# Key Recovery Attack against Secret-prefix Edon-R 

Gaëtan Leurent<br>École Normale Supérieure - Département d'Informatique, 45 rue d'Ulm, 75230 Paris Cedex 05, France<br>Gaetan.Leurent@ens.fr

#### Abstract

Edon- $\mathcal{R}$ is a SHA-3 candidate. In this paper we show that using Edon- $\mathcal{R}$ as a MAC with the secret prefix construction is unsafe. Our attack requires 2 queries, $2^{5 n / 8}$ computations, and negligible memory. This does not directly contradict the security claims of Edon- $\mathcal{R}$ or the NIST requirements for SHA-3, but we believe it shows a strong weakness in the design.

Key words: Hash functions, SHA-3, Edon- $\mathcal{R}$, MAC, secret prefix, key recovery

## 1 Description of Edon- $\mathcal{R}$

EdON- $\mathcal{R}$ is a wide-pipe iterative design, based on a compression function $\mathcal{R}$, with a final truncation $\mathcal{T}$. The Edon- $\mathcal{R}$ family is based on two main designs: Edon- $\mathcal{R} 256$ uses 32 -bits words, while EdON- $\mathcal{R} 512$ uses 64 -bit words. The compression function is based on a quasi-group operation $*$, which take two inputs $X$ and $Y$ in $\left(\mathbb{F}_{2}^{w}\right)^{8}($ i.e. $8 w$-bit words $)$ and compute one output in $\left(\mathbb{F}_{2}^{w}\right)^{8}$. It can be described as:

$$
\begin{aligned}
X * Y & =\pi_{1}\left(\pi_{2}(X)+\pi_{3}(Y)\right) \\
& =\pi_{1}\left(\pi_{2}(X)\right)+\pi_{1}\left(\pi_{3}(Y)\right) \\
& =Q_{0}\left(R_{0}\left(P_{0}(X)\right)\right)+Q_{1}\left(R_{1}\left(P_{1}(Y)\right)\right)
\end{aligned}
$$

where
-+ is a component-wise addition modulo $2^{w}$ ( $w$ is the word size);
$-\pi_{1}, \pi_{2}, \pi_{3}$ are the permutations used in the description of EdON- $\mathcal{R}$, we rewrite then with $Q_{i}$, $R_{i}$ and $P_{i}$;

- $P_{0}$ and $P_{1}$ are linear over $\mathbb{Z}_{2}^{8}$;
- $R_{0}$ and $R_{1}$ are component-wise rotations of $w$-bit words;
- $Q_{0}$ and $Q_{1}$ are linear over $\left(\mathbb{F}_{2}^{w}\right)^{8}$;
- We identify $\mathbb{Z}_{2^{w}}^{8}$ and $\left(\mathbb{F}_{2}^{w}\right)^{8}$ with the natural mapping.

## between them.

Note that quasi-group operation is very easy to invert.
The compression function takes as input $16 w$ bits of message $\left(M_{0}^{(i)}\right.$ and $\left.M_{1}^{(i)}\right)$ and $16 w$ bits of chaining value $\left(H_{0}^{(i)}\right.$ and $\left.H_{1}^{(i)}\right)$ and produces $16 w$ of new chaining value $\left(H_{0}^{(i+1)}\right.$ and $H_{1}^{(i+1)}$ ). The full compression function is described in Figure 1, where the symbol $\odot$ denotes different quasigroup operations based on $*$, with some permutations of the inputs. For more details, see [2].

Fig. 1. Edon- $\mathcal{R}$ compression function.

## 2 Previous analysis of Edon- $\mathcal{R}$

Previous work [34] have shown various weaknesses of the compression function:

- given $M_{0}^{(i)}, M_{1}^{(i)}, H_{0}^{(i+1)}$ and $H_{1}^{(i+1)}$, it is easy to compute $H_{0}^{(i)}$ and $H_{1}^{(i)}$;
- given $H_{0}^{(i)}, H_{1}^{(i)}, M_{0}^{(i)}$, and $H_{0}^{(i+1)}$, it is easy to compute $M_{1}^{(i)}$, and $H_{1}^{(i+1)}$;
- given $H_{1}^{(i+1)}, H_{0}^{(i)}$ and $M_{0}^{(i)}$, we can find a value of $H_{1}^{(i)}, H_{0}^{(i+1)}$, and $M_{1}^{(i)}$ with $2^{\text {n/2 }}$ operations.

These results can be used to mount various attacks on the hash function:

- We can apply generic attacks against single-pipe hash functions: multi-collisions, second preimages on long message, fixed points, ...
- There is a preimage attack with complexity $2^{2 n / 3}$ and $2^{2 n / 3}$ memory.

The preimage attack requires less computations than a generic attack, but the machine to carry out this attack might be more expensive than a machine to perform a parallel brute force, so it is unclear whether this should be considered as an attack.

However, these results show that the compression function of EdON- $\mathcal{R}$ is quite weak, and the security of Edon- $\mathcal{R}$ can't be based on a security proof of the Merkle-Damgård mode.

## 3 Secret-prefix MAC

We assume that Edon- $\mathcal{R}$ is used as a MAC with the secret-prefix construction: $\operatorname{MAC}_{k}(M)=$ Edon- $\mathcal{R}(k \| M)$. This kind of construction is used in some old protocols, like RFC2069 [1]. We assume that the key is padded to a full block, so that this construction is equivalent to using a secret IV $\left(H_{0}^{(0)}, H_{1}^{(0)}\right)$, and our attack will recover this secret IV. Note that this is not the case in RFC2069, and we cannot use our key-recovery attack in this situation.

It is well known that this construction is weak, because length extension attacks can be used for forgeries, but the key is not expected to leak. Moreover, EdON- $\mathcal{R}$ is a double-pipe design, so the length extension issue does not apply. In fact, this construction is secure if the hash function is double-pipe and the compression function is modeled as a random oracle.

## 4 Our Results

Our work shows that

- given $M_{0}^{(i)}, M_{1}^{(i)}, H_{1}^{(i)}$ and $H_{1}^{(i+1)}$, we can compute $H_{0}^{(i)}$ and $H_{0}^{(i+1)}$ with $2^{5 n / 8}$ operations.

This can be used to recover the key if EDON- $\mathcal{R}$ is used as a MAC with the secret-prefix construction. Our attack makes only two queries and needs $2^{5 n / 8}$ computations with negligible memory. It can easily be parallelized. This attack is the first attack on Edon- $\mathcal{R}$ to clearly beat parallel generic attacks. Our attack uses two related messages $M$ and $M^{\prime}$ such that $\operatorname{pad}(M)$ is a prefix of $\operatorname{pad}\left(M^{\prime}\right)$ and $\operatorname{pad}\left(M^{\prime}\right)$ is one block longer than $\operatorname{pad}(M)$.

## 5 Key Recovery

We will make two calls to the MAC, with two related messages, such that after the padding step, the second message is a suffix of the first one.

Then, we target the second compression function, and we have:

- $M_{0}^{(1)}, M_{1}^{(1)}$ are known;
- $H_{1}^{(1)}$ is known;
$-H_{1}^{(2)}$ is known.
We will show how to recover $H_{0}^{(1)}$. Then $H_{0}^{(0)}$ and $H_{1}^{(0)}$ can easily be recovered from $H_{0}^{(1)}, H_{1}^{(1)}$ and $M_{0}^{(0)}, M_{1}^{(0)}$. Since there are $8 w$ unknown bits in the input of the compression function $\left(H_{0}^{(i)}\right)$ and we know $8 w$ bits of the output of the compression function $\left(H_{1}^{(i+1)}\right)$, we expect one solution on average. In this setting, a preimage attack will be able to recover the value of $H_{0}^{(i)}$ and not merely $a$ value that gives the same output.

If we look at the description of the compression function [2], we have:

$$
\begin{aligned}
H_{1}^{(i+1)} & =H_{0}^{i+1} * X_{1}^{3} \\
& =\left(\overline{M_{0}^{(i)}} * X_{0}^{(3)}\right) *\left(X_{1}^{(2)} * X_{0}^{(3)}\right) \\
& =\left(\pi_{1}\left(\pi_{2}\left(\overline{M_{0}^{(i)}}\right)\right)+\pi_{1}\left(\pi_{3}\left(X_{0}^{(3)}\right)\right)\right) *\left(\pi_{1}\left(\pi_{2}\left(X_{1}^{(2)}\right)\right)+\pi_{1}\left(\pi_{3}\left(X_{0}^{(3)}\right)\right)\right. \\
& =\left(U+C_{0}\right) *\left(U+C_{1}\right)
\end{aligned}
$$

where $U=\pi_{1}\left(\pi_{3}\left(X_{0}^{(3)}\right)\right)$ is unknown, and $C_{0}=\pi_{1}\left(\pi_{2}\left(\overline{M_{0}^{(i)}}\right)\right), C_{1}=\pi_{1}\left(\pi_{2}\left(X_{1}^{(2)}\right)\right)$ are known constants.

If we are able to solve the equation $H=\left(U+C_{0}\right) *\left(U+C_{1}\right)$ where $U$ is the unknown, then we can recover $X_{0}^{(3)}$ from $U$, and this will give us $H_{0}^{(1)}$.

## 6 Solving the equation $H=\left(U+C_{0}\right) *\left(U+C_{1}\right)$

The main step of the attack is to solve the equation

$$
\begin{aligned}
H & =\left(U+C_{0}\right) *\left(U+C_{1}\right) \\
& =Q_{0}\left(R_{0}\left(P_{0}\left(U+C_{0}\right)\right)\right)+Q_{1}\left(R_{1}\left(P_{1}\left(U+C_{1}\right)\right)\right)
\end{aligned}
$$

More precisely, $P_{0}, P_{1}$ are defined by the following matrices over $\mathbb{Z}_{2^{32}}$ (i.e the sums are modular additions):

$$
P_{0}=\left[\begin{array}{llllllll}
1 & 1 & 1 & 0 & 1 & 0 & 0 & 1 \\
1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 \\
1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 \\
0 & 0 & 1 & 1 & 0 & 1 & 1 & 1 \\
0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 \\
1 & 0 & 1 & 1 & 1 & 1 & 0 & 0 \\
1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\
0 & 0 & 1 & 1 & 1 & 1 & 1 & 0
\end{array}\right]
$$

We will use three vectors $U_{0}, U_{1}, U_{2}$ in the kernels of some submatrices of $P_{0}$ and $P_{1}$ :
$U_{0}=\left[\begin{array}{llllcccc}0 & 0 & 0 & 0 & 0 & 0 & 1 & -1\end{array}\right]$
$U_{1}=\left[\begin{array}{llllll}2 & 2 & 2 & 2 & 2^{31}-32^{31}-3 & 0 \\ 2^{31}-1\end{array}\right]$
$U_{2}=\left[\begin{array}{llllll} & =0 & 0 & 0 & 2^{31}-1 & 2^{31}\end{array} 0\right.$

Then we have (the stars represent any non-zero value):

$$
\left.\begin{array}{ll}
P_{0} \cdot U_{0}=\left[\begin{array}{llll}
* * & 0 & 0 & * \\
0 & 0 & *
\end{array}\right] & P_{1} \cdot U_{0}=\left[\begin{array}{llllll}
* * & 0 & 0 & 0 & 0 & 0
\end{array}\right]
\end{array}\right]
$$

$Q_{0}, Q_{1}$ are defined by the following matrices over $\mathbb{F}_{2}^{8}$ (i.e the sums are exclusive or):

$$
Q_{0}=\left[\begin{array}{llllllll}
1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 1 & 1 & 1 & 0 & 0 & 0 \\
1 & 1 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 0 & 1 & 1 & 0 \\
0 & 0 & 1 & 0 & 0 & 1 & 1 & 0 \\
0 & 0 & 1 & 1 & 0 & 1 & 0 & 0
\end{array}\right]
$$

$$
Q_{1}=\left[\begin{array}{llllllll}
1 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 1 & 1 \\
1 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\
0 & 1 & 1 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 1 & 0 & 1 & 0 \\
0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 \\
0 & 0 & 0 & 0 & 1 & 0 & 1 & 1
\end{array}\right]
$$

Due to the positions of the zeros in $P_{i} \cdot U_{j}$, we have, for all $\alpha, \beta \in \mathbb{Z}_{2^{32}}$ :

$$
\left.\begin{array}{rl}
Q_{0}\left(R_{0}\left(P_{0}\left(X+\alpha U_{0}\right)\right)\right) \oplus Q_{0}\left(R_{0}\left(P_{0}(X)\right)\right) & =\left[\begin{array}{ll}
* * * * * & 0
\end{array} 0_{0}\right.
\end{array}\right]
$$

This proves that the vectors $U_{0}, U_{1}, U_{2}$ do not affect some of the output words:

$$
\begin{align*}
& \left(X+\alpha U_{0}\right) *\left(Y+\beta U_{0}\right) \oplus X * Y=[* * * * * 0 l l  \tag{1}\\
& \left(X+\alpha U_{1}\right) *\left(Y+\beta U_{1}\right) \oplus X * Y=[* * * * * 0 * 0]  \tag{2}\\
& \left(X+\alpha U_{2}\right) *\left(Y+\beta U_{2}\right) \oplus X * Y=[* * * * * * * 0] \tag{3}
\end{align*}
$$

This is a very important part of the attack, so let us explain into more detail what equation (3) means. Using notations similar to the one from [2], the last output word of $X * Y$ is computed as:

$$
(X * Y)^{[7]}=\left(T_{X}^{[2]} \oplus T_{X}^{[3]} \oplus T_{X}^{[5]}\right)+\left(T_{Y}^{[4]} \oplus T_{Y}^{[6]} \oplus T_{Y}^{[7]}\right)
$$

where

$$
\begin{aligned}
& T_{X}^{[2]}=\left(X^{[0]}+X^{[1]}+X^{[4]}+X^{[6]}+X^{[7]}\right) \lll 8 \\
& T_{X}^{[3]}=\left(X^{[2]}+X^{[3]}+X^{[5]}+X^{[6]}+X^{[7]}\right) \lll 13 \\
& T_{X}^{[5]}=\left(X^{[0]}+X^{[2]}+X^{[3]}+X^{[4]}+X^{[5]}\right) \lll 22 \\
& T_{Y}^{[4]}=\left(Y^{[0]}+Y^{[1]}+Y^{[3]}+Y^{[4]}+Y^{[5]}\right) \lll 15 \\
& T_{Y}^{[6]}=\left(Y^{[1]}+Y^{[2]}+Y^{[5]}+Y^{[6]}+Y^{[7]}\right) \lll 25 \\
& T_{Y}^{[7]}=\left(Y^{[0]}+Y^{[3]}+Y^{[4]}+Y^{[6]}+Y^{[7]}\right) \lll 27
\end{aligned}
$$

We now consider $X^{\prime}=X+\alpha U_{2}$ and $Y^{\prime}=Y+\beta U_{2}$ :

$$
\left(X^{\prime} * Y^{\prime}\right)^{[7]}=\left(T_{X}^{\prime[2]} \oplus T_{X}^{\prime[3]} \oplus T_{X}^{\prime[5]}\right)+\left(T_{Y}^{\prime[4]} \oplus T_{Y}^{\prime[6]} \oplus T_{Y}^{\prime[7]}\right)
$$

where

$$
\begin{aligned}
& T_{X}^{\prime 2]}=\left(X^{[0]}+\alpha+X^{[1]}+X^{[4]}+\alpha\left(2^{31}-1\right)+X^{[6]}+X^{[7]}+\alpha 2^{31}\right) \lll 8 \\
& T_{X}^{\prime 3]}=\left(X^{[2]}+X^{[3]}+X^{[5]}+\alpha 2^{31}+X^{[6]}+X^{[7]}+\alpha 2^{31}\right) \lll 13 \\
& T_{X}^{\prime[5]}=\left(X^{[0]}+\alpha+X^{[2]}+X^{[3]}+X^{[4]}+\alpha\left(2^{31}-1\right)+X^{[5]}+\alpha 2^{31}\right) \lll 22 \\
& T_{Y}^{\prime 4]}=\left(Y^{[0]}+\beta+Y^{[1]}+Y^{[3]}+Y^{[4]}+\beta\left(2^{31}-1\right)+Y^{[5]}+\beta 2^{31}\right) \lll 15 \\
& T_{Y}^{\prime 6]}=\left(Y^{[1]}+Y^{[2]}+Y^{[5]}+\beta 2^{31}+Y^{[6]}+Y^{[7]}+\beta 2^{31}\right) \lll 25 \\
& T_{Y}^{\prime 7]}=\left(Y^{[0]}+\beta+Y^{[3]}+Y^{[4]}+\beta\left(2^{31}-1\right)+Y^{[6]}+Y^{[7]}+\beta 2^{31}\right) \lll 27
\end{aligned}
$$

We see that the $\alpha$ and $\beta$ terms cancels out:

$$
\begin{array}{lll}
T_{X}^{[2]}=T_{X}^{\prime[2]} & T_{X}^{[3]}=T_{X}^{\prime[3]} & T_{X}^{[5]}=T_{X}^{\prime[5]} \\
T_{Y}^{[4]}=T_{Y}^{\prime[4]} & T_{Y}^{[6]}=T_{Y}^{\prime[6]} & T_{Y}^{[7]}=T_{Y}^{\prime[7]}
\end{array}
$$

and as a consequence

$$
\left(X^{\prime} * Y^{\prime}\right)^{[7]}=(X * Y)^{[7]}
$$

This works because $U_{2}$ was chosen in the kernel of the linear forms that define $T_{X}^{[2]}, T_{X}^{[3]}, T_{X}^{[5]}$, $T_{Y}^{[4]}, T_{Y}^{[6]}$, and $T_{Y}^{[7]}$. Similarly, $U_{1}$ is in the kernel of the linear forms involved in the computation of $(X * Y)^{[5,7]}$ and $U_{0}$ is in the kernel of the linear forms involved in the computation of $(X * Y)^{[5,6,7]}$.

Thanks to this property, we can do an exhaustive search with early abort. We extend $U_{0}, U_{1}, U_{2}$ into a basis $U_{0}, U_{1}, \ldots U_{7}$ of $\mathbb{Z}_{2^{32}}^{8}$, and we will represent $U$ in this basis: $U=\sum_{i=0}^{7} \alpha_{i} U_{i}$. We define $V=\left(U+C_{0}\right) *\left(U+C_{1}\right)$. Due to the properties of $U_{0}, U_{1}, U_{2}$, we know that:

- $\alpha_{0}$ has no effect on $V^{[5]}, V^{[6]}$ and $V^{[7]}$;
$-\alpha_{1}$ has no effect on $V^{[5]}$ and $V^{[7]}$;
$-\alpha_{2}$ has no effect on $V^{[7]}$.
The full algorithm is given by Algorithm 1 and is quite simple. We first iterate over $\alpha_{3}, \alpha_{4}, \ldots \alpha_{7}$ and we filter the elements such that $V=\left(U+C_{0}\right) *\left(U+C_{1}\right)$ matches $H$ on the last coordinates. If it does not match, we don't need to iterate over $\alpha_{0}, \alpha_{1}, \alpha_{2}$ because this wont modify $V^{[7]}$, so we can abort this branch. For the choices that match, we iterate over $\alpha_{2}$ and check $V^{[5]}$. If it matches $H^{[5]}$, we iterate over $\alpha_{1}$ and check $V^{[6]}$. If it matches $H^{[5]}$, we can then iterate over $\alpha_{0}$.

The time complexity is $2^{5 w}=2^{5 n / 8}$ :

- the first loop is executed $2^{5 w}$ times;
- each matching reduces the number of candidates to $2^{4 w}$;
- each subsequent loop raises the number of candidates to $2^{5 w}$.

The memory requirement are negligible because we do not need to store a list a candidate, we just iterate over a set and filter out the candidates as they come.

Once we have recovered $U=\pi_{1}\left(\pi_{3}\left(X_{0}^{(3)}\right)\right)$, it is easy to invert the permutations and recover $X_{0}^{(3)}$. From that we find $H_{0}^{(i)}$ by inverting a quasi-group operation, and we have all the variables of the compression function. We can then recover the key $H_{0}^{(0)}, H_{1}^{(0)}$ by inverting the first compression function (it is easy when the output and the message are known)

```
Algorithm 1 Solving \(H=\left(U+C_{0}\right) *\left(U+C_{1}\right)\)
Input: \(C_{0}, C_{1}, H\)
Output: \(U\)
    for all \(\alpha_{3}, \alpha_{4}, \ldots \alpha_{7} \in \mathbb{Z}_{2^{32}}\) do
        \(U \leftarrow \sum_{i=3}^{7} \alpha_{i} U_{i}\)
        \(V \leftarrow\left(U+C_{0}\right) *\left(U+C_{1}\right)\)
        if \(V^{[7]}=H^{[7]}\) then
            for all \(\alpha_{2} \in \mathbb{Z}_{2^{32}}\) do
                \(U \leftarrow \sum_{i=2}^{7} \alpha_{i} U_{i}\)
                \(V \leftarrow\left(U+C_{0}\right) *\left(U+C_{1}\right)\)
                    if \(V^{[5]}=H^{[5]}\) then
                    for all \(\alpha_{1} \in \mathbb{Z}_{2^{32}}\) do
                    \(U \leftarrow \sum_{i=1}^{7} \alpha_{i} U_{i}\)
                        \(V \leftarrow\left(U+C_{0}\right) *\left(U+C_{1}\right)\)
                        if \(V^{[6]}=H^{[6]}\) then
                            for all \(\alpha_{0} \in \mathbb{Z}_{2^{32}}\) do
                        \(U \leftarrow \sum_{i=0}^{7} \alpha_{i} U_{i}\)
                        \(V \leftarrow\left(U+C_{0}\right) *\left(U+C_{1}\right)\)
                                if \(V=H\) then
                            \(U\) is a solution
```
