as the definitional basis for the epistemic modality (K_a) of CPL, but also as the definitional basis for the observational process equivalence of C^3 [51]. Cryptographic parsing captures an agent's capability to understand the structure of a cryptographically obfuscated message. It allows the definition of a cryptographically meaningful notion of epistemic accessibility via the intermediate concept of structurally indistinguishable protocol histories. The idea is to parse unintelligible messages to the abstract message ■.

Definition 5 (Cryptographic parsing). *The cryptographic parsing function* $(\!|\cdot|\!)^{\mathfrak{h}}_a$ *associated with an agent* $a \in \mathcal{P}$ *and a protocol history* $\mathfrak{h} \in \mathcal{H}$ *(and complying with the assumptions of perfect cryptography) is an identity on names, the abstract message, and public keys; and otherwise acts as defined in Table 3.*

Definition 6 (Structurally indistinguishable protocol histories). *Two protocol histories* $\mathfrak{h}$ *and* $\mathfrak{h}'$ *are* structurally indistinguishable from the viewpoint of *an agent* a*, written* $\mathfrak{h} \approx_a \mathfrak{h}'$*, :iff* a *observes the same* event pattern *and the same* data patterns *in* $\mathfrak{h}$ *and* $\mathfrak{h}'$*. Formally, for all* $\mathfrak{h}, \mathfrak{h}' \in \mathcal{H}$*,* $\mathfrak{h} \approx_a \mathfrak{h}'$ *:iff* $\mathfrak{h} \approx_a^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}'$ *where,*

- *given that* a *is a legitimate participant or the adversary* $\mathtt{Eve}$*,*

1. $\dfrac{}{\epsilon \approx_a^{(\mathfrak{h},\mathfrak{h}')} \epsilon}$
2. $\dfrac{\mathfrak{h}_l \approx_a^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}{\mathfrak{h}_l \cdot \varepsilon(a,n) \approx_a^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r \cdot \varepsilon(a,n)}$
3. $\dfrac{\mathfrak{h}_l \approx_a^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}{\mathfrak{h}_l \cdot \varepsilon(a,M) \approx_a^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r \cdot \varepsilon(a,M')}\ (\!|M|\!)^{\mathfrak{h}}_a = (\!|M'|\!)^{\mathfrak{h}'}_a$

Table 3. Parsing on cryptographic messages

$$(\!|\lceil M \rceil|\!)^{\mathfrak{h}}_a := \begin{cases} \lceil (\!|M|\!)^{\mathfrak{h}}_a \rceil & \text{if } \mathfrak{h} \models a \mathsf{k} M, \text{ and} \\ \blacksquare & \text{otherwise.} \end{cases}$$

$$(\!|\{\!|M|\!\}_{M'}|\!)^{\mathfrak{h}}_a := \begin{cases} \{\!|(\!|M|\!)^{\mathfrak{h}}_a|\!\}_{(\!|M'|\!)^{\mathfrak{h}}_a} & \text{if } \mathfrak{h} \models a \mathsf{k} M', \text{ and} \\ \blacksquare & \text{otherwise.} \end{cases}$$

$$(\!|\{\!|M|\!\}^{+}_{p^+}|\!)^{\mathfrak{h}}_a := \begin{cases} \{\!|(\!|M|\!)^{\mathfrak{h}}_a|\!\}^{+}_{p^+} & \text{if } \mathfrak{h} \models a \mathsf{k} p \vee (a \mathsf{k} M \wedge a \mathsf{k} p^+), \text{ and} \\ \blacksquare & \text{otherwise.} \end{cases}$$

$$(\!|\{\!|M|\!\}^{-}_{p}|\!)^{\mathfrak{h}}_a := \begin{cases} \{\!|(\!|M|\!)^{\mathfrak{h}}_a|\!\}^{-}_{p} & \text{if } \mathfrak{h} \models a \mathsf{k} p^+, \text{ and} \\ \blacksquare & \text{otherwise.} \end{cases}$$

$$(\!|(M, M')|\!)^{\mathfrak{h}}_a := ((\!|M|\!)^{\mathfrak{h}}_a, (\!|M'|\!)^{\mathfrak{h}}_a)$$

– *given that a is a legitimate participant,*

4. $$\frac{\mathfrak{h}_l \approx_a^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}{\mathfrak{h}_l \cdot \varepsilon(b) \approx_a^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}\ a \neq b \qquad \frac{\mathfrak{h}_l \approx_a^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}{\mathfrak{h}_l \approx_a^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r \cdot \varepsilon(b)}\ a \neq b$$

– *given that a is the adversary* Eve,

5. $$\frac{\mathfrak{h}_l \approx_{\mathtt{Eve}}^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}{\mathfrak{h}_l \cdot \hat{\varepsilon}(b) \approx_{\mathtt{Eve}}^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}\ \mathtt{Eve} \neq b \qquad \frac{\mathfrak{h}_l \approx_{\mathtt{Eve}}^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}{\mathfrak{h}_l \approx_{\mathtt{Eve}}^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r \cdot \hat{\varepsilon}(b)}\ \mathtt{Eve} \neq b$$

6. $$\frac{\mathfrak{h}_l \approx_{\mathtt{Eve}}^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}{\mathfrak{h}_l \cdot \mathtt{I}(b, x, M) \approx_{\mathtt{Eve}}^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r \cdot \mathtt{I}(b, x, M')}\ (\!|M|\!)^{\mathfrak{h}}_{\mathtt{Eve}} = (\!|M'|\!)^{\mathfrak{h}'}_{\mathtt{Eve}}$$

7. $$\frac{\mathfrak{h}_l \approx_{\mathtt{Eve}}^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r}{\mathfrak{h}_l \cdot \mathtt{O}(b, x, M, c) \approx_{\mathtt{Eve}}^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r \cdot \mathtt{O}(b, x, M', c)}\ (\!|M|\!)^{\mathfrak{h}}_{\mathtt{Eve}} = (\!|M'|\!)^{\mathfrak{h}'}_{\mathtt{Eve}}$$

Note that the observations at the different (past) stages $\mathfrak{h}_l$ and $\mathfrak{h}_r$ in $\mathfrak{h}$ and $\mathfrak{h}'$ respectively must be made with the whole (present) knowledge of $\mathfrak{h}$ and $\mathfrak{h}'$ (cf. $\mathfrak{h}_l \approx^{(\mathfrak{h},\mathfrak{h}')} \mathfrak{h}_r$). Learning new keys may render intelligible past messages to an agent a in the present that were not to her before.

Remark 1. For all agents a including Eve, $\approx_a \subseteq \mathcal{H} \times \mathcal{H}$ is (1) an equivalence with an infinite index due to fresh-name generation, (2) not a right-congruence due to the possibility of learning new keys, (3) a refinement on the projection $\mathcal{H}|_a$ of $\mathcal{H}$ onto a's view [48], and (4) decidable.

We lift structural indistinguishability from protocol histories to protocol states, i.e., tuples of a protocol term and a protocol history, and finally obtain our relation of epistemic accessibility.

Definition 7 (Structurally indistinguishable protocol states). *Let* P_1 *and* P_2 *denote two cryptographic processes, i.e., models of cryptographic protocols, of some set* $\mathcal{P}$*. Then two protocol states* $(P_1, \mathfrak{h}_1)$ *and* $(P_2, \mathfrak{h}_2)$ *are* structurally indistinguishable from the viewpoint of *an agent* a*, written* $(P_1, \mathfrak{h}_1) \approx_a (P_2, \mathfrak{h}_2)$*, :iff* $\mathfrak{h}_1 \approx_a \mathfrak{h}_2$*.*

2.3 Discussion

In the terminology of relevant logics, both the spatial conditional $\rhd$ and the epistemic conditional $\supseteq$ are *relevant* (as opposed to the *truth-functional* material conditional $\rightarrow$) in the sense that information based on which the antecedent is evaluated is relevant to the information based on which the consequent is evaluated. In $\rhd$, the relevant (and *potential*) information is represented by the adjoint state $(Q, \mathfrak{h}')$. In $\supseteq$, the relevant (and *actual*) information is represented by the event subset $\mathcal{E}_{\phi'}$.

As an example, consider (for relevance, the model part only mentions a protocol history)

$$\epsilon \cdot \mathtt{I}(\mathtt{Eve}, \blacksquare, \{\!|M|\!\}_k) \models \mathtt{Eve}\ \mathsf{k}\ k \rhd \mathtt{Eve}\ \mathsf{k}\ M$$

which states *what* primary knowledge, namely k, Eve *requires to derive* the (secondary) knowledge M in the given model. In other words, if Eve *knew* k then Eve *would know* M in the given model. This is a property of Eve$'s$ cryptographic *knowledge* w.r.t. its *potentiality*. (The addition of information potentially leads to multiplication of knowledge.) In comparison, consider

$$\epsilon \cdot \mathtt{I}(\mathtt{Eve}, \blacksquare, \{\!|M|\!\}_k) \cdot \mathtt{I}(\mathtt{Eve}, \blacksquare, k) \models \mathtt{Eve}\ \mathsf{k}\ M \supseteq \mathtt{Eve}\ \mathsf{k}\ k$$

which states *how* Eve *actually derives* the secondary knowledge M from the primary knowledge in the given model. In other words, if Eve *knows* M then necessarily *because* Eve *knows* k in the given model. This is a property of Eve$'s$ cryptographic *knowledge* w.r.t. its *actuality*. In contrast, consider (the tautology)

$$\models (\mathtt{Eve}\ \mathsf{k}\ \{\!|M|\!\}_k \wedge \mathtt{Eve}\ \mathsf{k}\ k) \rightarrow \mathtt{Eve}\ \mathsf{k}\ M$$

which states a property of a cryptographic *operation*, namely encryption. We believe that $\rhd$ and $\supseteq$ are (perhaps *the*) two natural — and incidentally, relevant — notions of implication for cryptographic knowledge.

A particularly interesting use of the spatial and the epistemic conditional is the definition of a cryptographically meaningful notion of permission (cf. Table 2) and prohibition (cf. Appendix B). Our definition says that it is permitted that ϕ is true if and only if if ϕ *were* true then whenever the fundamental state of violation *would be* reached, it *would not be* due to ϕ being true. This (reductionistic) notion of permission is inspired by [57, Page 9] where a notion of prohibition is defined in the framework of dynamic logic. The authors resume their basic idea as "... some action is forbidden if doing the action leads to a state of violation." Observe that [57] construe a notion of *prohibition* based on *actions*, whereas we construe a notion of *permission* based on *propositions*. We recall that

the motivation of reductionistic approaches to (standard) deontic logic (SDL) is the existence of weak paradoxes in SDL. That is, SDL actually contains true statements that are counter to the normative intuition it was originally intended to capture.

In SDL permission, prohibition, and obligation are interdefinable, whereas in CPL only permission and prohibition are. In fact, there is no notion of obligation in CPL because (faulty) cryptographic protocols create a context with *conflicting obligations* whose treatment would require machinery from *defeasible* deontic logic [58]. Consider that it must be obligatory that (1) the fundamental state of violation be never reached during protocol execution, and (2) protocol participants always comply with protocol prescription. These two obligations are obviously conflicting in a context created by the execution of a faulty protocol, which by definition does reach the fundamental state of violation.

Our semantics for the epistemic modality reconciles the cryptographically intuitive but incomplete semantics from [59] with the complete (but less computational), renaming semantics from [60]. We achieve this by casting the cryptographic intuition from [59] in a simple (rule-based) and computational formulation of epistemic accessibility. Similarly to [59], we parse unintelligible data in an agent's *a individual* knowledge M into abstract messages $\blacksquare$. In addition, and inspired by [61, 60], we parse unintelligible data in an agent's *a propositional* knowledge $\mathsf{K}_a(\phi)$. Thanks to this additional parsing, our epistemic modality avoids weak paradoxes that, like in SDL, exist in standard epistemic logic (SEL). These paradoxes are due to epistemic necessitation, i.e., the fact that an agent a knows all logical truths such as $\exists v(\{\!|M|\!\}_k = \{\!|v|\!\}_k)$. To illustrate, consider the following simple example. Let $P \in \mathcal{P}$ and $M \in \mathcal{M}$. Then paradoxically $(P, \epsilon) \models \mathsf{K}_a(\exists v(\{\!|M|\!\}_k = \{\!|v|\!\}_k))$ "in" SEL but truthfully $(P, \epsilon) \not\models \mathsf{K}_a(\exists v(\{\!|M|\!\}_k = \{\!|v|\!\}_k))$ in CPL because $\models \neg\exists v(\blacksquare = \{\!|v|\!\}_k)$ (cf. "otherwise"-clause in the truth denotation of $\mathsf{K}_a(\phi)$ in Table 2). For further discussion see [61]. Note that our truth condition for the epistemic modality is an enhancement of the one from [61, 60] in the sense that we are able to eliminate one universal quantifier (the one over renamings) thanks to the employment of cryptographic parsing. Further note that our epistemic modality does capture knowledge, i.e., $\models \mathsf{K}_a(\phi) \rightarrow \phi$, due to the reflexivity of its associated accessibility relation.

3 Conclusion

We believe having accomplished with CPL an original synthesis of an unprecedented variety of logical concepts that are relevant to the logical modelling of cryptographic communication. In particular, we have (1) defined a cryptographically meaningful (in the sense of Dolev-Yao for the moment) epistemic modality, (2) invented a cryptographically interesting epistemic conditional, (3) pioneered the application of spatial logic to cryptographic concerns, and (4) shown that cryptographically meaningful deontic modalities are definable with a combination of epistemic and spatial conditional. At present, we are extending CPL with a notion of probabilistic polynomial-time computation in order to accommodate

CPL to modern cryptography. Further, in case first-order CPL should not suffice for some applications, it would be trivial to extend CPL to the second-order. Just allow (unquoted) message types (denoting sets of messages) as messages, and quantification may range over second-order entities (sets). Finally, a proof system for CPL is also one of our a desiderata.

Acknowledgement I would like to thank Mika Cohen for our stimulating discussions about crypto logics and his constructive criticism of this paper.

$\exists v(\phi) \;:=\; \neg\forall v(\neg\phi)$	there is v s.t. ϕ
$\forall(v : \theta)(\phi) \;:=\; \forall v(v : \theta \to \phi)$	
$\exists(v : \theta)(\phi) \;:=\; \exists v(v : \theta \wedge \phi)$	

Modal operators

$\mathsf{F}\phi \;:=\; \neg\mathsf{P}\phi$	it is forbidden that ϕ
$\phi \equiv \phi' \;:=\; (\phi \supseteq \phi') \wedge (\phi' \supseteq \phi)$	ϕ is epistemically equivalent to ϕ'
$\phi \oplus \phi' \;:=\; \neg(\neg\phi \otimes \neg\phi')$	ϕ disjunctively separates ϕ'
$\Box\phi \;:=\; \phi \oplus \bot$	everywhere ϕ
$\Diamond\phi \;:=\; \neg\Box\neg\phi$	somewhere ϕ
$\phi' \blacktriangleright \phi \;:=\; \neg(\phi' \rhd \neg\phi)$	assert ϕ' guarantee ϕ
$\boxminus\phi \;:=\; \phi\,\mathsf{S}\,\bot$	so far ϕ
$\diamondminus\phi \;:=\; \neg\boxminus\neg\phi$	once ϕ
$\mathsf{1}.\phi \;:=\; \phi \wedge \neg\ominus\diamondminus\phi$	for the first time ϕ
$\boxplus\phi \;:=\; \phi\,\mathsf{U}\,\bot$	henceforth ϕ
$\diamondplus\phi \;:=\; \neg\boxplus\neg\phi$	eventually ϕ
$\phi \leq \phi' \;:=\; (\phi \wedge \diamondplus\phi') \vee (\phi' \wedge \diamondminus\phi)$	ϕ before ϕ'
$\phi \rightsquigarrow \phi' \;:=\; (\phi \leftrightarrow \diamondplus\phi') \wedge (\phi' \leftrightarrow \diamondminus\phi)$	ϕ' is being caused by ϕ
$\phi \rightarrowtail \phi' \;:=\; \boxplus(\phi \rightsquigarrow \phi')$	ϕ causes ϕ'

Relational symbols

$F = F' \;:=\; F \preccurlyeq F' \wedge F' \preccurlyeq F$	F is equal to F'
$F \prec F' \;:=\; F = F' \wedge \neg\, F \preccurlyeq F'$	F is a strict subterm of F'
$a\;\mathsf{h}\;F \;:=\; \exists v(F \preccurlyeq v \wedge a\;\mathsf{k}\;v)$	a has/possesses F
$a\;\mathsf{tk}\;F \;:=\; a\;\mathsf{h}\;F \wedge \neg\, a\;\mathsf{k}\;F$	a tacitly knows F
$F : \emptyset \;:=\; \bot$	
$F : \mathtt{H}[\theta] \;:=\; \exists(v : \theta)(F = \lceil v \rceil)$	
$F : \mathtt{SC}_{F'}[\theta] \;:=\; \exists(v : \theta)(F = \{\!\lfloor v \rfloor\!\}_{F'})$	
$F : \mathtt{AC}_{p^+}[\theta] \;:=\; \exists(v : \theta)(F = \{\!\lfloor v \rfloor\!\}^+_{p^+})$	
$F : \mathtt{S}_p[\theta] \;:=\; \exists(v : \theta)(F = \{\!\lfloor v \rfloor\!\}^-_{p})$	
$F : \mathtt{T}[\theta, \theta'] \;:=\; \exists(v : \theta)\exists(v' : \theta')(F = (v, v'))$	
$F : \theta \cup \theta' \;:=\; F : \theta \vee F : \theta'$	
$F : \theta \cap \theta' \;:=\; F : \theta \wedge F : \theta'$	
$F : \theta \setminus \theta' \;:=\; F : \theta \wedge \neg\, F : \theta'$	
$F : \mathtt{M} \;:=\; \top$	
$F : \mathtt{SC}[\theta] \;:=\; \exists v(F : \mathtt{SC}_v[\theta])$	
$F : \mathtt{AC}[\theta] \;:=\; \exists(v : \mathtt{K}^+)(F : \mathtt{AC}_v[\theta])$	
$F : \mathtt{C}[\theta] \;:=\; F : \mathtt{SC}[\theta] \cup \mathtt{AC}[\theta]$	
$F : \mathtt{S}[\theta] \;:=\; \exists(v : \mathtt{K}^-)(F : \mathtt{S}_v[\theta])$	
$\theta \sqsubseteq \theta' \;:=\; \forall(v : \theta)(v : \theta')$	θ is a subtype of θ'

$\theta = \theta' \;:=\; \theta \sqsubseteq \theta' \wedge \theta' \sqsubseteq \theta$

$\theta \sqsubset \theta' \;:=\; \theta \sqsubseteq \theta' \wedge \theta' \neq \theta$

$F \mathfrak{k}\!\!\vdash F' \;:=\; \exists v(\{\!|v|\!\}_F \preccurlyeq F')$

$p^+ \mathfrak{k}\!\!\vdash^+ F \;:=\; \exists v(\{\!|v|\!\}^+_{p^+} \preccurlyeq F)$

$p \mathfrak{k}\!\!\vdash^- F \;:=\; \exists v(\{\!|v|\!\}^-_p \preccurlyeq F)$

$F \mathfrak{k}\!\!\vdash^* F' \;:=\; F \mathfrak{k}\!\!\vdash F' \vee F \mathfrak{k}\!\!\vdash^+ F' \vee F \mathfrak{k}\!\!\vdash^- F'$ — F is operational in F'

$F \multimap\!\!\!\!\!\!\mathfrak{z}\; F' \;:=\; \exists v \exists v'(F \preccurlyeq v \wedge \{\!|v|\!\}_{v'} \preccurlyeq F')$

$F \multimap\!\!\!\!\!\!\mathfrak{z}^+ F' \;:=\; \exists v \exists (p^+ : \mathtt{K}^+)(F \preccurlyeq v \wedge \{\!|v|\!\}^+_{p^+} \preccurlyeq F')$

$F \multimap\!\!\!\!\!\!\mathfrak{z}^- F' \;:=\; \exists v \exists (p : \mathtt{K}^-)(F \preccurlyeq v \wedge \{\!|v|\!\}^-_p \preccurlyeq F')$

$F \multimap\!\!\!\!\!\!\mathfrak{z}^* F' \;:=\; F \multimap\!\!\!\!\!\!\mathfrak{z}\; F' \vee F \multimap\!\!\!\!\!\!\mathfrak{z}^+ F' \vee F \multimap\!\!\!\!\!\!\mathfrak{z}^- F'$ — F is guarded in F'

$n \mapsto x \;:=\; \diamondsuit 1.\exists m(n \mathfrak{k}\!\!\vdash^* m \wedge \exists a \exists b(a.x \xrightarrow[\mathtt{Eve}]{m} b))$ — n is for session x

$a \;\mathsf{a}\; F \;:=\; \diamondsuit(a \;\mathsf{k}\; F \wedge \forall (b : \mathtt{P}_{\mathtt{Adv}})(b \;\mathsf{k}\; F \rightarrow b = a))$ — a authored F

$k \;\mathsf{sk}\; a \;:=\; \exists b \exists x \exists o(b.x \circlearrowright k.o \wedge a \preccurlyeq o)$ — k is a symmetric key for a

$k \;\mathsf{sk}^1\; a \;:=\; k \;\mathsf{sk}\; a \wedge k : \mathtt{K}^1$ — k is a session/short-term key for a

$k \;\mathsf{sk}^\infty\; a \;:=\; k \;\mathsf{sk}\; a \wedge k : \mathtt{K}^\infty$ — k is a long-term key for a

$n \;\mathsf{prk}\; a \;:=\; \exists b \exists x(b.x \circlearrowright n.a)$ — p is a private key for a

$n \;\mathsf{puk}\; a \;:=\; \exists v(v^+ = n \wedge v \;\mathsf{prk}\; a)$ — n is a public key for a

$n \;\mathsf{ck}\; a \;:=\; n \;\mathsf{sk}\; a \vee n \;\mathsf{prk}\; a$ — n is a confidential key for a

C Timed Cryptographic Protocol Logic

C.1 Introduction

The formal modelling, specification, and verification of *general-purpose timed* systems has received considerable attention from the formal methods community since the end of the nineteen-eighties. See [62] for a survey of timed models (automata, Petri nets), model- and property-based specification languages (process calculi, resp. logics), and verification tools; and [63] for a survey of timed property-based specification languages (logics).

However, the formal methods community has paid comparatively little, and only recent (since the end of the nineteen-nineties), attention to the timed aspects of *cryptographic* systems, e.g., cryptographic protocols, which due to their complexity deserve *special-purpose* models, and formalisms for their specification and verification.

We are aware of the following special-purpose formalisms for timed cryptographic protocols. Model-based formalisms (process calculi): [64], [65], [66] with *discrete* time; [67], [68], and our own contribution [52] with *dense* time. Property-based formalisms (logics): *interval*-based [69]; time-parametrised epistemic modalities [70] and a third-order logic [68] both *point*-based, and our hereby presented logic tCPL allowing for *both* temporal points *and* intervals.

Clearly, "[d]ense-time models are better for distributed systems with multiple clocks and timers, which can be tested, set, and reset independently." [62]. Specifically in cryptographic systems [71], "[c]locks can become unsynchronized due to sabotage on or faults in the clocks or the synchronization mechanism, such as overflows and the dependence on potentially unreliable clocks on remote sites [...]". Moreover [71], "[e]rroneous behaviors are generally expected during clock failures [...]".

Timed logics can be classified w.r.t. their *order* and the nature of their *temporal domain*. Order: propositional logic is simply too weak for specification purposes[9]; modal logics provide powerful abstractions for specification purposes, but are still not expressive enough (cf. main part of this report); higher-order logics are too expressive at the cost of axiomatic and computational incompleteness[10]; finally "[f]irst-order logics seem a good compromise between expressiveness and computability, since they are [axiomatically] complete in general." [62]. Core CPL is a poly-dimensional modal (norms, knowledge, space, *qualitative* time) first-order logic (cf. main part of this report).

Temporal domain: core CPL can be instantiated with a transitive, irreflexive, linear and bounded in the past, possibly branching (but a priori flattened) and unbounded (depending on the protocol) in the future, discrete (event-induced protocol states)[11] temporal accessibility relation [51]. tCPL can be instantiated with a temporal accessibility relation that *additionally* accounts for *quantitative* time [52]. That is, time is (1) rational-number[12] valued (yielding a dense temporal grain); (2) referenced explicitly (the truth of a timed formula does not depend on its evaluation time), but implicit-time operators are macro-definable (see below); (3) measured with potentially drifting local clocks (one per protocol participant), where the (standard Dolev-Yao) adversary's local clock has drift rate 1; (4) advanced monotonically by letting the adversary choose the amount by which she desires to increase her local clock (de facto de system clock)[13]; and (5) determinant for adversarial break of short-term keys, enabled jointly by key expiration and ciphertext-only attacks (the weakest reasonable attack).

The following section describes the extension of CPL to tCPL. The extension depends on the core described in the main part of this report (the reader is urged to consult it) and parallels the extension from C^3 [51] to tC^3 [52].

[9] but is good for fully-automated, approximative verification

[10] but are good as logical frameworks

[11] carrying the current process term and the history of past protocol events: "[...] neither pure state-based nor pure event-based languages quite support the natural expressiveness desirable for the specification of real-world systems [...]" [62]

[12] consider that protocol messages have finite length, which implies that real numbers (e.g., time stamps) are not transmittable as such, and that real clocks only have finite precision

[13] this amounts to a natural generalisation of the adversary's scheduling power from the control of the (relative) temporal *order* of protocol events in the network (space) to the control of their (absolute) temporal *issuing* (time)

C.2 Extension

tCPL is an Occham's-razor extension of core CPL. We subscribe to Lamport's claim that adding real-time to an untimed formalism is really simple [72]. The special-purpose machinery for timed (including cryptographic) settings need not be built from scratch nor be heavy-weight.

The temporal accessibility relation from [52] generates events $\mathtt{S}(a, x, t)$ for the setting of a's local clock to clock value t by a in session x. By convention, these events are unobservable by the adversary, i.e., they are secure.

1. addition of two new relational symbols $\leq$ and @ forming atomic formulae $E \leq E'$ and $E@a$ for the comparison of temporal expressions $E ::= t \mid E + E \mid E - E$ where $t \in \mathcal{TV} := \mathbb{Q} \cup \{\infty, -\infty\}$ (time values with the associated sort `TV` and transmittable as messages); and the testing of participant a's local clock with time E, respectively. Their truth denotation is as follows:

$$[\![E \leq E']\!]^i_{\mathfrak{p}} := ([\![E]\!] \text{ is smaller than or equal to } [\![E']\!], \emptyset)$$

where $[\![\cdot]\!]$ denotes the obvious evaluation function from temporal expressions to time values (not to be confused with the function of truth denotation $[\![\cdot]\!]^i_{\mathfrak{p}}$); and

$$[\![E@a]\!]^i_{\mathfrak{p}} := ([\![E]\!] = t + \delta_a \cdot \Delta, \{\mathtt{S}(a, x, t), \mathtt{S}(\mathtt{Eve}, \blacksquare, t_i)\})$$

where
   - t denotes the time value of a's last clock-set event in $\mathfrak{h}$, i.e., there are $\mathfrak{h}_1, \mathfrak{h}_2$, x s.t. $\mathfrak{h} = \mathfrak{h}_1 \cdot \mathtt{S}(a, x, t) \circ \mathfrak{h}_2$ and there is no x', t' s.t. $\mathtt{S}(a, x', t') \in \dot{\mathfrak{h}}_2$
   - $\delta_a \in \mathcal{TV}$ denotes the drift rate of a's local clock
   - Δ denotes the temporal difference between Eve's last clock-set event before $\mathtt{S}(a, x, t)$ and Eve's last clock-set event so far in $\mathfrak{h}$, i.e., $\Delta = \begin{cases} t_2 - t_1 & \text{if for } i \in \{1, 2\} \text{ there are } \mathfrak{h}_{i'}, \mathfrak{h}''_i,\ t_i \text{ s.t.} \\ & \quad \mathfrak{h}_i = \mathfrak{h}'_i \cdot \mathtt{S}(\mathtt{Eve}, \blacksquare, t_i) \circ \mathfrak{h}''_i \text{ and there is no } t'_i \text{ s.t.} \\ & \quad \mathtt{S}(\mathtt{Eve}, \blacksquare, t'_i) \in \dot{\mathfrak{h}}''_i, \text{ and} \\ 0 & \text{otherwise.} \end{cases}$

2. refinement (i.e., one new parameter) of the relational symbol for new-name generation $\circlearrowleft$ with a *validity tag* V of the form (t_b, t_e) for the declaration of the intended beginning ($t_b \in \mathcal{TV}$) and end ($t_e \in \mathcal{TV}$) of validity of the generated name (typically a key). Its truth denotation is the following:

$$[\![a.x \circlearrowleft n.(\boxed{V}, O)]\!]^i_{\mathfrak{p}} := (\mathcal{E} \neq \emptyset, \mathcal{E}) \quad \text{where } \mathcal{E} := \{\mathtt{N}(a, x, n, (\boxed{V}, O))\} \cap \dot{\mathfrak{h}}$$

3. refinement (i.e., adding of two new axioms) of the relation of data derivation $\vdash_a \subseteq \mathcal{H} \times \mathcal{M}$ in the semantics of the relational symbol $\mathtt{k}$ for individual knowledge with:
   (a) knowledge of temporal values $t \in \mathcal{TV}$: $\boxed{\overline{\mathfrak{h} \vdash_a t}}$

(b) adversarial break of short-term keys (k) enabled jointly by *key expiration* ($\mathsf{expired}(k)$) and the existence of a *ciphertext-only attack* on the key ($\mathsf{CA}(k)$):

$$\boxed{\overline{\mathfrak{h} \vdash_a k} \quad \begin{array}{l} \text{there is a prefix } \mathfrak{h}' \text{ of } \mathfrak{h}, \text{ and } t \in \mathcal{TV} \text{ s.t.} \\ \mathfrak{h}' \models \mathsf{CA}(k) \wedge t@\mathtt{Eve} \quad \text{and} \\ \mathfrak{h} \models \mathsf{expired}(k) \wedge \\ \qquad \exists t_v(t_v \ \mathsf{validityOf}\ k \wedge \exists t_n(t_n@\mathtt{Eve} \wedge t_v < t_n - t)) \end{array}}$$

where t_v denotes the duration of validity of the considered key (i.e., the strength[14] of the key), and $t_n - t$ the duration of the attack on the considered key (i.e., the time during which the corresponding ciphertext has been known to the adversary)[15]; and

$$\begin{aligned} \mathsf{CA}(k) &:= \exists m(m : \mathtt{SC}_k[\mathtt{M}] \cup \mathtt{S}_k[\mathtt{M}] \wedge \mathtt{Eve}\ \mathsf{k}\ m) \\ \mathsf{expired}(k) &:= \exists t_n(t_n@\mathtt{Eve} \wedge \exists t_e(k\ \mathsf{validUntil}\ t_e \wedge t_e < t_n)) \\ k\ \mathsf{validUntil}\ t_e &:= \exists t_b(k\ \mathsf{validBetween}\ (t_b, t_e)) \\ k\ \mathsf{validBetween}\ (t_b, t_e) &:= \exists a \exists x \exists o(a.x \circlearrowright k.(o, (t_b, t_e))) \\ t_v\ \mathsf{validityOf}\ k &:= k\ \mathsf{validBetween}\ (t_b, t_e) \wedge t_e - t_b = t_v \end{aligned}$$

4. refinement (i.e., one new conjunct) of the fundamental state of violation Σ with *key expiration* in the definition of the permission operator:

$$\Sigma := \exists(k : \mathtt{CK})(\mathtt{Eve}\ \mathsf{k}\ k \wedge \neg\, k\ \mathsf{ck}\ \mathtt{Eve} \wedge \boxed{\neg \mathsf{expired}(k)})$$

C.3 Expressiveness

Macro-definability of operators from general-purpose timed logics:

- *point*-parametrised temporal modalities (so-called *freeze quantifiers*):

$$\Box_t(\phi) := \boxplus(t@\mathtt{Eve} \rightarrow \phi) \qquad \Diamond_t(\phi) := \neg\Box_t(\neg\phi)$$

- *interval*-parametrised temporal modalities with an:
  - *absolute*-time understanding of (closed)[16] intervals $[t_1, t_2]$:

$$\Box^a_{[t_1,t_2]}(\phi) := \forall t(t_1 \leq t \leq t_2 \rightarrow \Box_t(\phi)) \qquad \Diamond^a_{[t_1,t_2]}(\phi) := \neg\Box^a_{[t_1,t_2]}(\neg\phi)$$

  - understanding of intervals that is *relative* to the current time $t@\mathtt{Eve}$:

$$\begin{aligned} \Box^r_{[t_1,t_2]}(\phi) &:= \forall t(t@\mathtt{Eve} \rightarrow \Box^a_{[t+t_1,t+t_2]}(\phi)) \\ \Diamond^r_{[t_1,t_2]}(\phi) &:= \forall t(t@\mathtt{Eve} \rightarrow \neg\Box^a_{[t+t_1,t+t_2]}(\neg\phi)) \end{aligned}$$

[14] corresponding to its length in a bit-string representation

[15] and during which the adversary has potentially been attacking — i.e., performing computations on — the ciphertext in order to recover the desired key

[16] and similarly for open intervals

The cryptographic states of affairs involving qualitative temporal modalities from [73, Section 2.1] can easily be adapted to the quantitative setting by replacing the qualitative temporal modalities by the above quantitative ones with actual time values (points and/or intervals) as desired.

Two more cryptographic states of affairs involving quantitative time:

- secrecy (at some point of time) of a possibly timed, confidential key k:

$$(k : \mathtt{CK} \wedge \mathsf{Eve}\ \mathsf{k}\ k \wedge \neg\, k\ \mathsf{ck}\ \mathsf{Eve}) \rightarrow \mathsf{expired}(k)$$

- successful ciphertext-only attack (break of a good key) k:

$$\exists m(m : \mathtt{SC}_k[\mathtt{M}] \cup \mathtt{S}_k[\mathtt{M}] \wedge \mathsf{Eve}\ \mathsf{k}\ m \wedge \neg\mathsf{expired}(k) \wedge \mathsf{Eve}\ \mathsf{k}\ k \equiv \mathsf{Eve}\ \mathsf{k}\ m)$$

  Notice that $\equiv$ is the *epistemic bi*-conditional; it says that the evidence required for Eve to know k is *exactly* (cf. 'bi-') the ciphertext m. This key break based on the knowledge of a single ciphertext (m) can easily be generalised to key break based on multiple ciphertexts ($m_1, \ldots, m_n$) by multiple existential quantification.
