email : dihuo377@163.com

**Abstract.**This paper presents a efficient proposal for iterating hash functions to prevent the main of generic attacks such as Multicollisions Attack,Second Preimage Attack and Herding Attack.Based on this proposal,it's possible that a secure hash function can be built with iterating compression functions .

The proposal mainly contains a method called " Shifting Whole Message" ,it regroups the cascaded messages to be new blocks and makes the known results of the pre-computed blocks noneffective .

**keywords:** hash function ,iterating ,shift ,regrouped block,pre-computed

## 1 Introduction:

Since 2004,some of the existing hash functions MD5,SHA0,SHA1 [1][2]are broken. The existing hash functions are built by a same structure called Merkle-Damgaard Structure ,which is made of iterating compression functions.Many papers have shown the weakness of the structure and many generic attacks are given.It seems that iterating hash functions can hardly be secure anymore.

This paper presents a efficient proposal for iterating hash function to prevent those generic attacks which includes Multicollisions Attack [3],Second Preimage Attack [4]and Herding Attack [5],of course, we need a stronger compression function to avert the differential attacks on collision resistance .

The proposal is made up of two parallel compression functions, one acts in a normal mode,and another acts in a particular mode which contains a method called "Shifting Whole Message".

A normal pretreatment of a hash function is:after padding and appending length,a message is formatted as  $16m$  64-bit(or 32-bit) words,and it is grouped to be  $m$  blocks,each block contains 16 64-bit(or 32-bit )words. we add a pretreatment called "Shifting Whole Message":

an original message : $x_0, x_1, \dots, x_i, \dots, x_{16m-1}$

Cut  $s$  words from the head ,and link them to the end,ie.,the whole message is shifted to the left for  $s$  words.

Set the shift parameter  $s = 8m + 1$  ,if  $m$  is a odd number;

and set  $s = 8m + 7$  if  $m$  is a even number. For example,we consider  $m$  is a odd

number.

The original message is:

$$x_0, x_1, \dots, x_{8m}, x_{8m+1}, \dots, x_{16m-1}$$

The shifted message is:

$$x_{8m+1}, \dots, x_{16m-1}, x_0, x_1, \dots, x_{8m}$$

This method is different from the previous ones (such as square-free dithering[6]), it makes the blocks regrouped and makes the new blocks staggered, then, each block is different from the original corresponding one. Once the message blocks are cascaded, each block will change into a new block, the previous known result of a block can't be used again, and we can avert the attacks which using known result by pre-computing blocks.

The rest of this paper, we first explain the method "Shifting Whole Message" to prevent those attacks, then, we give a more detailed proposal.

## 2 Shift Mode And The Generic Attacks

For a message  $x$ , after padding and appending length, its length is  $16m \times 64$  bits or  $16m \times 32$  bits, (the succedent we assume it 64bits), for the hash function  $H(x)$  of the M-D structure, its compression function is  $f$ , the message is formatted as  $16m$  64-bit words:  $x_0, x_1, \dots, x_i, \dots, x_{16m-1}$ , i.e., the message is made up of  $m$  blocks and each block contains 16 64-bit words, for  $H(x)$ :

$CV_i$  = Chaining variable,  $CV_0 = IV$  (given Initial Value)

$X[i]$  = the  $i$ th block

$CV_i = f(CV_{i-1}, X[i])$

$H(x) = CV_m$

We can see, the fixed message-blocks  $X[i]$  are computed one by one, the attackers achieve by pre-computing the message-blocks, using known result of message-blocks, matching and yielding the chaining variables. We now use the method "Shifting Whole Message" and to see the generic attacks.

### 2.1 The Setting of Shifting Whole Message

#### 2.1.1 The Setting

For a  $m$  blocks message, we set the shift parameter  $s = 8m + 1$ , if  $m$  is a odd number; and set  $s = 8m + 7$  if  $m$  is a even number.

For example,  $m = 1$ , i.e., the message is a single block. The original message is:

$$x_0, x_1, \dots, x_8, x_9 \dots x_{15}$$

The shift parameter  $s = 8m + 1 = 8 \times 1 + 1 = 9$  ( $m$  is a odd number), we cut  $9(s = 9)$  words ( $x_0, x_1, \dots, x_7, x_8$ ) from the head and link them to the end.

where, " | " denotes the cutting point:

the original message :  $x_0, x_1, \dots, x_8, |x_9 \dots x_{15}$

And the shifted message:  $|x_9 \dots x_{15}, x_0, x_1, \dots, x_7, x_8$

The setting of the shift parameter makes the cutting point always on the center block when  $m$  is an odd number, or makes it on the right one of the two center blocks when  $m$  is an even number.

For a two-block message, we assume it contains Block  $A$  and  $B$ :

Block  $A$  :  $x_0, x_1, \dots, x_7, x_8, \dots, x_{15}$

Block  $B$  :  $y_0, y_1, \dots, y_7, y_8, \dots, y_{15}$

Of course, if the single block  $A$  is shifted for pre-computing, it is:

$x_9, \dots, x_{15}, x_0, x_1, \dots, x_7, x_8$ , and we write this single shifted block as  $\widehat{A}$ .

The same, if the single block  $B$  is shifted for pre-computing, it is:

$\widehat{B}(y_9, \dots, y_{15}, y_0, y_1, \dots, y_7, y_8)$

Their output are marked with subscript "S", e.g.,  $CV_{S1}$ .

Pre-compute  $CV_{S1}$  and  $CV_{S2}$ :

$$CV_{S1} = f(IV, \widehat{A}) = f(IV, (x_9 \dots x_{15}, x_0, x_1, \dots, x_8))$$

$$CV_{S2} = f(CV_{S1}, \widehat{B}) = f(CV_{S1}, (y_9, \dots, y_{15}, y_0, y_1, \dots, y_8))$$

Now, if the two single blocks are cascaded to be a two-block message, then the shift parameter  $s = 8m + 7 = 8 \times 2 + 7 = 23$  ( $m = 2$ , it is an even number).

We cut 23 ( $s = 23$ ) words from the head and link them to the end.

The original two-block message is:

$(x_0, x_1, \dots, x_7, x_8, x_9 \dots x_{15})(y_0, y_1, \dots, y_6 | y_7, \dots, y_{15})$  (where  $|$  denotes the cutting point)

And the shifted two-block message is:

$(y_7, \dots, y_{15}, x_0, x_1, \dots, x_6)(x_7, \dots, x_{15}, y_0, y_1, \dots, y_6)$

We can see that the two new blocks of the cascaded message are staggered. The first new block contains elements of Block  $B$ , and the second new block contains elements of Block  $A$ , so the two new blocks are different from either of Block  $A$  or Block  $B$ , we call the new blocks *regrouped blocks*.

Let  $\widehat{BA}$  denotes the first regrouped block  $(y_7, y_8, \dots, y_{15}, x_0, x_1, \dots, x_6)$ .

$\widehat{BA}$  means the elements are from Block  $B$  and Block  $A$ .

$\widehat{AB}$  denotes the second regrouped block  $(x_7, \dots, x_{15}, y_0, y_1, \dots, y_6)$ , for these cascaded blocks, their output are marked with subscript "C", e.g.,  $CV_{C1}$ .

$CV_{C1}$  denotes the output of the first block in shift mode:

$$CV_{C1} = f(IV, \widehat{BA}) = f(IV, (y_7, \dots, y_{15}, x_0, x_1, \dots, x_6)).$$

$CV_{C2}$  denotes the output of the second new block:

$$CV_{C2} = f(CV_{C1}, \widehat{AB}) = f(CV_{C1}, (x_7 \dots x_{15}, y_0, y_1, \dots, y_6)),$$

in normal mode, pre-compute  $CV_1$  and  $CV_2$ :

$$CV_1 = f(IV, A) = f(IV, (x_0, x_1, \dots, x_{15}))$$

$CV_2 = f(CV_1, B) = f(CV_1, (y_0, y_1, \dots, y_{15}))$   
 Obviously,  $CV_{C1} \neq CV_1$ ;  $CV_{C1} \neq CV_{S1}$  and  $CV_{C2} \neq CV_2, CV_{C2} \neq CV_{S2}$

So, pre-computing the two single shifted blocks  $f(IV, \widehat{A})$  and  $f(CV_{S1}, \widehat{B})$  or pre-computing the two original blocks  $f(IV, A)$  and  $f(CV_1, B)$  are of no use in this case.

### 2.1.2 Some Symbols And Explanation

Two Types of Message

The first one ,Original Messages.

Two capital letter, e.g., AB or A-B denotes the original message ,it's beginning is Block A and the ending is Block B,e.g.: a 5-block Message AB :A,A<sub>1</sub>,A<sub>2</sub>,A<sub>3</sub>,B

The another one,Shifted Message,e.g.:

$\widehat{A.n}$  denotes the shifted message, the shift version from the first n blocks of the original message, the beginning is Block A,and it contains n blocks.the similar, $\widehat{A - B}$  is ,the ending of it's corresponding original message is Block B.

*E.g. an original message , Message AB :A,A<sub>1</sub>,A<sub>2</sub>,A<sub>3</sub>,B*

$\widehat{A.3}$  the shifted message comes from the 3 original blocks:A,A<sub>1</sub>,A<sub>2</sub>,and the first one is A.

$\widehat{A - A_2}$  the shifted message comes from the original blocks: A,A<sub>1</sub>,A<sub>2</sub> ,the first one is A and the last one is A<sub>2</sub>.

Two Types of Blocks

the original blocks ,e.g.A,B,C

the regrouped blocks,e.g. $\widehat{AB}, \widehat{BC}, \widehat{CA}$

Take note of the difference of  $\widehat{AB}$  and  $\widehat{A - B}$ ,the first one denotes a regrouped block,and the second one denotes a shifted message.

If the shifted message was used for precomputing, when it is cascaded with another message it will be re-shifted and regrouped.

There maybe a bit difference between the regrouped blocks of the same name,e.g.:

3 blocks,A(x<sub>0</sub>, x<sub>1</sub>, ..., x<sub>15</sub>),B(y<sub>0</sub>, y<sub>1</sub>, ..., y<sub>15</sub>) and C(z<sub>0</sub>, z<sub>1</sub>, ..., z<sub>15</sub>).

2-block Message A - B and 3-block message A - C.

For message A - B:

$A - B(x_0, x_1, \dots, x_{15}, y_0, y_1, \dots, y_6 | y_7, \dots, y_{15}),$

$s = 8m + 7 = 8 \times 2 + 7 = 23,$ so

$\widehat{A - B}(y_7, \dots, y_{15}, x_0, x_1, \dots, x_6)(x_7, \dots, x_{15}, y_0, y_1, \dots, y_6)$

ie., $\widehat{A - B}(\widehat{BA}, \widehat{AB})$

The regrouped block  $\widehat{AB}$  is:(x<sub>7</sub>, ..., x<sub>15</sub>, y<sub>0</sub>, y<sub>1</sub>, ..., y<sub>6</sub>)

For message  $A-C: A-C(x_0, x_1, \dots, x_{15}, y_0, y_1, \dots, y_7, y_8, |y_9, \dots, y_{15}, z_0, z_1, \dots, z_{15})$   
 $s = 8m + 1 = 8 \times 3 + 1 = 25$ , so

$\overbrace{A-C}(y_9, \dots, y_{15}, z_0, z_1, \dots, z_8)(z_9, \dots, z_{15}, x_0, x_1, \dots, x_8)(x_9, \dots, x_{15}, y_0, y_1, \dots, y_8, )$   
 i.e.,  $\overbrace{A-C}(\overbrace{BC}, \overbrace{CA}, \overbrace{AB})$

The regrouped block  $\overbrace{AB}$  is:  $(x_9, \dots, x_{15}, y_0, y_1, \dots, y_8, )$

Obviously, the two blocks  $\overbrace{AB}$  are different. In the following, we will ignore this difference.

### 2.1.3 About the Proposal

Our proposal mainly contains the cascading of the two parallel compression functions  $f_1$  and  $f_2$  :

$f_1$  acts the original blocks,  $f_2$  acts the shifted blocks, and the chaining values outputted are the modulo additions of theirs.  $f_1, f_2$  can be similar compression functions which output chaining-value with same length (and even  $f_1, f_2$  they can be a same function).

The followed is analysis of Multicollisions in shift mode.

## 2.2 Multicollisions In Shift Mode

For Multicollisions [3], We quote *Multicollisions in Iterated Hash Functions Application to Cascaded Constructions*: In a normal iterating function with M-D construction, recall that a collision is a pair of different messages  $M$  and  $M'$  such that  $H(M) = H(M')$ . Due to the birthday paradox, there is a generic attack that find collisions after about  $2^{n/2}$  evaluations of the hash function, where  $n$  is the size in bits of the hash values. If there are  $t$  collisions of  $t$  pairs of different messages, then, there can construct multicollisions of  $2^t$  collisions. First is how 4-collisions can be obtained, assume that two different blocks,  $A$  and  $A'$  that yield a collision, i.e.  $f(IV, A) = f(IV, A')$ . Let  $z$  denotes this common value and find two other blocks  $B$  and  $B'$  such that  $f(z, B) = f(z, B')$ . Put these two steps together to obtain the following 4-collision:

$$f(f(IV, A), B) = f(f(IV, A), B') = f(f(IV, A'), B) = f(f(IV, A'), B')$$

And  $2^t$ -collision can obtain by analogy.

Now, in shift mode, we set the shift parameter  $s = 8m + 1$ , if  $m$  is a odd number; and set  $s = 8m + 9$  if  $m$  is a even number.

Obviously, for each the precomputing of the single block,  $m = 1$ , and the shift parameter  $s = 8m + 1$ . i.e.,  $s = 8 \times 1 + 1 = 9$

For example, we show the message made up of two blocks, we also assume the previous two different single blocks  $A$  and  $A'$  that yield a collision, and  $B, B'$  yield another collision at  $z$ .  $A(x_0, x_1, \dots, x_6, x_7, \dots, x_{15})$  denotes the elements of block

$A$ , by the same, there are  $B(y_0, y_1, \dots, y_6, y_7, \dots, y_{15})$ ,  $A'(x'_0, x'_1, \dots, x'_6, x'_7, \dots, x'_{15})$ , and  $B'(y'_0, y'_1, \dots, y'_6, y'_7, \dots, y'_{15})$ .

This is a message cascaded by two blocks, which  $m = 2$  ( $m$  is an even number), so the shift parameter  $s = 8m + 7$ . i.e.,  $s = 8 \times 2 + 7 = 23$ .

The original message  $AB$  is: | denotes the cutting point):

$$(x_0, x_1, \dots, x_7, x_8, \dots, x_{15})(y_0, y_1, \dots, y_6, |y_7, \dots, y_{15})$$

We cut the first 23 ( $s = 8 \times 2 + 7 = 23$ ) words of  $x_0, x_1, \dots, x_7, x_8, \dots, x_{15}, y_0, y_1, \dots, y_6$  and link them to the end.

The shifted message  $\widehat{A - B}$  is:

$$(y_7, \dots, y_{15}, x_0, x_1, \dots, x_6)(x_7, \dots, x_{15}, y_0, y_1, \dots, y_6)$$

We show the blocks in three situations, the first is each the original block, the second is the each single block shifted for precomputing, and the third is each of the two cascading blocks which are regrouped by shift. For  $A, B$ :

	Block1	Block2
original	$A(x_0, x_1, \dots, x_6, x_7, \dots, x_{15})$	$B(y_0, y_1, \dots, y_6, y_7, \dots, y_{15})$
single	$\widehat{A}(x_9, \dots, x_{15}, x_0, x_1, \dots, x_8)$	$\widehat{B}(y_9, \dots, y_{15}, y_0, y_1, \dots, y_8)$
cascaded:	$\widehat{BA}(y_7, \dots, y_{15}, x_0, x_1, \dots, x_6)$	$\widehat{AB}(x_7, \dots, x_{15}, y_0, y_1, \dots, y_6)$

By analogy, we link  $A', B$

	Block1	Block2
original	$A'(x'_0, x'_1, \dots, x'_6, x'_7, \dots, x'_{15})$	$B(y_0, y_1, \dots, y_6, y_7, \dots, y_{15})$
single	$\widehat{A'}(x'_9, \dots, x'_{15}, x'_0, x'_1, \dots, x'_8)$	$\widehat{B}(y_9, \dots, y_{15}, y_0, y_1, \dots, y_8)$
cascaded:	$\widehat{BA'}(y_7, \dots, y_{15}, x'_0, x'_1, \dots, x'_6)$	$\widehat{A'B}(x'_7, \dots, x'_{15}, y_0, y_1, \dots, y_6)$

We assume the two different single blocks,  $\widehat{A}$  and  $\widehat{A'}$  that yield a collision by precomputing, (Of course, this is in shift mode, we can also assume it in normal mode, that two original blocks  $A$  and  $A'$  yield a collision by precomputing. the followed we'll only consider precomputing in shift mode.)

$$f(IV, \widehat{A}) = f(IV, \widehat{A'}) = z$$

$$\text{i.e., } f(IV, (x_9, \dots, x_{15}, x_0, x_1, \dots, x_8)) = f(IV, (x'_9, \dots, x'_{15}, x'_0, x'_1, \dots, x'_8)) = z$$

For cascaded message  $A - B$ , the first regrouped block is:

$$\widehat{BA}(y_7, \dots, y_{15}, x_0, x_1, \dots, x_6)$$

For cascaded message  $A' - B$ , the first regrouped block is:

$$\widehat{BA'}(y_7, \dots, y_{15}, x'_0, x'_1, \dots, x'_6)$$

Obviously,  $\widehat{BA} \neq \widehat{BA'}$ ; Synchronously,  $\widehat{BA} \neq \widehat{A}$ ;  $\widehat{BA'} \neq \widehat{A'}$ , we can't get

$$f(IV, \widehat{BA}) = f(IV, \widehat{BA'}) = z \text{ by assuming } f(IV, \widehat{A}) = f(IV, \widehat{A'}) = z.$$

The first regrouped blocks are also different from the two known original blocks

A or A'.

Therefore, the first step that  $f(IV, \widehat{BA}) = f(IV, \widehat{BA'}) = z$  is false, and we can't use the result of known collision that  $f(IV, \widehat{A}) = f(IV, \widehat{A'}) = z$ .

Since they don't meet the same output of chaining value  $z$ , Synchronously in the shift mode of cascading, their second new blocks:

$\widehat{AB}(x_7, \dots, x_{15}, y_0, y_1, \dots, y_6)$  and  $\widehat{A'B}(x'_7, \dots, x'_{15}, y_0, y_1, \dots, y_6)$  are also different. so, the second step, we can't get that  $f(z, \widehat{AB}) = f(z, \widehat{A'B})$ .

Therefore, we can't get:  $f(IV, A - B) = f(IV, A' - B)$

If assume that the two original blocks A and A' yield a collision by pre-computing in normal mode, we can get the same result.

By analogy, we also can't get the 4-collision :

$$f(IV, A - B) = f(IV, A - B') = f(IV, A' - B) = f(IV, A' - B')$$

By the same way, in shift mode, that the Multicollisions Application to Cascaded Constructions, and  $2^t$ -collision can obtain are false.

We will farther expound in the below.

### 2.3 Herding Attacks And Shift Mode

An attacker who can find many collisions on the hash function by brute force can first provide the hash of a message. The attacker first does a large pre-computation, and then commits to a hash value  $h$ . Later, upon being challenged with a prefix  $P$ , the attacker constructs a suffix  $S$  such that  $\text{hash}(P \parallel S) = h$ . Kelsey and Kohno, Their paper introduced the "diamond structure" [5], which is reminiscent of a complete binary tree. It is a  $2^t$  multi-collision in which each message in the multi-collision has a different initial chaining value, and which is constructed in the pre-computation step of the attack. The herding attack on an  $n$ -bit hash function requires approximately  $2^{2n/3+1}$  work [4].

According to the previous result, we can see that pre-computation of a block can't be used in a cascaded message in shift mode. Now, we consider it again by "Shifting Whole Message".

For simplicity, assume the original blocks are  $P(x_0, x_1, \dots, x_{15})$  and  $S(y_0, y_1, \dots, y_{15})$

The single shifted message  $\widehat{P}$  is:  $\widehat{P}(x_9, \dots, x_{15}, x_0, x_1, \dots, x_8)$

The single shifted message  $\widehat{S}$  is:  $\widehat{S}(y_9, \dots, y_{15}, y_0, y_1, \dots, y_8)$

Assume that by pre-computing and matching, we get  $f(IV, \widehat{P}) = z_1$  and  $f(z_1, \widehat{S}) = h$ , then we'll see whether we can get that:  $f(IV, P \parallel S) = h$ .

$$f(IV, \widehat{P}) = f(IV, (x_9, \dots, x_{15}, x_0, x_1, \dots, x_8)) = z_1;$$

$$f(z_1, \widehat{S}) = f(z_1, (y_9, \dots, y_{15}, y_0, y_1, \dots, y_8)) = h$$

Now,  $P$  and  $S$  are cascaded to be a new message " $P \parallel S$ ", we write it as " $P - S$ " or " $PS$ ".

The shift parameter  $s$  of the cascaded message  $PS : s = 8m + 7 = 8 \times 2 + 7 = 23$ , which  $m = 2$ .

the original message is:  $(x_0, x_1, \dots, x_6, x_7, \dots, x_{15})(y_0, y_1, \dots, y_6, |y_7, \dots, y_{15})$

And the shifted message of  $PS$  is:

$$(y_7, \dots, y_{15}, x_0, x_1, \dots, x_6), (x_7, \dots, x_{15}, y_0, y_1, \dots, y_6)$$

$\widehat{SP}$  denotes the first regrouped block :  $\widehat{SP}(y_7, \dots, y_{15}, x_0, x_1, \dots, x_6)$

$\widehat{PS}$  denotes the second regrouped block:  $\widehat{PS}(x_7, \dots, x_{15}, y_0, y_1, \dots, y_6)$

Obviously,  $\widehat{SP}$  is quite different from the single shifted block  $\widehat{P}$ , so, the first step,  $f(IV, \widehat{SP}) \neq f(IV, \widehat{P}) = z_1$ ; synchronously, for the second blocks  $\widehat{PS} \neq \widehat{S}$ .

Even though  $f(z_1, \widehat{S}) = h$ , We can't get  $f(z_1, \widehat{PS}) = h$ , ie., we can't get  $f(IV, PS) = h$ .

If the pre-computing is in normal mode, that we get  $f(IV, P) = z_1$ ,  $f(z_1, S) = h$ , By analogy, we'll have the same result. It means, that to build a binary tree of multi-collision by pre-computing the original blocks or the single-shifted blocks is useless.

In fact, our proposal mainly contains the cascading of two parallel compression functions  $f_1$  and  $f_2$ ;  $f_1$  acts the original blocks in normal mode,  $f_2$  acts the regrouped blocks in shift mode, the chaining values outputted are the modulo additions of theirs.

The message in shift mode is a shift version of the original message (by shifting it to left for  $(8m + 1)$  or  $(8m + 7)$  words), and we can also regard the original message as a shift version of the shifted message (by shifting it to right for  $(8m - 1)$  or  $(8m - 7)$  words), ie., they are the shift versions each other.

Consider a  $m$ -block message  $B$ :

If  $m$  is an odd number, then Block  $B_{\frac{m+1}{2}}$  is the center one, and the cutting point is just on it.

$$B(B_1, B_2, \dots, B_{\frac{m+1}{2}}, B_{\frac{m+3}{2}}, \dots, B_m)$$

The shifted message is:

$$\widehat{B.m}(\widehat{B_{\frac{m+1}{2}} B_{\frac{m+3}{2}}}, \dots, \widehat{B_{m-1} B_m}, \widehat{B_m B_1}, \dots, \widehat{B_{\frac{m-1}{2}} B_{\frac{m+1}{2}}}) \dots \dots \dots \text{Formula(1)}$$

If  $m$  is an even number, where block  $B_{\frac{m}{2}+1}$  is the right one of the two center blocks, and the cutting point is on it.

$$B(B_1, B_2, \dots, B_{\frac{m}{2}+1}, B_{\frac{m}{2}+2}, \dots, B_m)$$

$$\widehat{B.m}(\overbrace{B_{\frac{m}{2}+1}B_{\frac{m}{2}+2}, \dots, B_{m-1}B_m, B_mB_1, \dots, B_{\frac{m}{2}}B_{\frac{m}{2}+1}}) \dots\dots\dots\text{Formula(2)}$$

The shifted message has moved about  $8m$  words.ie.,each the block is shifted for about  $8m$  words from it's corresponding one.

If  $P$  and  $S$  are all multi-block massages,we'll get the same result.(see appendix1)

There's another question:What about pre-computing the regrouped blocks(not the single shifted blocks and the original blocks)?

It seems that the pre-computed results can be useful if the regrouped blocks have been pre-computed . If a "diamond structure" is made up of the regrouped blocks,can the pre-computing results be used again?

If pre-compute the regrouped blocks, The original message will act as the shift version of the shifted message,and the original blocks act as the shifted ones,therefore ,just like the previous analysis ,that idea which pre-computing the regrouped blocks can't be realized.

Then,what about pre-computing the regrouped blocks and the original blocks together?

We'll explain by giving an example :

A two-block message  $AB$ ,

Block  $A$     Block  $B$

It'corresponding shifted blocks are :

$$\widehat{BA} \quad \widehat{AB}$$

Pre-compute them by binding(e.g.,binding a pair of blocks,  $A$  and  $\widehat{BA}$  ).

$$CV_1 = f_1(IV, A) + f_2(IV, \widehat{BA}).$$

Assume the two-block message  $AB$ (which it's  $m_{AB} = 2$ ) is cascaded with an other message  $C_x$ (which it's  $m_c$  blocks) , there become a new message  $C_xAB$  with  $m(m = m_{AB} + m_c)$ blocks.then,there always  $m > m_{AB}$  ,the positions of the shifted blocks have to move again,the pre-computed result of the binding blocks, a pair of  $A$  and  $\widehat{BA}$  is no use.

In fact, the blocks themself have been changed also ,there is no block  $\widehat{BA}$  anymore.

E.g.,let  $C_x$  be a sing block,ie., $m_c = 1$ . $C_x$  is the first block,the original message is  $C_xAB$ ,ie.,Block  $C_x$ ,Block  $B$  and Block  $A$ :

$$C_x \quad A \quad B$$

the corresponding shifted blocks are( $m = 3$ ,it's an odd number,where Block  $A$  is the cutting point.) :

$\widehat{AB}, \widehat{BC_x}, \widehat{C_xA}$ .

Now, the corresponding block of  $A$  is  $\widehat{BC_x}$ , this pair of blocks Block  $A$  and  $\widehat{BC_x}$  are different from the previous binding blocks,  $A$  and  $\widehat{BA}$ .

$CV'_1 = f_1(IV, A) + f_2(IV, \widehat{BC_x})$ , obviously,  $CV'_1 \neq CV_1$

And then, there produced the new regrouped blocks:  $\widehat{BC_x}$  and  $\widehat{C_xA}$ , which are different from the regrouped blocks of  $AB$ .

So we can't use the known result of Pre-computing a pair of binding blocks.

Synchronously, if two single blocks are cascaded to be a two-block message, each block contains 16 words (64 bit-word), there are  $64 \times 16 \times 2 = 2048$  bits, i.e., there are about  $2^{2048}$  kinds two-block messages.

Obviously, there are about  $(2^{1024})^3$  kinds of 3-block message, and  $(2^{1024})^4$  for 4-block message, ... therefore, that can be hardly realized to build a so called "diamond structure" for herding attack.

## 2.4 Second Preimage Attacks In Shift Mode

For *Second Preimage Attacks on Dithered Hash Functions* of Andreeva et al [4], their basic technique relies on the diamond from the herding attack [6], if the diamond structure of herding is too hard to build, the attack is defeated.

The second preimage attack of Dean means [7] is, to insert a block (or blocks) at so called a fixed point  $i$ th block, then make a preassigned output  $CV_i$  equal to the input  $CV_i$ .

Let's see Second Preimage Attacks again by "shifting whole message".

There are three types messages (and the corresponding blocks), first is the original message, second is the single shifted message for precomputing, third is the regrouped message after cascading.

We assume two messages  $A_x$  and  $B_y$ .  $A_x$  contains  $m_1$  blocks and  $B_y$  contains  $m_2$  (For simplicity, let's set  $m_2 = 3$ ) blocks.  $m_1 > m_2$ , and both of them are odd numbers,

We will insert  $B_y$  into  $A_x$  at the point (the  $i$ th block of  $A_x$ ). Might as well set  $1 \leq i < \frac{m_1+m_2}{2} - 3$ .

The single original message  $A_x$  is:

$A_x(A_1, \dots, A_{i-1}, \dots, A_{\frac{m_1+1}{2}}, \dots, A_{m_1})$

(block  $A_{\frac{m_1+1}{2}}$  is the cutting point for the single message  $A_x$ .)

For precomputing, The shifted message of  $A_x$  is (According to Formula (1)):

$\widehat{A_x.m_1}(\widehat{A_{\frac{m_1+1}{2}} A_{\frac{m_1+3}{2}}}, \dots, \widehat{A_{m_1-1} A_{m_1}}, \widehat{A_{m_1} A_1}, \dots, \widehat{A_{\frac{2i-m_1-1}{2}} A_{\frac{2i-m_1+1}{2}}}, \dots, \widehat{A_{\frac{m_1-1}{2}} A_{\frac{m_1+1}{2}}})$

The first  $i$  blocks of  $\overbrace{A_x.m_1}$ :

$$\left( \overbrace{A_{\frac{m_1+1}{2}} A_{\frac{m_1+3}{2}}}, \dots, \overbrace{A_{m_1-1} A_{m_1}}, \overbrace{A_{m_1} A_1}, \dots, \overbrace{A_{\frac{2i-m_1-1}{2}} A_{\frac{2i-m_1+1}{2}}} \right)$$

The single original message  $B_y$  is:

$$B_y(B_1, B_2, B_3)$$

For precomputing, the single shifted message of  $B_y$  is (According to Formula(1)):

$$\overbrace{B_y.3}(B_2 B_3, B_3 B_1, B_1 B_2)$$

Precomputation of the single shifted message:

Compute the first  $i$  blocks of  $\overbrace{A_x.m_1}$ :

$$f(IV, \left( \overbrace{A_{\frac{m_1+1}{2}} A_{\frac{m_1+3}{2}}}, \dots, \overbrace{A_{m_1-1} A_{m_1}}, \overbrace{A_{m_1} A_1}, \dots, \overbrace{A_{\frac{2i-m_1-1}{2}} A_{\frac{2i-m_1+1}{2}}} \right)) = CV_i$$

$$\text{Assume that: } f(CV_i, \overbrace{B_y.3}) = CV_i \text{ ie., } f(CV_i, \left( \overbrace{B_2 B_3}, \overbrace{B_3 B_1}, \overbrace{B_1 B_2} \right)) = CV_i$$

Cascading:

Insert  $B_y$  into  $A_x$  at the point  $A_i$ , then, there become a cascaded message.

$A_x - B_y$  denotes the original cascaded message. such that:

$$A_x - B_y(A_1, \dots, A_i, B_1, B_2, B_3, A_{i+1}, \dots, A_{\frac{m_1+1}{2}}, A_{\frac{m_1+3}{2}}, A_{\frac{m_1+5}{2}}, \dots, A_{m_1})$$

The original message  $A_x - B_y$  contains  $m$  blocks, which

$m = m_1 + m_2 = m_1 + 3$ , and  $m$  is an even number.

$$\textbf{Formula(2): } \overbrace{B.m}(B_{\frac{m}{2}+1} B_{\frac{m}{2}+2}, \dots, B_{m-1} B_m, B_m B_1, \dots, B_{\frac{m}{2}} B_{\frac{m}{2}+1})$$

For message  $A_x - B_y$ , Block  $A_{\frac{m}{2}+1}$  is the cutting point.

$$(A_{\frac{m}{2}+1} = A_{\frac{m_1+m_2}{2}+1} = A_{\frac{m_1+3}{2}+1} = A_{\frac{m_1+5}{2}})$$

We get the cascaded shift message  $\overbrace{A_x - B_y}$ :

$$\left( \overbrace{A_{\frac{m_1+5}{2}} A_{\frac{m_1+7}{2}}}, \dots, \overbrace{A_{m_1-1} A_{m_1}}, \overbrace{A_{m_1} A_1}, \dots, \overbrace{A_{i-1} A_i}, \overbrace{A_i B_1}, \overbrace{B_1 B_2}, \overbrace{B_3 A_{i+1}}, \dots, \overbrace{A_{\frac{m_1+3}{2}} A_{\frac{m_1+5}{2}}} \right)$$

(Of course, we can write the first  $i$  regrouped blocks :

$$\left( \overbrace{A_{\frac{m_1+5}{2}} A_{\frac{m_1+7}{2}}}, \dots, \overbrace{A_{m_1-1} A_{m_1}}, \overbrace{A_{m_1} A_1}, \dots, \overbrace{A_{\frac{2i-m_1+3}{2}} A_{\frac{2i-m_1+5}{2}}} \right)$$

There are  $t_1$  blocks from  $\overbrace{A_{\frac{m_1+5}{2}} A_{\frac{m_1+7}{2}}}$  to  $\overbrace{A_{m_1-1} A_{m_1}}$

$$(t_1 = m_1 - \frac{m_1+7}{2} + 1 = \frac{m_1-5}{2});$$

and there are  $t_2$  blocks from  $\overbrace{A_{m_1} A_1}$  to  $\overbrace{A_{\frac{2i-m_1+3}{2}} A_{\frac{2i-m_1+5}{2}}}$ ,

$$(t_2 = \frac{2i-m_1+5}{2} - 1 + 1 = i - \frac{m_1-5}{2})$$

so,  $t_1 + t_2 = i$

and the followed 3 regrouped blocks are:

$$\left( \overbrace{A_{\frac{2i-m_1+5}{2}} A_{\frac{2i-m_1+7}{2}}}, \overbrace{A_{\frac{2i-m_1+7}{2}} A_{\frac{2i-m_1+9}{2}}}, \overbrace{A_{\frac{2i-m_1+9}{2}} A_{\frac{2i-m_1+11}{2}}} \right)$$

Compare the first  $i$  regrouped blocks with the first  $i$  single shifted blocks, they are different.

Obviously, Compute the first  $i$  regrouped blocks and the first  $i$  single shifted blocks, their output are not equal, i.e., the output of the  $i$ th cascaded block isn't equal to  $CV_i$ .

That means, for the followed regrouped blocks, the input is not  $CV_i$ , synchronously, the 3 regrouped blocks  $\overbrace{A_i B_1}, \overbrace{B_1 B_2}$ , and  $\overbrace{B_{m_2} A_{i+1}}$  are different from  $\overbrace{B_y.3}$ , so, there can't compute that  $f(CV_i, \overbrace{B_y.3}) = CV_i$ .

If set  $m_2$  and  $i$  be other values, we can get the same result. There always be  $m > m_1$  and  $m > m_2$ , and simply it's shift parameter  $s > s_1$  and  $s > s_2$ . So, once the message  $B_y$  is inserted into  $A_x$ , the pre-computed blocks of  $A_x$  or  $B_y$  have to shift again, i.e., each the position of the blocks has been changed. therefore, there isn't a point so called "fixed point", and there's no input  $CV_i$  for  $B_y$ .

On the other way, the pre-computed blocks of  $B_y$  have also been changed.

There'll always be the new regrouped blocks  $\overbrace{A_i B_1}$  and  $\overbrace{B_{m_2} A_{i+1}}$  for corresponding blocks of  $B_y$ .

In the cascaded message, the chaining value input  $CV_i$ , the positions of blocks and even each the blocks of  $A_x$  are all changed, we can't get a chaining value  $CV_i$  at the point  $i$ th block, and there's no  $\overbrace{B_y.3}$  can be computed such that  $f(CV_i, \overbrace{B_y.3}) = CV_i$ , so, the attack is invalid.

## 2.5 Some Conditions

What about the condition that the shifted message is same as the original one?

We give an example message  $A, m = 1$ , i.e., that a single original block

$A(x_0, x_1, \dots, x_6, x_7, \dots, x_{15})$  is same as it's shifted block

$\overbrace{A}(x_9, x_{10}, \dots, x_{15}, x_0, \dots, x_8)$ . This means, their corresponding elements are equal:

$$x_0 = x_9, x_1 = x_{10}, \dots, x_6 = x_{15}, x_7 = x_0, \dots, x_{15} = x_8$$

From these 16 equations, we can get:

$$x_0 = x_1 = x_2 = \dots = x_{15}$$

It means that the message is an especial one, each of the 16 words is the same and fixed one.

By similar,we can get the similar results for a multi-blocks-message(see appendix2).

It doesn't make different result from the previous analysis if two different special messages are cascaded.

The followed is a detailed proposal.

### 3 A Detailed Proposal

First,for pretreatment ,we get two messages.

For a message  $x$ ,after padding and appending length,it's length is  $16m \times 64$  bits, the message is formatted as  $16m$  64-bit words  $:x_0, x_1, \dots, x_i, \dots, x_{16m-1}$ , ie.,the message is made up of  $m$  blocks( $B_1, B_2, \dots, B_m$ ) and each the block contains 16 64-bit words.we set a shift parameter  $s = 8m + 1$ , if  $m$  is a odd number; and set  $s = 8m + 7$  if  $m$  is a even number.

1 The original message is:  $x_0, x_1, \dots, x_{8m}, x_{8m+1}, \dots, x_{8m+6}, x_{8m+7}, \dots, x_{16m-1}$

2 the shifted message is:

$x_{8m+1}, \dots, x_{16m-1}, x_0, x_1, \dots, x_{8m}$  ( $m$  is an odd number);

$x_{8m+7}, \dots, x_{16m-1}, x_0, x_1, \dots, x_{8m+6}$  (if  $m$  is an even number)

The original message can be written as  $:B_1, B_2, \dots, B_i, \dots, B_m$

And the shift message can be written as: $B_{S1}, B_{S2}, \dots, B_{Si}, \dots, B_{Sm}$ .

Second,set two parallel compression functions  $f_1$  and  $f_2$  ,which are similar compression functions outputting chaining-value with same length:

$f_1$  outputs  $k$ (assume  $k \geq 8$ ) 64-bit values of  $CV_{O_i}$  and  $f_2$  outputs  $k$  64-bit values of  $CV_{S_i}$ .  $f_1$  acts the original blocks ,  $f_2$  acts the regrouped blocks,for message  $x$ ,the hash function  $H(x)$ , such that

for  $1 \leq i \leq m$ ,

$CV_0 = IV$

$CV_i = CV_{O_i} + CV_{S_i}$  where "+" is  $2^{64}$  modulo addition.

$CV_{O_i} = f_1(CV_{i-1}, B_i)$  ;  $CV_{S_i} = f_2(CV_{i-1}, B_{S_i})$

$H(x) = CV_m$

Where  $CV_{O_i}$  is the  $i$ th output of the original block  $B_i$ ;

$CV_{S_i}$  is the  $i$ th output of the regrouped block  $B_{S_i}$ .

This is a simple proposal,and we can get a stronger vision.

Based on the previous proposal,we add a step so called "Second Hash".

Make the last regrouped block  $B_{Sm}$  a extra-block  $B_{xta}$ :

Add the chaining-value  $CV_{O_m}$  and  $CV_{S_m}$  into the message of block  $B_{Sm}$ .

$B_{Sm}$  is written as:  $B_{Sm}(u_0, u_1, \dots, u_{15})$  ;  
 the output of  $f_1$  is written as:  $CV_{Om}(V_{O1}, V_{O2}, \dots, V_{Ok})$ ;  
 the output of  $f_2$  is written as:  $CV_{Sm}(V_{S1}, V_{S2}, \dots, V_{Sk})$  ,  
 then get 16 variables from the each first 8 variables of  $CV_{Om}$  and  $CV_{Sm}$ , such  
 that:

$(V_{O1}, V_{O2}, \dots, V_{O8}, V_{S1}, V_{S2}, \dots, V_{S8})$  and compute:  
 $u_0 = u_0 + V_{O1}, u_1 = u_1 + V_{O2}, \dots, u_7 = u_7 + V_{O8}$ ;  
 $u_8 = u_8 + V_{S1}, u_9 = u_9 + V_{S2}, \dots, u_{15} = u_{15} + V_{S8}$

Compute the extra block  $B_{xta}$  by  $f_1$  and  $f_2$ :  
 $CV_O = f_1(CV_m, B_{xta})$   
 $CV_S = f_2(IV, B_{xta})$   
 $H(x) = CV_O + CV_S$

We may select a new strong-avalanche hash function to work as the two parallel  
 compression functions  $f_1$  and  $f_2$ , and to resist the differential attacks on collision  
 resistance.

## 4 summary

That the main weakness of a iterating hash function is it can be modular-  
 ized. The attackers make use of this and develop various attacks.

Our purpose is how to break the modularization. Based on the two parallel  
 modes which called "original" and "shift", we built the proposal, and the "Sec-  
 ond Hash" is helpful. It seems that the iterating hash functions should be reval-  
 ued, even though that the candidates of SH3 are advanced, the task of building a  
 real secure hash function isn't finished.

## 6 Appendix

### 6.1 Appendix1

#### The Herding Attack of Multi-block Massages $P$ And $S$ In Shift Mode

$P$  and  $S$  are both multi-block massages.  $P$  contains  $m_1$ (Assume  $m_1$  is an odd number) blocks,such that

$$P(P_1, P_2, \dots, P_{\frac{m_1+1}{2}}, \dots, P_{m_1}).$$

And  $S$  contains  $m_2$ (Assume  $m_2$  is an odd number also,and  $m_1 > m_2$ ) blocks,  
 $S(S_1, S_2, \dots, S_{\frac{m_2+1}{2}}, \dots, S_{m_2}).$

Then ,for pre-computing,the single shifted message are( $m_1, m_2$  are odd numbers,according to Formula(1)):

$$\begin{aligned} & \overbrace{P.m_1} ( \overbrace{P_{\frac{m_1+1}{2}} P_{\frac{m_1+3}{2}}}, \dots, \overbrace{P_{m_1-1} P_{m_1}}, \overbrace{P_{m_1} P_1}, \dots, \overbrace{P_{\frac{m_1-1}{2}} P_{\frac{m_1+1}{2}}} ) \\ & \overbrace{S.m_2} ( \overbrace{S_{\frac{m_2+1}{2}} S_{\frac{m_2+3}{2}}}, \dots, \overbrace{S_{m_2-1} S_{m_2}}, \overbrace{S_{m_2} S_1}, \dots, \overbrace{S_{\frac{m_2-1}{2}} S_{\frac{m_2+1}{2}}} ) \end{aligned}$$

Assume that: $f(IV, \overbrace{P.m_1}) = z_1, f(z_1, \overbrace{S.m_2}) = h.$

We'll see ,whether"  $f(IV, P - S) = h$  " can be gotten.

$P, S$  are cascaded to be a  $m$ -block massage  $P - S$

$$P - S(P_1, P_2, \dots, P_{\frac{m}{2}+1}, \dots, P_{m_1}, S_1, S_2, \dots, S_{m_2}).$$

$m = m_1 + m_2, m$  is an even number,according to Formula(2), $P_{\frac{m}{2}+1}$  is the cutting point,the shifted message of  $P - S$  is:

$$\begin{aligned} & ( \overbrace{P_{\frac{m}{2}+1} P_{\frac{m}{2}+2}}, \dots, \overbrace{P_{m_1-1} P_{m_1}}, \overbrace{P_{m_1} S_1}, \dots, \overbrace{S_{m_2-1} S_{m_2}}, \overbrace{S_{m_2} P_1}, \overbrace{P_2 P_3}, \dots, \overbrace{P_{\frac{m_1-m_2}{2}} P_{\frac{m_1-m_2}{2}+1}}, \\ & \overbrace{P_{\frac{m_1-m_2}{2}+1} P_{\frac{m_1-m_2}{2}+2}}, \dots, \overbrace{P_{\frac{m}{2}} P_{\frac{m}{2}+1}} ) \end{aligned}$$

Let  $P'$  denotes the message group of the first  $m_1$  shifted blocks,  $P'$ :

$$( \overbrace{P_{\frac{m}{2}+1} P_{\frac{m}{2}+2}}, \dots, \overbrace{P_{m_1-1} P_{m_1}}, \overbrace{P_{m_1} S_1}, \dots, \overbrace{S_{m_2-1} S_{m_2}}, \overbrace{S_{m_2} P_1}, \overbrace{P_2 P_3}, \dots, \overbrace{P_{\frac{m_1-m_2}{2}} P_{\frac{m_1-m_2}{2}+1}} )$$

Obviously it's different from  $\overbrace{P.m_1}$ ,so,we can't get  $f(IV, P') = z_1.$

Let  $S'$  denotes the message group of the left  $m_2$  blocks, $S'$  :

$$( \overbrace{P_{\frac{m_1-m_2}{2}+1} P_{\frac{m_1-m_2}{2}+2}}, \dots, \overbrace{P_{\frac{m}{2}} P_{\frac{m}{2}+1}} )$$

It's also different from  $\overbrace{S.m_2}$ ,we can't get  $f(z_1, S') = h.$

Therefore,we can't get  $f(IV, P - S) = h.$

## 6.2 Appendix2

The Equal Condition of The Two Versions From A Multi-blocks-message

Assume  $m$  is an odd number,  $m \geq 1$ , A message (where "||" is the center, "||" is the cutting point):

$$x_0, x_1, x_2, \dots, x_{8m-2}, x_{8m-1}, ||x_{8m}|, x_{8m+1}, x_{8m+2}, x_{8m+3}, \dots, x_{16m-1}.$$

then,  $s = 8m + 1$ , the shifted message is:

$$x_{8m+1}, x_{8m+2}, x_{8m+3}, \dots, x_{16m-1}, x_0, ||x_1, x_2, \dots, x_{8m-2}, x_{8m-1}, x_{8m}$$

Assume the two versions message are equal, then the corresponding words are equal:

from the left to the right ,contrast the words of the two versions in turn:

the left  $x_0 = x_{8m+1}$  ;the right  $x_{8m+1} = x_2$

the left  $x_2 = x_{8m+3}$  ;the right  $x_{8m+3} = x_4$

...

we get:

$$x_0 = x_{8m+1} = x_2 = x_{8m+3} = x_4 = \dots = x_{8m-2} = x_{16m-1} = x_{8m}; x_{8m} = x_1 = x_{8m+2} = x_3 = \dots = x_{16m-2} = x_{8m-1} = x_0$$

i.e., all the even words are equal:  $x_0 = x_2 = \dots x_{8m} = \dots x_{16m-2}$

we can also get  $x_1 = x_3 = \dots x_{8m-1} = \dots x_{16m-1}$ , i.e. all the odd words are equal.

since  $x_1 = x_{8m+2}$ , the odds equal to the evens. then, all the words are equal:

$$x_0 = x_1 = x_2 = \dots = x_{16m-1}$$

If Assume  $m$  is an even number ,we can get the same result.

If the two versions messages (the original message and the shifted message) are the same ,then the each word of the message is the same.
