#### Abstract

We present a computationally sound first-order system for security-analysis of protocols that places secrecy of nonces and keys in its center. Even trace properties such as agreement and authentication are proven via proving a non-trace property, namely, secrecy first with an inductive method. This results a very powerful system, the working of which we illustrate on the agreement and authentication proofs for the Needham-Schroeder-Lowe publickey and the amended Needham-Schroeder shared-key protocols in case of unlimited sessions. Unlike other available formal verification techniques, computational soundness of our approach does not require any idealizations about parsing of bitstrings or unnecessary tagging. In particular, we have control over detecting and eliminating the possibility of type-flaw attacks.

Keywords. cryptographic protocols, formal methods, first order logic, computational semantics

## 1. Introduction

In the first-order logic framework, protocol correctness is analyzed by defining a syntax with adding some axioms (expressing security properties etc.) to the usual axioms and inference rules of first order logic and then proving some security property directly. This is in contrast with other methods that eliminate the possibility of successful formal (Dolev-Yao) adversaries. In those latter other approaches, for computational soundness, it is necessary to show that the lack of successful formal adversaries lead to a lack of successful computational ones. However, no-one has managed to do this satisfactorily, as such a theorem always requires
to significantly limit the capabilities of computational adversaries as to this date there is no complete formal description of computational adversarial capabilities. In contrast, a logical method, like the one we present, does not require the notion of formal adversary. The link to the computational world is done by assigning a class of computational structures to the syntax, proving that the axioms and inference rules hold (computationally) there, and so the elements of this class can work as computational models of the syntax. This way, a property provable in the syntax must be true in any such computational model.

In earlier logical methods as [13, 10, 2], trace properties were not proven via secrecy of encryption, but, instead, via rather limited aspects of the secrecy of encryption. Namely, in case of public key, via axioms saying that if something was encrypted honestly with an honest agent's public key, and this thing later appeared in a different form, then it had to go through the agent whose key was used for the encryption. Hence, the strong notion of computational secrecy was limited to this trace aspect of it. Instead, we now consider the following predicates:

$$
\operatorname{Sec}_{\tau}\left(\left\langle A_{1}, \ldots, A_{n}\right\rangle, t, N\right)
$$

and

$$
\operatorname{KeySec}_{\tau}\left(\left\langle A_{1}, \ldots, A_{n}\right\rangle, t, K\right)
$$

The meaning of the first is the following: agents not included in $A_{1}, \ldots, A_{n}$, and also the adversary, based on their views of the protocol until time $\tau$, and providing them $t$, they cannot differentiate the nonce $N$ from another nonce $N^{\prime}$ that was generated independently of the protocol. The meaning of the second one is that the key $K$ can be used for secure encryption until $\tau$ by any of $A_{1}, \ldots, A_{n}$ even if $t$ is revealed to the public.

The rough idea of protocol proof is then to derive from a set of axioms that if $A_{1}, \ldots, A_{n}$ are honest participants of the protocol carrying out only their protocol roles, then for each of their send actions,

$$
[K e y] S e c_{\tau}\left(\left\langle A_{1}, \ldots, A_{n}\right\rangle, N / K\right) \wedge A_{j} \operatorname{sends} s_{\tau}^{i} t
$$

implies

$$
[K e y] \operatorname{Sec}_{\tau}\left(\left\langle A_{1}, \ldots, A_{n}\right\rangle, t, N / K\right) \wedge A_{j} \operatorname{sends}_{\tau}^{i} t
$$

where $A_{j} \operatorname{sends}{ }_{\tau}^{i} t$ means that $A_{j}$ sends $t$ in its session $i$ at time $\tau$ and $[K e y] S e c_{\tau}$ is either Sec or KeySec, $N / K$ is a nonce or key. Note that $t$ in the send action and inside the secrecy predicate are the same. This means that if $N$ (or $K$ ) was uncorrupted until sending $t$, then the send action will not corrupt $N$ (or $K$ ), as the secrecy of it holds even if $t$ is revealed. The core part of the protocol proof is to build $t$ up inside the security predicate from its parts (e.g. $t=\left\{N_{1}, A\right\}_{A}^{r}$ ). This is proven for every send action of every honest agent, meaning that $N$ and $K$ are never corrupted, because no send action corrupts them. For the commitment problem, the formulation is a little different, proving that $N$ or $K$ are not corrupted before a certain action happens.

Once this way the uncorrupted nature of nonces and keys are proven, the agreement and authentication properties can be proven, as when uncorrupted nonces are received encrypted, they must have been sent by agents with respect of whom the nonce is secret.

We also present a theorem, which says that for proving a certain class of formulas (agreement and authentication are such) the proof can be carried out in a simpler theory, which is not sound, but the result of the proof is still sound.

This system hence has a number of advantages:

- It is a relatively simple, but very general system that can provide computationally sound proofs of secrecy, authentication, agreement for unlimited sessions.
- Does not require any idealizations about parsing bitstrings or tagging for computational soundness.
- Parsing properties can be conveniently adjusted in the term axioms. As a result, type-flaw errors in the form of axioms missing for a proof can be detected, and the set of axioms can be modified depending on what kind of type-flaw errors we want to allow.
- As far as we know, for the first time without idealized parsing, provides computationally sound agreement, authentication and secrecy proofs for NSL and symmetric NS protocols (with IND-CCA public and IND-CCA as well as for given plaintext unforgeable public key encryptions).
- As far as we know, for the first time able to deal with the commitment problem.
- The system implicitly also takes care of key cycles. The axioms are such, that in case of key cycles, it is not possible to prove KeySec for those keys, hence encryptions with them cannot be used for proving secrecy or authentication.

Related Work. Formal methods emerged from the seminal work of Dolev and Yao [12]. The main approaches have been on one hand logical such as in BAN logic [4], Protocol Composition Logic (PCL) [13], on the other hand tracebased, such as strand spaces [14] or MSR [6]. Accordingly, linking formal and computational security in an active setting has two major different approaches: a logical with no formal execution as in [11, 2], or deriving computational security from the non-existence of formal attacks [1, 9, 8]. Recently Roy et al. considered inductive derivation of security in computational setting in [18].

We would like to thank Paulo Mateus and Hubert Comon-Lundh for many inspiring discussions.

## 2. Basic Protocol Logic 2.0 Syntax

For the intuitive meaning of syntactic objects, let us clarify the following: A computational execution of a protocol is stochastic, with a sequence of coin tosses defining a tree of coin tosses for each fixed security parameter. We will call one branch, when all coins are fixed, a branch of coin tosses. The set of all branches is the underlying probability space.

### 2.1. Language

Sorts. Our language is order-sorted, with the following sort structure:

We require countably infinite variables of each sort. timesection has three constant, $\mathbf{0}, \mathbf{1}$ and $\infty$, while event has one: D. We also introduce the error constant $\perp$ of sort bitstring.

The intuitive meanings of the sorts are the following:

- hname is the sort of the names of honest (uncorrupted) principals (we don't model dynamic corruption here). They as well as their long-term keys have to be fixed before the run of the protocol.
- name represent principals in general. They don't have to be fixed before the run of the protocol. Their keys
do not have to be correctly generated. Any principal's name may have non-trivial distributions. They are known to the adversary.
- hnonce means honest nonces, which are honestly generated by some principal, with the correct distribution and independently of everything that happened before.
- hkey means honest shared keys, which are honestly generated by some principal with the correct distribution, independently of everything happening before.
- hseed represent honestly generated random seed of encryptions.
- sessionid represents the session id's that keep track of the principals' sessions. These are internal records.
- bitstring represents unparsed messages. Computationally, a sequence (in the security parameter) of bitstring valued random variables (functions) over a nonnegligible part of the tree of coin tosses.
- bittree represents parsed messages. That is, labeled ordered trees such that the leafs are labelled by items of sort bitstring, while the internal nodes are labelled by one of the function symbols Pair, LPKEnc, LSKEnc, SKEnc (see below). The child nodes have to agree with the arities of the function symbols.
- timesection represents a moment of the execution. Computationally, it assigns a natural number to every branch of coin tosses, so it is a sequence of random variables.
- event represents probabilistic events. Computationally, non-negligible sequences (in the security parameter) of sets of branches of coin tosses.

The computational interpretations of the sorts in Section A. 2 should clarify their meaning further.

Remark 2.1. The sort event is only needed for soundness. In the authentication and agreement proofs, the proofs will be correct even if we delete this sort from the axioms. However, in that case, the axioms will not be sound any more. See Theorem 2.10.

We will denote variables according the Table 1.
Function Symbols and Terms. We introduce the following function symbols with short notation. Please note from now that the intuitive meaning of terms here is different from what is common in computational semantics. $\{t\}_{Q}^{s}$ is not a ciphertext, but a parsed object. $\overline{\{t\}_{Q}^{s}}$ is the ciphertext.

- Pairing:

$$
\begin{aligned}
& \text { Pair }: \text { bittree } \times \text { bittree } \rightarrow \text { bittree } \\
& \left\langle t, t^{\prime}\right\rangle \equiv \operatorname{Pair}\left(t, t^{\prime}\right) \\
& \left\langle t_{1}, t_{2}, t_{3} \ldots, t_{j}\right\rangle \equiv\left\langle\ldots\left\langle\left\langle t_{1}, t_{2}\right\rangle, t_{3}\right\rangle, \ldots, t_{j}\right\rangle
\end{aligned}
$$

| hseed | $r, r^{\prime}, \ldots, r_{1}, r_{2}$ |
| :---: | :---: |
| hname | $A, B, \ldots, A_{1}, A_{2}, \ldots$ |
| name | $Q, Q^{\prime} \ldots, Q_{1}, Q_{2}, \ldots$ |
| hnonce | $N, N^{\prime}, \ldots, N_{1}, N_{2}, \ldots$ |
| hkey | $K, K^{\prime}, \ldots, K_{1}, K_{2}, \ldots$ |
| nonce or hkey | $\nu, \nu^{\prime}, \ldots, \nu_{1}, \nu_{2}, \ldots$ |
| sessionid | $i, i^{\prime}, \ldots, i_{1}, i_{2}, \ldots$ |
|  | $s, s^{\prime}, \ldots, s_{1}, s_{2}, \ldots$ |
| bitstring | $n, n^{\prime}, \ldots, n_{1}, n_{2}, \ldots$ |
|  | $k, k^{\prime}, \ldots, k_{1}, k_{2}, \ldots$ |
|  | $m, m^{\prime}, \ldots, m_{1}, m_{2}, \ldots$ |
| bittree | $t, t^{\prime}, \ldots, t_{1}, t_{2}, \ldots$ |
|  | $u, u^{\prime}, \ldots, u_{1}, u_{2}, \ldots$ |
| timesection | $\tau, \tau^{\prime}, \ldots, \tau_{1}, \tau_{2}, \ldots$ |
| event | $\Delta, \Delta^{\prime}, \ldots, \Delta_{1}, \Delta_{2}, \ldots$ |
| any variable | $v, v^{\prime}, \ldots, v_{1}, v_{2}, \ldots$ |

Table 1. Convention of variables

- Encryption with (long term) public key (of $Q$ ):

$$
\begin{aligned}
& \text { LPKEnc : name } \times \text { bittree } \times \text { bitstring } \rightarrow \text { bittree } \\
& \{t\}_{Q}^{s} \equiv \operatorname{LPKEnc}(Q, t, s)
\end{aligned}
$$

- Encryption with long term shared key (of $Q$ and $Q^{\prime}$ ):

LSKEnc: name $\times$ name $\times$ bittree $\times$ bitstring $\rightarrow$ bittree $\{t\}_{Q Q^{\prime}}^{s} \equiv \operatorname{LSKEnc}\left(Q, Q^{\prime}, t, s\right)$

- Encryption with shared session key:

SKEnc: bitstring $\times$ bittree $\times$ bitstring $\rightarrow$ bittree $\{t\}_{k}^{s} \equiv \operatorname{SKEnc}(k, t, s)$

- Computation of the encryptions and pairings in a bittree:

$$
\begin{aligned}
& \text { Evaluate }: \text { bittree } \rightarrow \text { bitstring } \\
& \bar{t} \equiv \text { Evaluate }(t)
\end{aligned}
$$

Message terms (we refer to them as "terms" in short, although strictly speaking $\tau$ and $\Delta$ are also terms as usual in first order logic) are defined as:

$$
T::=t|\bar{T}|\langle T, T\rangle\left|\{T\}_{Q}^{s}\right|\{T\}_{Q Q^{\prime}}^{s} \mid\{T\}_{k}^{s}
$$

All message terms are of sort bittree. We will sometimes use the meta-symbols $T, T^{\prime} \ldots$ to denote compound terms. We think of a term as the following tree. The expression under the overline is not parsed as $\bar{T}$ is a bitstring.
Predicates. We introduce a number of predicate symbols, the intuitive meanings of which require some explanation.

- $t=t^{\prime}, \tau=\tau^{\prime}, \Delta=\Delta^{\prime}$

Equality up to negligible probability. For $t$ and $t^{\prime}$ trees,

Figure 1. Parsing tree
they must have the same tree structure with the same function symbol labels, and equal labels on the leafs, except for the encryption seeds.

- $t=\left.t^{\prime}\right|_{\Delta}, \tau=\left.\tau^{\prime}\right|_{\Delta}, \Delta^{\prime}=\left.\Delta^{\prime \prime}\right|_{\Delta}$

Ternary predicates. Equality up to negligibility restricted to the event (subset) $\Delta$. We will also use the notation $t=\Delta t^{\prime}, \tau=\Delta \tau^{\prime}, \Delta^{\prime}=\Delta \Delta^{\prime \prime}$. Predicate $={ }_{\mathrm{D}}$ is the same as $=, \mathrm{so}=$ is a special case of $=\Delta$.

- $\left.t \sqsubseteq t^{\prime}\right|_{\Delta}$

Ternary predicate. Meaning that the tree of $t$ equals on $\Delta$ (in the above sense) a subtree of $t^{\prime}$, and is not a leaf corresponding to the random seed or the key of an encryption. We will also use $\sqsubseteq \Delta$. We also write $\sqsubseteq$ for $\sqsubseteq_{\text {D. }}$. See examples below.

- $\tau<\left.\tau^{\prime}\right|_{\Delta}$

Ternary. Time section $\tau$ is strictly earlier than $\tau^{\prime}$ of every branch of $\Delta$ (up to negligible probability).

- $\left.\Delta^{\prime} \subseteq \Delta^{\prime \prime}\right|_{\Delta}$

The $\Delta^{\prime} \cap \Delta$ is a subset of $\Delta^{\prime \prime} \cap \Delta$ (up to negligible probability).

- $Q$ generates $\left.{ }_{\tau}^{i} N\right|_{\Delta}$

Principal $Q$ generates a fresh nonce $N$ at time section $\tau$ in session he labels $i$ on all (up to negligible probability) branches in $\Delta$. Such $N$ will be required to have the correct distribution of nonces in $\Delta$ and be independent of what happened until the generation.

- $Q$ receives $\left._{\tau}^{i} t\right|_{\Delta}$

On all branches of $\Delta$, principal $Q$ receives a message in session $i$ at time $\tau$ represented by $t$ and parses it to reveal the subterms in $t$. $Q$ does exactly as much parsing as shown by $t$ (except for randomnesses in the upper index of encryption which is not parsed). That is, $Q$ receives $_{\tau}^{i}\{A, m, \overline{\langle N, K\rangle}\}_{Q}^{r}$ means that $Q$ received the message that as a random variable of bitstrings is $\overline{\{A, m, \overline{\langle N, K\rangle}\}_{Q}^{r}}$, and parsed it to the point of recording $A$ and $m$ and the bit string $\overline{\langle N, K\rangle}$ (again, $r$ is never parsed, and $\overline{\langle N, K\rangle}$ is not parsed either as it is not a tree, but a bit string). Note, if $Q$ is honest, it only parses using its own decryption key, so $Q$ receives ${ }_{\tau}^{i}\{A, M\}_{Q^{\prime}}^{r}$ implies $Q=Q^{\prime}$.

- $\left.Q \operatorname{sends} s_{\tau}^{i} t\right|_{\Delta}$

The meaning of this is similar to the receive action, but in the opposite direction: it means on all branches of $\Delta$, $Q$ in its session $i$ puts together $t$ from as many parts as indicated in the expression, computes $\bar{t}$ and then sends it at time $\tau$.

- $\left.\operatorname{Sec}_{\tau}\left(\left\langle A_{1}, \ldots A_{n}\right\rangle, t, \nu\right)\right|_{\Delta}$

This is called secrecy predicate. It is satisfied if principals other $A_{1}, \ldots A_{n}$ together with the adversary cannot distinguish $\nu$ from a nonce (or key respectively) generated independently of the protocol based on their view of the protocol until (not including) $\tau$ in $\Delta$, even if they are given the bitstring corresponding to $t$, that is, $\bar{t}$.

- KeySec $\left.c_{\tau}\left(\left\langle A_{1}, \ldots A_{n}\right\rangle, t, K\right)\right|_{\Delta}$

This is called key-secrecy predicate. It is satisfied if $A_{1}, \ldots A_{n}$ can safely encrypt messages using $K$ until (not including) $\tau$ in $\Delta$, even if $t$ is given to them.

If a predicate does not contain $\left.\right|_{\Delta}$, it is meant to be $\left.\right|_{\mathbf{D}}$.
Let $\tau \leq_{\Delta} \tau^{\prime} \equiv \forall \Delta^{\prime}\left(\Delta^{\prime} \subseteq \Delta \rightarrow \tau^{\prime} \nless \Delta^{\prime} \tau\right)$.
We will write $[K e y] S e c$ when we mean $S e c$ or KeySec. In case of multiple occurrence of [Key]Sec in a sentence or formula, either all are Sec or all are KeySec.

Since we do not have a special sort for lists of names, we extend $[K e y] S e c$ to $[K e y] \operatorname{Sec}(u, t, \nu)$ so that if $u$ is not a list of honest names, then the predicate gives false. We will use the notation $\vec{A} \equiv\left\langle A_{1}, \ldots A_{n}\right\rangle$.

We write $[K e y] S e c_{\tau}(\vec{A}, \nu)$ when no additional $t$ is revealed. This is the same as $[K e y] S e c_{\tau}(\vec{A}, A, \nu)$ for any $A$, as $A$ is known by everyone, so it does not reveal any additional information about $\nu$.
Example 2.2. In order to make the term structure more understandable, we include a few examples here for equality and for subterm relation: if $N \neq Q$, then $Q \nsubseteq\{N\}_{Q Q^{\prime}}^{s}$; if $N \neq s$, then $s \nsubseteq\{N\}_{Q Q^{\prime}}^{s}$; if $N \neq N^{\prime}$, then $N \nsubseteq$ $\left\{\overline{\{N\}_{B}^{r}}, N^{\prime}\right\}_{Q Q}^{s} ; \overline{\{N\}_{B}^{r}} \sqsubseteq\left\{\overline{\{N\}_{B}^{r}}, N^{\prime}\right\}_{Q Q}^{s}$. Notice, that terms under the overline are not considered subterms. Variables in the indices are not subterms either. The terms $\{N\}_{Q Q^{\prime}}^{s}$ and $\{N\}_{Q Q^{\prime}}^{s^{\prime}}$ with different random seeds may, or may not be equal. They are equal if and only if they compute to the same bit string, that is, iff $\overline{\{N\}_{Q Q^{\prime}}^{s}}=\overline{\{N\}_{Q Q^{\prime}}^{s^{\prime}}}$.
Formulas. Atomic formulas $\varphi_{0}$ are either of the forms

$$
\begin{aligned}
& \varphi_{0}::=\left.Q \operatorname{acts}_{\tau}^{i} t\right|_{\Delta}\left|[K e y] S e c_{\tau}(u, t, \nu)\right|_{\Delta} \\
& t=\Delta t^{\prime}\left|t \sqsubseteq \Delta t^{\prime}\right| \tau<\Delta \tau^{\prime} \mid \Delta^{\prime} \subseteq \Delta \Delta^{\prime \prime}
\end{aligned}
$$

Compound formulas are defined by

$$
\varphi::=\varphi_{0}|\neg \varphi| \varphi \wedge \varphi|\varphi \vee \varphi| \varphi \rightarrow \varphi|\forall v \varphi| \exists v \varphi
$$

where $v$ is any variable.
We use the meta expression $\varphi[\vec{v}]$ to indicate the list of all free variables $\vec{v}$ occurring in $\varphi$. Let $\left.\varphi\right|_{\Delta}$ be an abbreviation
defined as follows. Let $\varphi_{0}$ an atomic expression with no $\left.\right|_{\Delta}$ restriction.

```
- \(\left.\left(\left.\varphi_{0}\right|_{\Delta^{\prime}}\right)\right|_{\Delta} \equiv\left(\left.\Delta^{\prime} \subseteq \Delta \rightarrow \varphi_{0}\right|_{\Delta^{\prime}}\right) \wedge\left(\left.\Delta \subseteq \Delta^{\prime} \rightarrow \varphi_{0}\right|_{\Delta}\right)\)
- \(\left.\left.\left.\left(\varphi_{1} \wedge \varphi_{2}\right)\right|_{\Delta} \equiv \varphi_{1}\right|_{\Delta} \wedge \varphi_{2}\right|_{\Delta}\),
- \(\left.\left.\left.\left(\varphi_{1} \vee \varphi_{2}\right)\right|_{\Delta} \equiv \varphi_{1}\right|_{\Delta} \vee \varphi_{2}\right|_{\Delta}\)
- \(\left.(\neg \varphi)\right|_{\Delta} \equiv \neg\left(\left.\varphi\right|_{\Delta}\right)\)
- \(\left.\left(\exists / \forall \Delta^{\prime} \varphi\right)\right|_{\Delta} \equiv \exists / \forall \Delta^{\prime}\left(\left.\Delta^{\prime} \subseteq \Delta \rightarrow \varphi\right|_{\Delta}\right)\)
- \(\left.(\exists / \forall t / \tau \varphi)\right|_{\Delta} \equiv \exists / \forall t /\left.\tau \varphi\right|_{\Delta}\)
```

Let us introduce the notation:
$Q_{1}$ acts $_{1}^{i_{1}} t_{1} ; \ldots ; Q_{k}$ acts $_{k}^{i_{k}} t_{k} \equiv$
$\exists \tau_{1} \ldots \tau_{k}\left(\mathbf{0}<\tau_{1}<\ldots<\tau_{k} \wedge Q_{1} a^{c t s} s_{1, \tau_{1}}^{i_{1}} t_{1} \wedge \ldots \wedge Q_{k} a^{c t s}{\left.\underset{\tau_{k}}{i_{k}} t_{k}\right)}\right.$
and

$$
\begin{aligned}
& Q_{1} \text { acts }_{1, \tau_{1}}^{i_{1}} t_{1} ; \ldots ; Q_{k} \text { acts }_{k, \tau_{k}}^{i_{k}} t_{k} \equiv \\
& \mathbf{0}<\tau_{1}<\ldots<\tau_{k} \wedge Q_{1} \text { acts }_{1, \tau_{1}}^{i_{1}} t_{1} \wedge \ldots \wedge Q_{k} \text { acts }_{\tau_{k}}^{i_{k}} t_{k}
\end{aligned}
$$

These are called trace formula. Each acts ${ }_{j}$ is one of generates, sends or receives. We also use $\alpha_{1} ; \ldots ; \alpha_{k}$ (or $\vec{\alpha}$ in short) to denote the formula
 and $\vec{\beta}\left(\equiv \beta_{1} ; \ldots ; \beta_{n}\right)$, we say $\vec{\beta}$ includes $\vec{\alpha}$, denoted by

$$
\vec{\alpha} \subseteq \vec{\beta}
$$

if there is a one-to-one, increasing function $j:\{1, \ldots, m\} \rightarrow\{1, \ldots, n\}$ such that $\alpha_{k} \equiv \beta_{j(k)}$.
Roles and Protocols. Roles of principals are described by trace formulas of the form

$$
\vec{\alpha}^{A, i} \equiv A \operatorname{acts}_{1}^{i} t_{1} ; \ldots ; A \text { acts }{ }_{k}^{i} t_{k},
$$

where $t_{j}$ 's are not allowed to contain the Evaluate and Restrict function symbols. Protocols are a set of roles together with a list of values that the principals have to agree on.
Example 2.3. Roles of the Needham-Schroeder-Lowe protocol. We consider the Needham-Schroeder-Lowe public key protocol [16], whose informal description is as follows.

$$
\begin{aligned}
& \text { 1. } A \rightarrow B:\left\{N_{1}, A\right\}_{B} \\
& \text { 2. } B \rightarrow A:\left\{N_{1}, N_{2}, B\right\}_{A} \\
& \text { 3. } A \rightarrow B:\left\{N_{2}\right\}_{B}
\end{aligned}
$$

Initiator's and responder's roles of the Needham-SchroederLowe public key protocol (denoted by Init $_{\text {NSL }}$ and $\operatorname{Resp} p_{\text {NSL }}$, respectively) with session id's are described as the following formulas.

Init $_{\mathrm{NSL}}^{A}\left[A, i, Q, N_{1}, n_{2}, r_{1}, s_{2}, r_{3}\right] \equiv A$ generates $^{i} N_{1} ;$ $A$ sends ${ }^{i}\left\{N_{1}, A\right\}_{Q}^{r_{1}} ; A$ receives $^{i}\left\{N_{1}, n_{2}, Q\right\}_{A}^{s_{2}} ; A$ sends $^{i}\left\{n_{2}\right\}_{Q}^{r_{3}}$
$\operatorname{Resp}_{\mathrm{NSL}}^{B}\left[B, i^{\prime}, Q^{\prime}, n_{1}, N_{2}, s_{1}, r_{2}, s_{3}\right] \equiv B$ receives $^{i^{\prime}}\left\{n_{1}, Q^{\prime}\right\}_{B}^{s_{1}} ;$ $B$ generates ${ }^{i^{\prime}} N_{2} ; B$ sends $^{i^{\prime}}\left\{n_{1}, N_{2}, B\right\}_{Q^{\prime}}^{r_{2}} ; B$ receives $^{i^{\prime}}\left\{N_{2}\right\}_{B}^{s_{3}}$

They further have to agree that $Q=A, Q^{\prime}=B, n_{1}=N_{1}$, $n_{2}=N_{2}$.

Remark 2.4. Notice that, for example, in the responder's role, we wrote $B$ receives ${ }^{i^{\prime}}\left\{n_{1}, Q^{\prime}\right\}_{B}^{s_{1}}$. We used $n_{1}, Q^{\prime}$, $s_{1}$, which, according to our notation are of sort bitstring because they may have been created by adversary and therefore, be arbitrarily distributed.

Example 2.5. Roles of the amended NeedhamSchroeder shared-key protocol. We consider the amended Needham-Schroeder shared-key protocol [17, 7], whose informal description is as follows.

$$
\begin{aligned}
& \text { 1. } A \rightarrow B: A \\
& \text { 2. } B \rightarrow A:\left\{A, N_{1}\right\}_{B T} \\
& \text { 3. } A \rightarrow T:\left\langle A, B, N_{2},\left\{A, N_{1}\right\}_{B T}\right\rangle \\
& \text { 4. } T \rightarrow A:\left\{N_{2}, B, K,\left\{K, N_{1}, A\right\}_{B T}\right\}_{A T} \\
& \text { 5. } A \rightarrow B:\left\{K, N_{1}, A\right\}_{B T} \\
& \text { 6. } B \rightarrow A:\left\{N_{3}\right\}_{K} \\
& \text { 7. } A \rightarrow B:\left\{N_{3}, A\right\}_{K}
\end{aligned}
$$

In the original protocol, there is $N_{3}-1$ instead of $\left\langle N_{3}, A\right\rangle$, but for now we don't want to extend our syntax with additional functions. We have to assume that $A$ and the pairing are such that $\overline{\left\langle N_{3}, A\right\rangle} \neq \Delta N_{3}$.

The initiator's, the responder's and the trusted party's roles are described as the following formulas. We consider only a single trusted party, so we introduce a constant $T$ of sort hname for it.

Init $_{s N S}^{A}\left[T, A, i, Q_{2}, m_{1}, m_{2}, k, N_{2}, n_{3}, s_{3}, s_{4}, r_{5}\right] \equiv$ $A$ sends ${ }^{i} A ; A$ receives ${ }^{i} m_{1} ; A$ generates ${ }^{i} N_{2}$; $A$ sends ${ }^{i}\left\langle A, Q_{2}, N_{2}, m_{1}\right\rangle ; A$ receives ${ }^{i}\left\{N_{2}, Q_{2}, k, m_{2}\right\}_{A T}^{s_{3}} ;$ $A$ sends ${ }^{i} m_{2} ; A$ receives $^{i}\left\{n_{3}\right\}_{k}^{s_{4}} ; A$ sends $^{i}\left\{n_{3}, A\right\}_{k}^{r_{5}}$
$\operatorname{Resp}_{s N S}^{B}\left[T, B, i^{\prime}, Q_{1}, k^{\prime}, N_{1}, N_{3}, r_{1}, s_{2}, r_{4}, s_{5}\right] \equiv$ $B$ receives $^{i^{\prime}} Q_{1} ; B$ generates ${ }^{i^{\prime}} N_{1} ; B$ sends $^{i^{\prime}}\left\{Q_{1}, N_{1}\right\}_{B T}^{r_{1}}$; $B$ receives $^{{ }^{\prime}}\left\{k^{\prime}, N_{1}, Q_{1}\right\}_{B T}^{s_{2}} ; B$ generates ${ }^{i^{i}} N_{3}$; $B$ sends $^{i^{\prime}}\left\{N_{3}\right\}_{k^{\prime}}^{r_{4}} ; B$ receives $^{i^{\prime}}\left\{N_{3}, Q_{1}\right\}_{k^{\prime}}^{s_{5}}$
Trust ${ }_{s N S}^{T}\left[T, i^{\prime \prime}, Q_{1}^{\prime}, Q_{2}^{\prime}, K, n_{1}, n_{2}, s_{1}, r_{2}, r_{3}\right] \equiv$ $T$ receives $^{i^{\prime \prime}}\left\langle Q_{1}^{\prime}, Q_{2}^{\prime}, n_{2},\left\{Q_{1}^{\prime}, n_{1}\right\}_{Q_{2}^{\prime} T}\right\rangle ; T$ generates ${ }^{i^{\prime \prime}} K$; $T$ sends ${ }^{i^{\prime \prime}}\left\{n_{2}, Q_{2}^{\prime}, K,\left\{K, n_{1}, Q_{1}^{\prime}\right\}_{Q_{2}^{\prime} T}^{r_{2}}\right\}_{Q_{1}^{\prime} T}^{r_{3}}$
They further have to agree that $Q_{1}=Q_{1}^{\prime}=A, Q_{2}=Q_{2}^{\prime}=$ $B, n_{1}=N_{1}, n_{2}=N_{2}, n_{3}=N_{3}, k=k^{\prime}=K^{\prime}$.

Remark 2.6. Notice the variables $m_{1}$ and $m_{2}$ in the initiator's role. For example, the role says $\quad$ Areceives $^{i}\left\{N_{2}, Q_{2}, k, m_{2}\right\}_{A T}^{s_{3}}$ instead of A receives ${ }^{i}\left\{N_{2}, Q_{2}, k,\left\{k, N_{1}, Q_{1}\right\}_{Q_{2} T}^{s_{2}}\right\}_{A T}^{s_{3}}$. The reason is, that $A$ does not parse that part of the message, it does not look into the encryption, just forwards $m_{2}$. In the course of the agreement proof, we show that $m_{2}=\overline{\left\{k, N_{1}, Q_{1}\right\}_{B T}^{s_{2}}}$ when $Q_{2}=B$.

### 2.2. Agreement and authentication

The authentication and agreement properties that we consider have the following general pattern: An honest principal thinks he finished a session with certain other principals. Assuming that the others are also honest, we would like to prove that he really did communicate with the others, the others finished their parts, and the sent and received items that should be the same according the the protocol, were indeed the same.

For example, in case of the symmetric NS protocol, if the responder $B$ finished a session with $A$ and $T$, that is,

$$
\operatorname{Resp}_{s N S}^{B}\left[T, A, i^{\prime}, Q_{1}, k^{\prime}, N_{1}, N_{3}, r_{1}, s_{2}, r_{4}, s_{5}\right]
$$

is satisfied, and the others are carrying out their roles honestly, and generate and encrypt honestly, then we want to show that the others did have a session with the responder, and they agree on the messages involved. We want to prove that for some $i, i^{\prime \prime}, N_{2}, m_{1}, m_{2}, s_{1}, r_{2}, s_{3}, r_{3}, s_{4}, r_{5}$,

$$
\begin{gathered}
\operatorname{Init}_{s N S}^{A}\left[T, A, i, B, m_{1}, m_{2}, k^{\prime}, N_{2}, n_{3}, s_{3}, s_{4}, r_{5}\right] \\
\quad \operatorname{Trust}_{s N S}^{T}\left[T, i^{\prime \prime}, A, B, k^{\prime}, N_{1}, N_{2}, s_{1}, r_{2}, r_{3}\right]
\end{gathered}
$$

are also satisfied.
We first need to formulate what it means to follow the roles honestly and not doing anything else. Let us introduce the following abbreviation:

$$
\begin{aligned}
& O_{n l y}\left(A_{\text {acts }}^{1}{ }_{1}^{i} t_{1} ; \ldots ; A \text { acts }{ }_{k}^{i} t_{k}\right) \equiv \\
& \exists \tau_{1} \ldots \tau_{k}\left(\text { A acts }_{1, \tau_{1}}^{i} t_{1} ; \ldots ; \text { acts } s_{k, \tau_{k}}^{i} t_{k} \wedge\right. \\
& \forall \tau_{1}^{\prime} \ldots \tau_{k}^{\prime} t_{1}^{\prime} \ldots t_{k}^{\prime}\left(\left(\text { A acts }_{1, \tau_{1}}^{i} t_{1}^{\prime} ; \ldots ; \text { acts }_{k, \tau_{k}^{\prime}}^{i} t_{k}^{\prime}\right.\right. \\
& \left.\rightarrow \bigwedge_{j} \tau_{j}=\tau_{j}^{\prime} \wedge t_{j}=t_{j}^{\prime}\right) \\
& \left.\left.\bigwedge_{\left(\text {acts }_{k+1}, \ldots, \text { acts }_{k+l}\right):} \neg \operatorname{aacts}_{k+1, \tau_{1}^{\prime}}^{i} t_{1}^{\prime} ; \ldots ; A \operatorname{acts}_{k+l, \tau_{k}^{i}}^{i} t_{k}^{\prime}\right)\right)\left.\right|_{\Delta} \\
& l \in\{1, \ldots, k+1\} \wedge \\
& \left(\text { acts }_{k+1}, \ldots, \text { acts }_{k+l}\right) \& \\
& \left(\text { acts }_{1}, \ldots, \text { acts }_{k}\right)
\end{aligned}
$$

The meaning of this is that $A$ in session $i$ carries out these and only these actions. It is a consequence of this definition that for $\vec{\alpha}^{A, i}, \vec{\beta}^{A, i}$, if $\vec{\beta}^{A, i} \nsubseteq \vec{\alpha}^{A, i}$, then

$$
\text { Only }\left._{\Delta}\left(\vec{\alpha}^{A, i}\right) \rightarrow\left(\vec{\alpha}^{A, i} \wedge \neg \vec{\beta}^{A, i}\right)\right|_{\Delta}
$$

For $\vec{\alpha}^{A, i} \equiv \alpha_{1}^{A, i} ; \ldots ; \alpha_{n}^{A, i}$ and $0 \leq j \leq n$, let $\vec{\alpha}_{\leq j}^{A, i}$ denote an initial segment of $\vec{\alpha}^{A, i}$ ending with $\alpha_{j}^{A, i}$, i.e.,

$$
\vec{\alpha}_{\leq j}^{A, i} \equiv \alpha_{1}^{A, i} ; \cdots ; \alpha_{j}^{A, i} .
$$

Let Only $_{\Delta}\left(\vec{\alpha}_{\leq 0}^{A, i}\right) \equiv \neg \exists t\left(\right.$ A generates $^{i} t \vee A$ sends $^{i} t \vee$ $A$ receives $\left.{ }^{i} t\right)\left.\right|_{\Delta}$ and $S=\{0, n\} \cup\left\{j \mid \exists t\left(\alpha_{j}^{A, i}=A\right.\right.$ sends $\left.\left.{ }^{i} t\right)\right\}$,

$$
\operatorname{Foll}\left(\vec{\alpha}^{A, i}\right) \equiv \forall \Delta \bigvee_{j \in S} O n l y_{\Delta}\left(\vec{\alpha}_{\leq j}^{A, i}\right)
$$

This formula means that $A$ in session $i$ does nothing but follow $\vec{\alpha}^{A, i}$, and may finish it, or stop after a send action, but not after a receive action. Finally, for $\alpha^{A, i}[A, i, \vec{m}]$, let

$$
F O L L\left(\alpha^{A}\right) \equiv \forall i \exists \vec{m} \operatorname{Foll}\left(\alpha^{A, i}[A, i, \vec{m}]\right)
$$

that is, $A$, in each of its sessions, follows $\alpha^{A}$ with some values. For example, a principal is carrying out the symmetric Needham-Schroeder protocol's initiator's role in each of his sessions and does nothing else, if

$$
\begin{aligned}
& F O L L\left(\text { Init }_{\mathrm{NSL}}^{A}\right) \equiv \\
& \forall i \exists Q_{2} m_{1} m_{2} k N_{2} n_{3} s_{3} s_{4} r_{5} \\
& \operatorname{Foll}\left(\operatorname{Init}_{s N S}^{A}\left[T, A, i, Q_{2}, m_{1}, m_{2}, k, N_{2}, n_{3}, s_{3}, s_{4}, r_{5}\right]\right)
\end{aligned}
$$

In general, the authentication property from $A$ 's view has the following form:

$$
\text { Role }^{A, i}[\vec{A}] \wedge \bigwedge_{B \sqsubseteq \vec{A}} F O L L\left(\text { Role }^{B}[\vec{Q}]\right) \rightarrow \bigwedge_{B \sqsubseteq \vec{A}} \exists i^{\prime} \text { Role }^{B, i^{\prime}}[\vec{A} / \vec{Q}]
$$

Meaning that if principal $A$ finishes his role playing with principals in $\vec{A}$ who honestly follow their roles playing with some principals $\vec{Q}$, then they all have a session that they carried out with the group $\vec{A}$. Agreement further requires some values of their roles to match. In case of the symmetric NS protocol, authentication together with agreement from the responder's view takes the form:

$$
\begin{align*}
& \operatorname{Resp}_{s N S}^{B}\left[T, B, i^{\prime}, A, k, N_{1}, N_{3}, r_{1}, s_{2}, r_{4}, s_{5}\right] \\
& \wedge F O L L\left(\operatorname{Init}_{\mathrm{sNS}}^{A}\right) \wedge F O L L\left(\operatorname{Resp}_{\mathrm{sNS}}^{B}\right) \wedge F O L L\left(\operatorname{Trust}_{\mathrm{sNS}}^{T}\right) \\
& \vdash \exists i i^{\prime \prime} m_{1} m_{2} N_{2} s_{1} r_{2} r_{3} s_{3} s_{4} r_{5}  \tag{1}\\
& \left(\operatorname{Init}_{\mathrm{sNS}}^{A}\left[T, A, i, B, m_{1}, m_{2}, k, N_{2}, N_{3}, s_{3}, s_{4}, r_{5}\right]\right. \\
& \left.\wedge \operatorname{Trust}_{s N S}^{T}\left[T, i^{\prime \prime}, A, B, k, N_{1}, N_{2}, s_{1}, r_{2}, r_{3}\right]\right)
\end{align*}
$$

### 2.3. Secrecy Preservation

As we mentioned in the introduction, the central idea of our system is to prove first that the send actions of honest participants in a protocol do not corrupt the secrecy of nonces or keys. That is, if they were secret before the send action, then they are secret immediately after. Of course, some nonces and keys may be revealed and are revealed without any problem. For example, those nonces that were generated by an honest participant in a session that is played with a corrupted participant are of course allowed to be revealed. The first idea that comes to mind is that we prove this secrecy preservation for nonces or keys $\nu$ that satisfy some condition $C[\nu]$. Therefore, we want to prove is something like

$$
\begin{aligned}
& \forall A i t \nu \tau \Delta\left(A \sqsubseteq \vec { A } \wedge C [ \nu ] \wedge A \operatorname { s e n d s } _ { \tau } ^ { i } t \wedge \left[\operatorname{Key}^{\prime} \operatorname{Sec}_{\tau}(\vec{A}, \nu)\right.\right. \\
& \left.\longrightarrow[\operatorname{Key}] \operatorname{Sec}_{\tau}(\vec{A}, t, \nu)\right)\left.\right|_{\Delta}
\end{aligned}
$$

which is actually two properties, one with $K e y$, one without it. This would mean that for each send action of the principals of the group $\vec{A}$, if any $\nu$ satisfying $C[\nu]$ is a secret of
the group before the send action, then it is not corrupted via the send action, as revealing the sent item maintains the secrecy of it. If we could prove this for a protocol, then it would ensure the secrecy of such $\nu$ 's all the way trough as they are never revealed. However, this turns out to be normally impossible to prove. The property that we need is that if secrecy before the send action holds even if we reveal certain other things, then the secrecy is not corrupted with the send action. So accordingly, we define the following property: Let $C[\nu]$ be a closed condition on $\nu$, and $C^{\prime}[u]$ a closed condition on term $u$.

$$
\begin{align*}
& {[\text { Key }] \operatorname{SecSend}\left(\vec{A}, C, C^{\prime}\right) \equiv} \\
& \forall A i t \nu u \tau \Delta\left(A \sqsubseteq \vec{A} \wedge C[\nu] \wedge C^{\prime}[u] \wedge \nu \nsubseteq u \wedge A \operatorname{sends}_{\tau}^{i} t\right.  \tag{2}\\
& \left.\wedge \forall u^{\prime} \Delta^{\prime}\left(\Delta^{\prime} \subseteq \Delta \wedge C^{\prime}\left[u^{\prime}\right] \wedge \nu \nsubseteq u^{\prime} \rightarrow\left[\operatorname{Key}^{\prime}\right] \operatorname{Sec}_{\tau}\left(\vec{A}, u^{\prime}, \nu\right)\right)\right|_{\Delta^{\prime}} \\
& \left.\longrightarrow[K e y] \operatorname{Sec}_{\tau}(\vec{A},\langle t, u\rangle, \nu)\right)\left.\right|_{\Delta}
\end{align*}
$$

Or, somewhat relaxed version is also sufficient:

$$
\begin{align*}
& {[\text { Key }] \operatorname{SecSend}(\vec{A}, \hat{C}) \equiv \forall A i t u \nu \tau \Delta\left(A \sqsubseteq \vec{A} \wedge \hat{C}[\nu, u] \wedge A \operatorname{sends}{ }_{\tau}^{i} t\right.} \\
& \left.\wedge \forall \nu^{\prime} u^{\prime} \Delta^{\prime}\left(\Delta^{\prime} \subseteq \Delta \wedge \hat{C}\left[\nu^{\prime}, u^{\prime}\right] \rightarrow[K e y] \operatorname{Sec}_{\tau}\left(\vec{A}, u^{\prime}, \nu^{\prime}\right)\right)\right|_{\Delta^{\prime}}  \tag{3}\\
& \left.\longrightarrow[\text { Key }] \operatorname{Sec}_{\tau}(\vec{A},\langle t, u\rangle, \nu)\right)\left.\right|_{\Delta}
\end{align*}
$$

with $\hat{C}[\nu, u]$ a condition on $\nu$ and $u$.
Example 2.7. (Preservation of Secrecy in the Needham-Schroeder-Lowe protocol) For example, in case of the NSL protocol, where $\vec{A}=\langle A, B\rangle$, we can prove this property fixing $C$ as

$$
\left.\begin{array}{rl}
C[N] \equiv & \exists i r n\left(A \text { generates }^{i} N ; A \text { sends }^{i}\{N, A\}_{B}^{r}\right. \\
& \vee B \text { generates }
\end{array}{ }^{i} ; B \text { sends }^{i}\{n, N, B\}_{A}^{r}\right)
$$

and $C^{\prime}$ as

$$
\begin{array}{r}
C^{\prime}[u] \equiv \forall t\left(t \sqsubseteq u \rightarrow \exists m(t=m) \vee \exists t_{1} t_{2}\left(t=\left\langle t_{1}, t_{2}\right\rangle\right)\right. \\
\wedge \forall m\left(m \sqsubseteq u \rightarrow \exists i\left(\text { A generates }^{i} m \vee B \text { generates }^{i} m\right)\right)
\end{array}
$$

Here, $C[N]$ expresses that $N$ was generated by $A$ and intended to $B$, or $N$ was generated by $B$ and intended to $A$. The formula $\operatorname{Sec} \operatorname{Send}(N, u)$ guarantees the preservation of the secrecy of such a nonce. Of course, if $N$ does not satisfy these conditions, that is, if it was not intended to be between $A$ and $B$, then we do not care about its secrecy. The first line of $C^{\prime}[u]$ line expresses that the only function symbol that appears in $u$ is the pairing, and the second line expresses that all bitstrings of $u$ were generated by $A$ or $B$. So we have that $u$ has the form $u=\left\langle N_{1}, \ldots, N_{j}\right\rangle$, where $N_{1}, \ldots, N_{j}$ were all generated by $A$ or $B$. Then $N \nsubseteq u$ expresses that $N \neq N_{i}$ for $1 \leq i \leq j$. So what SecSend tells us is that for each message that was sent by $A$ or $B$, if all $N$ 's that were intended to be between $A$ and $B$, were the secret of $A$ and $B$ before a send action, even when the other
nonces generated by $A$ and $B$ are revealed, then all such $N$ 's remain secret after sending the message.
Example 2.8. (Preservation of Secrecy in the symmetric Needham-Schroeder protocol) In case of the symmetric NS protocol, where $\vec{A}=\langle A, B, T\rangle$, we can prove for example the preservation of secrecy of the shared key by fixing $C$ as

$$
\begin{aligned}
C[K] \equiv & \exists i^{\prime \prime} n_{1} n_{2} r_{2} r_{3}\left(T \text { generates }{ }^{i^{\prime \prime}} K\right. \\
& \left.T \text { sends }^{i^{\prime \prime}}\left\{n_{2}, B, K,\left\{K, n_{1}, A\right\}_{B T}^{r_{2}}\right\}_{A T}^{r_{3}}\right)
\end{aligned}
$$

And $C^{\prime}[u]$ as

$$
\begin{array}{r}
\quad C^{\prime}[u] \equiv \forall t\left(t \sqsubseteq u \rightarrow \exists m(t=m) \vee \exists t_{1} t_{2}\left(t=\left\langle t_{1}, t_{2}\right\rangle\right)\right. \\
\wedge \forall m\left(m \sqsubseteq u \rightarrow \exists i\left(T \text { generates }{ }^{i} m \vee B \text { generates }{ }^{i} m\right)\right)
\end{array}
$$

Here, too, $C[K]$ ensures that $K$ is generated by $T$, and meant for $A$ and $B$. With these definitions, we are able to prove KeySecSend $\left(\langle A, B, T\rangle, C, C^{\prime}\right)$.
Commitment problem. For the sake of discussing commitment but sticking to the symmetric NS protocol, let us now assume that we would want to prove the secrecy of $K$, and not the key secrecy. Since at a certain point, $B$ sends the message $\left\{N_{3}\right\}_{K}^{r_{4}}$, and $A$ sends $\left\{N_{3}, A\right\}_{K}^{r_{5}}$. From this on, $K$ becomes distinguishable from another randomly generated key. In fact, already after sending $\left\{N_{3}\right\}_{K}^{r_{4}}, K$ may already not be indistinguishable. So there is no hope to prove SecSend in its previous form, for all send actions of $A$ and $B$ and $T$. Let

$$
\operatorname{Reveal}_{\tau}(\langle A, B, T\rangle, K)\left[N_{3}, r_{4}\right] \equiv B \operatorname{sends}_{\tau}^{i^{\prime}}\left\{N_{3}\right\}_{K}^{r_{4}}
$$

Then, instead of (2), we can prove

$$
\begin{aligned}
& \operatorname{SecSend}\left(\vec{A}, C, C^{\prime}, \text { Reveal }\right) \equiv \\
& \forall A i t \nu u \tau \vec{m} \Delta\left(A \sqsubseteq \vec{A} \wedge C(\nu) \wedge C^{\prime}[u] \wedge \nu \nsubseteq u \wedge A \text { sends }_{\tau}^{i} t\right. \\
& \left.\wedge \forall \Delta^{\prime}\left(\Delta^{\prime} \subseteq \Delta \wedge \text { Reveal }_{\tau^{\prime}}(\vec{A}, \nu)[\vec{m}] \rightarrow \tau<\tau^{\prime}\right)\right|_{\Delta^{\prime}} \\
& \wedge \forall u^{\prime} \Delta^{\prime}\left(\Delta ^ { \prime } \subseteq \Delta \wedge C ^ { \prime } [ u ^ { \prime } ] \wedge \nu \nsubseteq u ^ { \prime } \rightarrow \left[{\text { Key } \left.] \operatorname{Sec}_{\tau}\left(\vec{A}, u^{\prime}, \nu^{\prime}\right)\right)\left.\right|_{\Delta^{\prime}}}^{\left.\longrightarrow\left[\text { Key }^{\prime} \operatorname{Sec}_{\tau}(\vec{A},\langle t, u\rangle, \nu)\right)\right|_{\Delta}}\right.\right.
\end{aligned}
$$

### 2.4. The Axioms of Basic Protocol Logic 2.0

Finally, we present the axioms. We extend the usual firstorder predicate logic with equality by adding the following sets of axioms.
(I) Axioms for the stochastic structure of the sets branches of coin tosses.
(1) Events
(a) $\Delta_{1} \subseteq_{\Delta} \Delta_{2} \wedge \Delta_{2} \subseteq_{\Delta} \Delta_{3} \rightarrow \Delta_{1} \subseteq_{\Delta} \Delta_{3}$;
(b) $\Delta_{1} \subseteq_{\Delta} \Delta_{2} \wedge \Delta_{1} \subseteq_{\Delta} \Delta_{2} \leftrightarrow \Delta_{1}=\Delta_{\Delta} \Delta_{2}$;
(c) $\Delta \subseteq \mathbf{D}$
(d) $\Delta_{1} \subseteq \Delta \wedge \Delta_{1} \subseteq \Delta \Delta_{2} \rightarrow \Delta_{1} \subseteq \Delta_{2}$
(e) $\Delta^{\prime} \subseteq \Delta \wedge \Delta_{1} \subseteq_{\Delta} \Delta_{2} \rightarrow \Delta_{1} \subseteq_{\Delta^{\prime}} \Delta_{2}$
(f) $\exists \Delta\left(\Delta_{1} \subseteq \Delta \wedge \Delta_{2} \subseteq \Delta \wedge \forall \Delta^{\prime}\left(\Delta_{1} \subseteq \Delta^{\prime} \wedge \Delta_{2} \subseteq \Delta^{\prime} \rightarrow\right.\right.$ $\left.\Delta \subseteq \Delta^{\prime}\right)$ ). It is possible to show that all such $\Delta^{\prime}$ 's are equal, so it is unique, and we can call it $\Delta_{1} \cup \Delta_{2}$.
(2) Time sections
(a) $\tau_{1}<\Delta \tau_{2} \wedge \tau_{2}<\Delta \tau_{3} \rightarrow \tau_{1}<\Delta \tau_{3}$; $\neg\left(\tau_{1}<\Delta \tau_{2} \wedge \tau_{2}<\Delta \tau_{1}\right) ;$
(b) $\mathbf{0}<\Delta \tau \vee \tau=\Delta \mathbf{0}$; $\tau<\Delta \mathbf{1} \rightarrow \tau=\Delta \mathbf{0}$; $\tau<\Delta \infty \vee \tau=\Delta \infty$;
(c) $\left.\left(\forall \Delta\left(\tau \nless \Delta \tau^{\prime} \wedge \tau^{\prime} \nless \Delta \tau\right) \rightarrow \tau=\tau^{\prime}\right)\right|_{\Delta^{\prime}}$
(II) Reflexibility and substitution properties of $={ }_{\Delta}$. They express that $={ }_{\Delta}$ has the usual properties of equation in first order logic when the predicates are restricted to $\Delta$.
(1) $v=\Delta v$;
(2) For any function symbol $f$,

$$
v={ }_{\Delta} v^{\prime} \rightarrow f(\ldots, v, \ldots)=\Delta f\left(\ldots, v^{\prime}, \ldots\right)
$$

(3) If $\varphi_{0}$ is any of the atomic formulas without $\left.\right|_{\Delta}, v$ is a variable in $\varphi_{0}$ and $\varphi_{0}^{\prime}$ is a formula that we get from $\varphi_{0}$ by replacing some occurrences of $v$ by $v^{\prime}$, then

$$
v=\left.\left.{ }_{\Delta} v^{\prime} \wedge \varphi_{0}\right|_{\Delta} \rightarrow \varphi_{0}^{\prime}\right|_{\Delta}
$$

## (III) Restriction of formulas by $\left.\right|_{\Delta}$.

(1) Restriction of formulas. The meaning of this is that the atomic formulas are such that they keep their validity by restriction. For example, if two terms are equal on $\Delta$, they are equal on every subsets of $\Delta$; if a term was sent on a set, it was sent also on every subset, etc.

If $\varphi_{0}$ is an atomic formula without $\left.\right|_{\Delta}$, then

$$
\left.\left.\Delta^{\prime} \subseteq \Delta \wedge \varphi_{0}\right|_{\Delta} \rightarrow \varphi_{0}\right|_{\Delta^{\prime}}
$$

(2) Extension of formulas to unions:
(a) If $\varphi_{0}^{\prime}$ is either an atomic formula without $\left.\right|_{\Delta}$ and without $\sqsubseteq$, or is a negation of any atomic formula, then

$$
\left.\left.\left.\varphi_{0}\right|_{\Delta_{1}} \wedge \varphi_{0}\right|_{\Delta_{2}} \rightarrow \varphi_{0}\right|_{\Delta_{1} \cup \Delta_{2}}
$$

The meaning this is that the atomic formulas remain valid by unions.
(b) Existence of a term satisfying $\varphi$ on two events results in the existence of such a term on the union of these two events as long as $\varphi$ is restrictable and extendible to unions.

$$
\begin{aligned}
& \exists t /\left.\tau \varphi\right|_{\Delta_{1}} \wedge \exists t /\left.\tau \varphi\right|_{\Delta_{2}} \\
& \quad \wedge \forall \Delta^{\prime}\left(\left.\left.\Delta^{\prime} \subseteq \Delta \wedge \varphi\right|_{\Delta} \rightarrow \varphi\right|_{\Delta^{\prime}}\right) \\
& \quad \wedge \forall \Delta_{1} \Delta_{2}\left(\left.\left.\left.\varphi\right|_{\Delta_{1}} \wedge \varphi\right|_{\Delta_{2}} \rightarrow \varphi\right|_{\Delta_{1} \cup \Delta_{2}}\right) \\
& \rightarrow \exists t /\left.\tau \varphi\right|_{\Delta_{1} \cup \Delta_{2}}
\end{aligned}
$$

(3) The meaning of this is, that if for all $\Delta, \varphi$ on $\Delta$ implies $\varphi^{\prime}$ on a subset of $\Delta$, if $\varphi$ keeps its validity by restriction, and if $\varphi^{\prime}$ keeps its validity by restriction and union, then we have that $\varphi$ on $\Delta$ implies $\varphi^{\prime}$ on $\Delta$. So it is enough to prove $\varphi^{\prime}$ on a subset of each set. (The soundness proof of this is not difficult: the largest subset of $\Delta$, where $\varphi^{\prime}$ holds must be $\Delta$, otherwise easily get a contradiction by making it even larger.) Let $\varphi$ and $\varphi^{\prime}$ any formulas. Then

$$
\begin{aligned}
\left.\varphi\right|_{\Delta} & \rightarrow \exists \Delta^{\prime}\left(\left.\Delta^{\prime} \subseteq \Delta \wedge \varphi^{\prime}\right|_{\Delta^{\prime}}\right) \\
& \wedge \forall \Delta^{\prime}\left(\left.\left.\Delta^{\prime} \subseteq \Delta \wedge \varphi\right|_{\Delta} \rightarrow \varphi\right|_{\Delta^{\prime}}\right) \\
& \wedge \forall \Delta^{\prime}\left(\left.\left.\Delta^{\prime} \subseteq \Delta \wedge \varphi^{\prime}\right|_{\Delta} \rightarrow \varphi^{\prime}\right|_{\Delta^{\prime}}\right) \\
& \wedge \forall \Delta_{1} \Delta_{2}\left(\left.\left.\left.\varphi^{\prime}\right|_{\Delta_{1}} \wedge \varphi^{\prime}\right|_{\Delta_{2}} \rightarrow \varphi^{\prime}\right|_{\Delta_{1} \cup \Delta_{2}}\right) \\
& \longrightarrow\left(\left.\left.\varphi\right|_{\Delta} \rightarrow \varphi^{\prime}\right|_{\Delta}\right)
\end{aligned}
$$

(IV) Term axioms. These are the axioms that result the examples we listed in Example 2.2. They also express that pairing is invertible, that a ciphertext decrypts to the correct plaintext by the correct key. They also express that correctly generated nonces, keys, encryptions cannot be the same random variables as other correctly generated items. Etc.
(1) Axioms for $=$ with not involving -
(a) $\left\langle t_{1}, t_{2}\right\rangle=\Delta\left\langle t_{1}^{\prime}, t_{2}^{\prime}\right\rangle \rightarrow t_{1}=\Delta t_{1}^{\prime} \wedge t_{2}=\Delta t_{2}^{\prime}$;
(b) $\{t\}_{Q}^{s}=\Delta\left\{t^{\prime}\right\}_{Q^{\prime}}^{s^{\prime}} \rightarrow t=\Delta t^{\prime} \wedge Q={ }_{\Delta} Q^{\prime}$;
$\{t\}_{Q_{1} Q_{2}}^{s}=\Delta\left\{t^{\prime}\right\}_{Q_{1}^{\prime} Q_{2}^{\prime}}^{s^{\prime}} \rightarrow t=\Delta t^{\prime} \wedge\left(\left(Q_{1}=\Delta Q_{1}^{\prime} \wedge Q_{2}=\Delta\right.\right.$
$\left.\left.Q_{2}^{\prime}\right) \vee\left(Q_{1}=\Delta Q_{2}^{\prime} \wedge Q_{2}=\Delta Q_{1}^{\prime}\right)\right) ;$
$\{t\}_{k}^{s}=\Delta\left\{t^{\prime}\right\}_{k^{\prime}}^{s^{\prime}} \rightarrow t=\Delta t^{\prime} \wedge k=\Delta k^{\prime} ;$
(c) $\{t\}_{Q}^{s} \neq \Delta\left\langle t_{1}, t_{2}\right\rangle ; \quad\{t\}_{Q}^{s} \neq \Delta m ; \quad\{t\}_{Q}^{s} \neq \Delta$ $\left\{t^{\prime}\right\}_{Q_{1} Q_{2}}^{s} ; \quad\{t\}_{Q_{1} Q_{2}}^{s} \neq \Delta\left\langle t_{1}, t_{2}\right\rangle ; \quad\{t\}_{Q_{1} Q_{2}}^{s} \neq \Delta m ;$ $m \neq \Delta\left\langle t_{1}, t_{2}\right\rangle ; \quad\{t\}_{k}^{s} \neq \Delta\left\langle t_{1}, t_{2}\right\rangle ; \quad\{t\}_{k}^{s} \neq \Delta m$
(d) $A \neq \Delta N ; \quad A \neq \Delta K ; \quad A \neq A^{\prime} \rightarrow A \neq \Delta A^{\prime}$;
(e) $\{t\}_{Q_{1} Q_{2}}^{s}=\Delta\{t\}_{Q_{2} Q_{1}}^{s}$;
(2) Axioms for $=$ with involving -
(a) $\bar{m}=\Delta m$;
(b) For any function symbol $f, \overline{f(\ldots, t, \ldots)}={ }_{\Delta} \overline{f(\ldots, \bar{t}, \ldots)}$;
(c) $\perp \neq \Delta t_{1} \wedge \perp \neq \Delta t_{2} \rightarrow \perp \neq \Delta\left\langle t_{1}, t_{2}\right\rangle$;
$\perp \neq \Delta \overline{\left\langle t_{1}, t_{2}\right\rangle}==_{\Delta} \overline{\left\langle t_{1}^{\prime}, t_{2}^{\prime}\right\rangle} \rightarrow \overline{t_{1}}==_{\Delta} \overline{t_{1}^{\prime}} \wedge \overline{t_{2}}={ }_{\Delta} \overline{t_{2}^{\prime}} ;$
$\perp \neq \Delta \overline{\{t\}_{Q}^{s}}=\Delta \overline{\left\{t^{\prime}\right\}_{Q}^{s^{\prime}}} \rightarrow \bar{t}=\Delta \overline{t^{\prime}} ;$
$\perp \neq \Delta \overline{\{t\}_{Q_{1} Q_{2}}^{s}}={ }_{\Delta} \overline{\left\{t^{\prime}\right\}_{Q_{1} Q_{2}}^{s^{\prime}}} \rightarrow \bar{t}=\Delta \overline{t^{\prime}} ;$
$\perp \neq \Delta \overline{\{t\}_{k}^{s}}={ }_{\Delta} \overline{\left\{t^{\prime}\right\}_{k}^{s^{\prime}}} \rightarrow \bar{t}={ }_{\Delta} \overline{t^{\prime}} ;$

(f) For any compound term $T$ containing only variables of sort hseed, hname, hkey or hnonce,
$\left(\left(N \sqsubseteq T \wedge N \neq N^{\prime}\right) \vee K \sqsubseteq T \vee\{t\}^{r} \sqsubseteq T \rightarrow \bar{T} \neq N^{\prime} \vee \bar{T}=\right.$ $\left.N^{\prime}=\perp\right)\left.\right|_{\Delta} ; \quad\left(N \sqsubseteq T \vee\left(K \sqsubseteq T \wedge K \neq K^{\prime}\right) \vee\{t\}^{r} \ldots \sqsubseteq \rightarrow\right.$ $\left.\bar{T} \neq K^{\prime} \vee \bar{T}=K^{\prime}=\perp\right)\left.\right|_{\Delta} ;$
(g) For any function symbol $f, \overline{f(\ldots, \perp, \ldots)}={ }_{\Delta} \perp$;
(3) Axioms for $\sqsubseteq$
(a) $t_{1} \sqsubseteq \Delta t_{2} \wedge t_{2} \sqsubseteq \Delta t_{3} \rightarrow t_{1} \sqsubseteq \Delta t_{3}$;
(b) $t \sqsubseteq \Delta t_{1} \vee t \sqsubseteq \Delta t_{2} \rightarrow t \sqsubseteq_{\Delta}\left\langle t_{1}, t_{2}\right\rangle$;
(c) $t_{1} \sqsubseteq_{\Delta} t_{2} \rightarrow t_{1} \sqsubseteq \Delta\left\{t_{2}\right\}_{Q}^{s} ; \quad t_{1} \sqsubseteq_{\Delta} t_{2} \rightarrow t_{1} \sqsubseteq \Delta$ $\left\{t_{2}\right\}_{Q_{1} Q_{2}}^{s} ; \quad t_{1} \sqsubseteq \Delta t_{2} \rightarrow t_{1} \sqsubseteq \Delta\left\{t_{2}\right\}_{k}^{s} ;$
(4) Axioms for $\sqsubseteq$ and $=$
(a) $t_{1}=\Delta t_{2} \rightarrow t_{1} \sqsubseteq \Delta t_{2} ; \quad t_{1} \sqsubseteq \Delta t_{2} \wedge t_{2} \sqsubseteq \Delta t_{1} \rightarrow t_{1}=\Delta t_{2}$;
(b) $t \sqsubseteq \Delta m \rightarrow t=\Delta m$;
(c) $t \sqsubseteq \Delta\left\langle t_{1}, t_{2}\right\rangle \rightarrow t \sqsubseteq \Delta t_{1} \vee t \sqsubseteq \Delta t_{2} \vee\left\langle t_{1}, t_{2}\right\rangle=\Delta t$;
(d) $t_{1} \sqsubseteq \Delta\left\{t_{2}\right\}_{Q}^{s} \rightarrow t_{1} \sqsubseteq \Delta t_{2} \vee\left\{t_{2}\right\}_{Q}^{s}=\Delta t_{1}$; $t_{1} \sqsubseteq \Delta\left\{t_{2}\right\}_{Q_{1} Q_{2}}^{s} \rightarrow t_{1} \sqsubseteq \Delta t_{2} \vee\left\{t_{2}\right\}_{Q_{1} Q_{2}}^{s}=\Delta t_{1} ;$ $t_{1} \sqsubseteq \Delta\left\{t_{2}\right\}_{k}^{s} \rightarrow t_{1} \sqsubseteq \Delta t_{2} \vee\left\{t_{2}\right\}_{k}^{s}=\Delta t_{1} ;$
(V) Trace with Secrecy: These axioms describe what can be revealed while still maintaining the secrecy of $\nu$. They are used in the course of proving [Key]SecSend, that is, that send actions don't corrupt keys and nonces. In order to make the formulas less messy, we introduce a shorthand notation: $\left.[K e y] \operatorname{Sec}_{\tau}\left(\vec{A}, t \xrightarrow{\varphi} t^{\prime}, \nu\right)\right|_{\Delta}$ means $\left.\varphi\right|_{\Delta} \wedge$ $\left.\left.[K e y] \operatorname{Sec}_{\tau}(\vec{A}, t, \nu)\right|_{\Delta} \rightarrow[K e y] \operatorname{Sec}_{\tau}\left(\vec{A}, t^{\prime}, \nu\right)\right|_{\Delta}$.
(a) Items that were not yet generated, cannot be already corrupted and cannot already corrupt:
$\left.\left(Q\right.$ generates $\left._{\tau}^{i} \nu \wedge \tau^{\prime}<\tau\right)\right|_{\Delta} \rightarrow\left[\right.$ Key $^{2}$ Sec $\left._{\tau^{\prime}}(\vec{A}, \nu)\right|_{\Delta} ;$
$\left(Q\right.$ generates $\left.{ }^{i} \nu \wedge \neg \exists t \tau \Delta^{\prime}\left(Q\right.$ sends $\left._{\tau}^{i} t \wedge \nu \sqsubseteq t \wedge \tau<\tau^{\prime}\right)\right|_{\Delta^{\prime}}$
$\left.\longrightarrow[K e y] \operatorname{Sec}_{\tau^{\prime}}(\vec{A}, \nu)\right)\left.\right|_{\Delta}$;
$[$ Key $]$ Sec $\left._{\tau^{\prime}}\left(\vec{A}, t \xrightarrow{Q \text { generates } \tau_{\tau}^{i} \nu^{\prime} \wedge \tau^{\prime}<\tau}\left\langle t, \nu^{\prime}\right\rangle, \nu\right)\right|_{\Delta} ;$
$\left.\left.[K e y] \operatorname{Sec}_{\tau^{\prime}}\left(\vec{A}, t \xrightarrow{Q \operatorname{gen}^{i} \nu^{\prime} \wedge \neg \exists t \tau \Delta^{\prime}\left(\nu^{\prime} \frac{\square}{Q} t \wedge \tau<\tau \operatorname{sends} \tau^{i}\right.}\right)\right|_{\Delta^{\prime}}\left\langle t, \nu^{\prime}\right\rangle, \nu\right)\left.\right|_{\Delta} ;$
(b) Names are public, so revealing them does not corrupt:
$\left.\left[K_{e y}\right] \operatorname{Sec}_{\tau}(\vec{A}, t \longrightarrow\langle t, Q\rangle, \nu)\right|_{\Delta} ;$
(c) Revealing something $t$ that was already revealed, shown by a send or receive action, cannot corrupt secrecy:
$\left.\left(Q\right.$ sends $_{\tau}^{i} t \vee Q$ receives $\left._{\tau}^{i} t\right)\right|_{\Delta} \wedge \tau<\Delta \tau^{\prime}$

$$
\left.\left.\wedge[K e y] S e c_{\tau^{\prime}}\left(\vec{A}, t^{\prime}, \nu\right)\right|_{\Delta} \rightarrow[K e y] S e c_{\tau^{\prime}}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle, \nu\right)\right|_{\Delta} ;
$$

(d) Something that is secret at time $\tau^{\prime}$, was also secret earlier:
$\tau<\left.\left.\Delta \tau^{\prime} \wedge[K e y] \operatorname{Sec}_{\tau^{\prime}}(\vec{A}, t, \nu)\right|_{\Delta} \rightarrow[$ Key $] \operatorname{Sec}_{\tau}(\vec{A}, t, \nu)\right|_{\Delta} ;$
(e) Secrecy relative to different groups of principals:
$\left.\forall A\left(A \sqsubseteq \vec{A} \rightarrow A \sqsubseteq \vec{A}^{\prime}\right) \wedge\left[K_{e y}\right] \operatorname{Sec}_{\tau}(\vec{A}, t, \nu)\right|_{\Delta}$
$\left.\rightarrow[$ Key $] \operatorname{Sec}_{\tau}\left(\vec{A}^{\prime}, t, \nu\right)\right|_{\Delta} ;$
(f) Manipulations of pairing inside the secrecy predicate:
$\left.[K e y] \operatorname{Sec}_{\tau}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle \longrightarrow t, \nu\right)\right|_{\Delta} ;$
$\left.[K e y] \operatorname{Sec}_{\tau}(\vec{A}, t \longrightarrow\langle t, t\rangle, \nu)\right|_{\Delta} ;$
$\left.\left[K^{2} y\right] \operatorname{Sec}_{\tau}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle \longrightarrow\left\langle t^{\prime}, t\right\rangle, \nu\right)\right|_{\Delta} ;$
$\left.\left[K^{\operatorname{Key}}\right] \operatorname{Sec}_{\tau}\left(\vec{A},\left\langle\left\langle t, t^{\prime}\right\rangle, t^{\prime \prime}\right\rangle \longleftrightarrow\left\langle t,\left\langle t^{\prime}, t^{\prime \prime}\right\rangle\right\rangle, \nu\right)\right|_{\Delta} ;$
(g) $\nu$ reveals itself:
$\left.\neg[$ Key $] \operatorname{Sec}_{\tau}(\vec{A}, \nu, \nu)\right|_{\Delta} ;$
(h) Corruption depends only on the bit string, not how it was created:
$\left.[K e y] \operatorname{Sec}_{\tau}(\vec{A}, t \longleftrightarrow \bar{t}, \nu)\right|_{\Delta} ;$
(i) Honest encryptions of $t^{\prime}$ by secure keys cannot corrupt $\nu$ :

$$
\begin{aligned}
& {\left.[K e y] \operatorname{Sec}_{\tau}\left(\vec{A}, t \xrightarrow{A \sqsubseteq \vec{A}}\left\langle t,\left\{t^{\prime}\right\}_{A}^{r}\right\rangle, \nu\right)\right|_{\Delta} ;} \\
& {\left.[K e y] \operatorname{Sec}_{\tau}\left(\vec{A}, t, \xrightarrow{A \sqsubseteq \vec{A} \wedge A^{\prime} \sqsubseteq \vec{A}}\left\langle t,\left\{t^{\prime}\right\}_{A A^{\prime}}^{r}\right\rangle, \nu\right)\right|_{\Delta} ;}
\end{aligned}
$$

$$
\begin{aligned}
& \left.\operatorname{Sec}_{\tau}\left(\vec{A}, t \xrightarrow{\operatorname{KeySec}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle, K\right) \wedge K \neq \nu}\left\langle t,\left\{t^{\prime}\right\}_{K}^{r}\right\rangle, \nu\right)\right|_{\Delta} ; \\
& \left.\operatorname{KeySec}_{\tau}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle \longrightarrow\left\langle t,\left\{t^{\prime}\right\}_{K}^{r}\right\rangle, K\right)\right|_{\Delta} ;
\end{aligned}
$$

(j) If $t^{\prime}$ does not corrupt $\nu$, then its encryption does not either:

$$
\begin{aligned}
& {\left[\left.{\text { Key }]\left.\operatorname{Sec}_{\tau}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle \longrightarrow\left\langle t,\left\{t^{\prime}\right\}_{Q}^{r}\right\rangle, \nu\right)\right|_{\Delta} ;}_{\left[\text {Key }^{\prime} S_{\text {Sec }}^{\tau}\right.}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle \longrightarrow\left\langle t,\left\{t^{\prime}\right\}_{Q Q^{\prime}}^{r}\right\rangle, \nu\right)\right|_{\Delta} ;\right.} \\
& {\left[{\text { Key }]\left.\operatorname{Sec}_{\tau}\left(\vec{A},\left\langle t, t^{\prime}, k\right\rangle \longrightarrow\left\langle t,\left\{t^{\prime}\right\}_{k}^{r}\right\rangle, \nu\right)\right|_{\Delta} ;}^{\text {; }}\right. \text {; }}
\end{aligned}
$$

(k) If ciphertexts of corrupted encryptions don't corrupt $\nu$, then the plaintext cannot either, as corrupted encryptions don't provide any secrecy:

$$
\begin{aligned}
& {\left.[K e y] \operatorname{Sec}_{\tau}\left(\vec{A},\left\langle t,\left\{t^{\prime}\right\}_{Q}^{s}\right\rangle \xrightarrow{\left.Q \mathbb{A} \vec{A} \wedge t^{\prime}\right\}_{Q}^{s} \neq \perp}\left\langle t, t^{\prime},\left\{t^{\prime}\right\}_{Q}^{s}\right\rangle, \nu\right)\right|_{\Delta} ;} \\
& {\left.[K e y] \operatorname{Sec}_{\tau}\left(\vec{A},\left\langle t,\left\{t^{\prime}\right\}_{Q Q^{\prime}}^{s}\right\rangle \xrightarrow{Q Z \vec{A} \wedge\left\{t^{\prime}\right\}_{Q Q^{\prime}}^{s} \neq \perp}\left\langle t, t^{\prime},\left\{t^{\prime}\right\}_{Q Q^{\prime}}^{s}\right\rangle, \nu\right)\right|_{\Delta} ;} \\
& {\left.[K e y] \operatorname{Sec}_{\tau}\left(\vec{A},\left\langle t,\left\{t^{\prime}\right\}_{K}^{s}, K\right\rangle \xrightarrow{\left\{t^{\prime}\right\}_{K}^{s} \neq \perp}\left\langle t, t^{\prime},\left\{t^{\prime}\right\}_{K}^{r}, K\right\rangle, \nu\right)\right|_{\Delta} ;}
\end{aligned}
$$

Remark 2.9. Key cycles. Note that this system takes into account that key cycles may corrupt security. The third item of V.j. has the condition $\operatorname{KeySec}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle, K\right)$ : even if we reveal $t^{\prime}$, that is, the attacker is free to submit it to the encryption oracle, the goodness of $K$ is maintained. In a protocol that allows key cycles, this condition cannot be proven.
(VI) Axioms for relationship between properties. The following axioms connect actions, terms and cryptographic assumptions. Please note, that for better readability, we do not put out $\left.\right|_{\Delta}$ to the axioms where $\Delta$ for the premise and for the conclusion are the same. Each axiom is limited to $\Delta$.
(1) Actions and terms. The following axioms express that terms cannot be arbitrarily generated, sent.
(a) A term cannot be sent or received or generated and then generated:
$\left(\nu \sqsubseteq t \vee\left\{t^{\prime}\right\}_{\nu}^{s} \sqsubseteq t\right)$
$\rightarrow \neg\left(Q_{2}\right.$ sends $^{i_{1}} /$ receives $^{i_{1}} /$ generates $^{i_{1}} t ; Q_{1}$ generates $\left.{ }^{i_{2}} \nu\right)$.
(b) Nothing can be generated in two different sessions or two different principals:

$$
\begin{aligned}
& \left(Q_{1} \text { generates } s_{\tau_{1}}^{i_{1}} \nu_{1} \wedge Q_{2} \text { generates } \tau_{\tau_{2}}^{i_{2}} \nu_{2} \wedge \nu_{1}=\nu_{2}\right. \\
& \left.\quad \rightarrow\left(i_{1}=i_{2} \wedge Q_{1}=Q_{2} \wedge \tau=\tau^{\prime}\right)\right) .
\end{aligned}
$$

(c) Something that was generated and then received by someone, had to be sent in the same session as it was generated, before receiving it:

$$
\begin{aligned}
& \left.\left(\left(\nu \sqsubseteq t_{2} \vee\{t\}_{\nu}^{s} \sqsubseteq t_{2}\right) \wedge Q \text { generates }^{i_{1}} \nu ; Q^{\prime} \text { receives }^{i_{2}} t_{2}\right)\right|_{\Delta} \\
& \quad \rightarrow \exists t_{1} t^{\prime} s^{\prime} \Delta^{\prime}\left(\left(\Delta ^ { \prime } \subseteq \Delta \wedge \left(\left(\nu \sqsubseteq t_{1} \vee\left\{t^{\prime}\right\}_{\nu}^{s^{\prime}} \sqsubseteq t_{1}\right)\right.\right.\right. \\
& \quad \wedge Q \text { sends }^{\left.\left.i_{1} t^{\prime} ; Q^{\prime} \text { receives }^{i_{2}} t\right)\left.\right|_{\Delta^{\prime}} ^{\prime}\right)}
\end{aligned}
$$

(d) Something that was sent by an honest agent had to be either generated by him, or received from someone else:

$$
\begin{aligned}
& \left(m \sqsubseteq t_{2} \vee\{t\}_{m}^{s} \sqsubseteq t_{2}\right) \wedge \text { A sends }{ }^{i} t_{2} \\
& \rightarrow \exists t_{1} \Delta^{\prime}\left(\Delta^{\prime} \subseteq \Delta \wedge \text { generates }^{i} m ; A \text { sends }{ }^{i} t_{2}\right. \\
& \left.\vee \vee\left(A \text { receives }^{i} t_{1} ; A \text { sends } s^{i} t_{2} \wedge m \sqsubseteq t_{1}\right)\right)\left.\right|_{\Delta} .
\end{aligned}
$$

(e) Something on which an honest action was carried out, cannot be the error $\perp$. $\left(t \sqsubseteq t^{\prime} \vee t=A\right) \wedge\left(A\right.$ sends ${ }^{i} t^{\prime} \vee$ $A$ receives ${ }^{i} t^{\prime} \vee A$ generates $\left.{ }^{i} t^{\prime}\right) \rightarrow t \neq \perp$
(f) All honest nonces and keys were sometime generated: $\exists A i \Delta\left(A\right.$ generates $\left.\left.{ }^{i} N\right|_{\Delta}\right)$
(2) Secrecy. This axiom expresses that if no send action corrupted $\nu$, then it had to remain uncorrupted. The axiom specified here is not suitable if reveal action is allowed. In that case security will hold until the reveal action (in Appendix). For $\vec{A}=\left\langle A_{1}, \ldots, A_{n}\right\rangle$ we postulate

$$
\begin{aligned}
& \left(\left[{\text { Key } \left.] \operatorname{Sec}_{\mathbf{0}}(\vec{A}, u, \nu) \wedge C[\nu] \wedge C^{\prime}[u] \wedge \nu \nsubseteq u\right)\left.\right|_{\Delta}}_{\quad \wedge[\text { Key }] \operatorname{SecSend}\left(\vec{A}, C, C^{\prime}\right)}^{\left.\quad \rightarrow[\text { Key }] \operatorname{Sec}_{\infty}(\vec{A}, u, \nu)\right|_{\Delta}}\right.\right.
\end{aligned}
$$

(3) Authentication with public key. This says that if a message of the form $\left\{t^{\prime}\right\}_{A}^{s}$ was received, and if $\left\{t^{\prime}\right\}_{A}^{s}$ does not corrupt $\nu$, but $t^{\prime}$ does, then, at least on a part of the traces (the part on which $t^{\prime}$ corrupts $\left.\nu\right),\left\{t^{\prime}\right\}_{A}^{S}$ had to be created by one of the principals in $\vec{A}$ as only they may know $\nu$. This axiom is sound as long as the public-key encryption satisfies IND-CCA security:

$$
\begin{aligned}
& \left(\left\{t^{\prime}\right\}_{A}^{s} \sqsubseteq t_{2} \wedge A \text { receives }_{\tau_{2}}^{i_{2}} t_{2} \wedge \tau \leq \tau_{2}\right. \\
& \quad \wedge\left[\text { Key }^{2} \text { Sec }\left._{\tau}\left(\vec{A},\left\langle t,\left\{t^{\prime}\right\}_{A}^{s}\right\rangle, \nu\right) \wedge \neg\left[\text { Key }^{2} \text { Sec }_{\tau}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle, \nu\right)\right)\right|_{\Delta}\right. \\
& \rightarrow \exists A^{\prime} t_{1} t^{\prime \prime} i_{1} r \tau_{1} \Delta^{\prime}\left(A^{\prime} \sqsubseteq \vec{A} \wedge \Delta^{\prime} \subseteq \Delta \wedge\left\{t^{\prime \prime}\right\}_{A}^{r} \sqsubseteq t_{1}\right. \\
& \left.\wedge \overline{\left\{t^{\prime}\right\}_{A}^{s}}=\left.\overline{\left\{t^{\prime \prime}\right\}_{A}^{r}} \wedge\left(A^{\prime} \text { sends }_{\tau_{1}}^{i_{1}} t_{1} ; \text { A receivess } \tau_{\tau_{2}}^{i_{2}} t_{2}\right)\right|_{\Delta^{\prime}}\right)
\end{aligned}
$$

(4) Authentication with long-term shared key: This axiom expresses the unforgeability (see section 3) of the shared key encryption for given plaintext. That is, if $\left\{t^{\prime}\right\}_{A B}^{r}$ was received, and if it contains a randomly generated nonce or key, then it had to be created and sent either by $A$ or $B$ :

$$
\begin{aligned}
& \left.\left(\text { A receives } \tau_{\tau_{2}}^{i_{2}} t_{2} \wedge\{t\}_{A B}^{s} \sqsubseteq t_{2} \wedge N \sqsubseteq t \vee K^{\prime} \sqsubseteq t\right)\right|_{\Delta} \\
& \quad \rightarrow \exists A^{\prime} i_{1} t_{1} t^{\prime} \Delta^{\prime}\left(\Delta^{\prime} \subseteq \Delta \wedge\left(A^{\prime}=A \vee A^{\prime}=B\right)\right. \\
& \wedge\left(A^{\prime} \text { sends }_{1}^{i_{1}} t_{1} ; A \text { receives } i_{\tau_{2}} t_{2} \wedge\left\{t^{\prime}\right\}_{A B}^{r} \sqsubseteq t_{1}\right. \\
& \left.\left.\left.\wedge \overline{\{t\}_{A B}^{s}}=\overline{\left\{t^{\prime}\right\}_{A B}^{r}}\right)\right)\left.\right|_{\Delta^{\prime}}\right)
\end{aligned}
$$

(5) Authentication with shared session key
(a) This is the same as the previous for an uncorrupted key $K$ :

$$
\begin{aligned}
& \left(\text { KeySec }_{\tau_{2}}(\vec{A}, K) \wedge A \text { receives }_{\tau_{2}}^{i_{2}} t_{2} \wedge\{t\}_{K}^{s} \sqsubseteq t_{2}\right. \\
& \left.\quad \wedge N \sqsubseteq t \vee K^{\prime} \sqsubseteq t\right)\left.\right|_{\Delta} \\
& \rightarrow \exists A^{\prime} i_{1} t_{1} t^{\prime} r \tau_{1} \Delta^{\prime}\left(\Delta^{\prime} \subseteq \Delta \wedge A^{\prime} \sqsubseteq \vec{A}\right. \\
& \wedge\left(A^{\prime} \text { sends }_{\tau_{1}}^{i_{1}} t_{1} ; A \text { receives } \tau_{\tau_{2}}^{i_{2}} t_{2}\right. \\
& \left.\left.\quad \wedge\left\{t^{\prime}\right\}_{K}^{r} \sqsubseteq t_{1} \wedge\{t\}_{K}^{s}=\overline{\left\{t^{\prime}\right\}_{K}^{r}}\right)\left.\right|_{\Delta^{\prime}}\right)
\end{aligned}
$$

(b) This axiom is similar to the one for public key. It says that if $\left\{t^{\prime}\right\}_{K}^{s}$ does not corrupt $\nu$ but $t^{\prime}$ does, then, at least on a part of the traces, $\left\{t^{\prime}\right\}_{K}^{s}$ had to be created by one of the principals in $\vec{A}$. Note, that this axiom does not require that $K$ is uncorrupted. Nevertheless, soundness needs the IND-CCA property of the encryption.

$$
\begin{aligned}
& \left(A \sqsubseteq \vec{A} \wedge\left\{t^{\prime}\right\}_{K}^{s} \sqsubseteq t_{2} \wedge \text { A receives }{ }_{\tau_{2}}^{i_{2}} t_{2} \wedge\right. \\
& \tau \leq \tau_{2} \wedge\left[K_{e y}\right] \operatorname{Sec}_{\tau}\left(\vec{A},\left\langle t,\left\{t^{\prime}\right\}_{K}^{s}\right\rangle, \nu\right) \wedge \\
& \left.\neg\left[K^{\operatorname{Key}]} \operatorname{Sec}_{\tau}\left(\vec{A},\left\langle t, t^{\prime}\right\rangle, \nu\right)\right)\right)\left.\right|_{\Delta} \\
& \rightarrow \exists A^{\prime} i_{1} t_{1} t^{\prime \prime} r \tau_{1} \Delta^{\prime}\left(A ^ { \prime } \sqsubseteq \vec { A } \wedge \Delta ^ { \prime } \subseteq \Delta \wedge \left(\left\{t^{\prime \prime}\right\}_{K}^{r} \sqsubseteq t_{1}\right.\right. \\
& \left.\left.\wedge \overline{\{t\}_{K}^{s}}=\overline{\left\{t^{\prime \prime}\right\}_{K}^{r}} \wedge A^{\prime} \operatorname{sends}_{\tau_{1}}^{i_{1}} t_{1} ; A \text { receives } s_{\tau_{2}}^{i_{2}} t_{2}\right)\left.\right|_{\Delta^{\prime}}\right)
\end{aligned}
$$

Let the presented theory be called $\mathcal{T}$. Let $\mathcal{T}^{\prime}$ be the theory where all elements of sort event are replaced by $\mathbf{D}$, which practically means deleting all items of this sorts from every formulas. Then, $\mathcal{T}^{\prime}$ is of course not sound, but it can be used to prove the agreement and authentication formulas as we have the following theorem:

Theorem 2.10. If $\varphi$ is a formula without $\left.\right|_{\Delta}$ satisfying $\forall \Delta^{\prime}\left(\left.\left.\Delta^{\prime} \subseteq \Delta \wedge \varphi\right|_{\Delta} \rightarrow \varphi\right|_{\Delta^{\prime}}\right)$, that is, $\varphi$ is restrictable, and $\varphi^{\prime}$ is both restrictrable and extendable, that is, $\forall \Delta^{\prime}\left(\Delta^{\prime} \subseteq\right.$ $\left.\left.\left.\Delta \wedge \varphi^{\prime}\right|_{\Delta} \rightarrow \varphi^{\prime}\right|_{\Delta^{\prime}}\right)$ and $\forall \Delta_{1} \Delta_{2}\left(\left.\left.\varphi^{\prime}\right|_{\Delta_{1}} \wedge \varphi^{\prime}\right|_{\Delta_{2}} \rightarrow\right.$ $\left.\left.\varphi^{\prime}\right|_{\Delta_{1} \cup \Delta_{2}}\right)$, then $\varphi \vdash_{\mathcal{T}} \varphi^{\prime}$ if and only if $\varphi \vdash_{\mathcal{T}^{\prime}} \varphi^{\prime}$.

Since the premisses of agreement and authentication properties are restrictable, we don't have to consider $\Delta$ 's when we prove them. The proof of this theorem uses the fact that all of our axioms have the following pattern: If some formula is true on a $\Delta$, another is true on a $\Delta^{\prime} \subseteq \Delta$. So all derived formulas have this form as well, and then axiom III.3. proves the theorem.

## 3. Computational Assumptions

We need to fix a couple of computational operations: Pairing is an injective pairing function $[\cdot, \cdot]$ : strings $\times$ strings $\rightarrow$ strings. We assume that the length of the pair only depends on the lengths of its inputs. We assume that the length of the ciphertext of encryptions depends only on the length of the plaintext. Honest nonces all have identical lengths as well as honest keys.

In this paper, we assume that the encryption schemes satisfie adaptive chosen ciphertext security (IND-CCA) both in case of asymmetric and symmetric encryptions. For the definition of IND-CCA security, we refer the reader to [3].
Unforgeability. In addition to IND-CCA security, we require that the symmetric encryption satisfies an unforgeability condition. Clearly, agreement in the symmetric NS protocol cannot possibly be proven from the initiator's view, if the encryption $\left\{n_{3}\right\}_{K}^{s}$ can be forged. In that case, the initiator cannot be sure where this message came from. To prevent this, we need to require the so-called existential unforgeability (see [15]), saying that no encryption for a given secret key can be forged. In this case however, an encryption cannot possibly be confused with another encryption, so there is unarbitrary parsing for this encryption. We would like to emphasize though that our method works even when parsing in general may be arbitrary. So we we do not assume this property (but they can easily be modified for it), and we don't prove agreement for sNS in initiator's view. Instead, we assume random plaintext unforgeability (see again [15]) but allowing decryption oracle for the attacker. In this case, the attacker has to create a ciphertext for given, random plaintext while allowed to quarry encryption and decryption oracles. The authenticity of $\left\{n_{3}\right\}_{K}^{s}$ cannot be ensured, but of all other messages can, so we can prove agreement from the responder's view.
Theorem 3.1. With these computational assumptions, the above set of theorems is computationally sound with respect to the computational structures described in the Appendix.

## 4. Amended Needham-Schroeder Authentication and Agreement

In this section, we would like to illustrate how the proof works on the Amended Needham-Schroeder protocol introduced in Example 2.5. The agreement - authentication property was discussed earlier, it is expressed by the sequent (1). That is, given that the responder finished its role, and that the trusted party and the initiator follow their roles honestly, we can conclude that the initiator and the trusted party also finish their roles and the nonces and keys match. This is proven via first proving KeySecSend:

$$
\begin{aligned}
& F O L L\left(\operatorname{Init}_{s N S}^{A}\right) \wedge F O L L\left(\operatorname{Resp}_{s N S}^{B}\right) \wedge F O L L\left(\operatorname{Trust}_{s N S}^{T}\right) \\
& \vdash \operatorname{KeySecSend}\left(\langle A, B, T\rangle, C, C^{\prime}\right) .
\end{aligned}
$$

This amounts to proving that

```
\(F O L L\left(\right.\) Init \(\left._{s N S}^{A}\right) \wedge F O L L\left(\right.\) Resp \(\left._{s N S}^{B}\right) \wedge F O L L\left(\right.\) Trust \(\left._{s N S}^{T}\right)\)
\(\wedge C[K] \wedge C^{\prime}[u] \wedge K \nsubseteq u \wedge A^{\prime} \sqsubseteq\langle A, B, T\rangle \wedge A^{\prime} \operatorname{sends}_{\tau}^{i} t\)
\(\wedge \forall u^{\prime}\left(C^{\prime}\left[u^{\prime}\right] \wedge K \nsubseteq u^{\prime} \rightarrow \operatorname{KeySec}_{\tau}\left(\langle A, B, T\rangle, u^{\prime}, K\right)\right)\)
\(\vdash \operatorname{KeySec}_{\tau}(\langle A, B, T\rangle,\langle t, u\rangle, K)\).
\(C\) and \(C^{\prime}\) were defined in Example 2.8.
For limited space, we just indicate the idea of the proof. By Theorem 2.10, we don't need to use \(\Delta\) 's in the proof.
Proof sketch of (4). In the premise, the possibilities of what \(A^{\prime}\) sends \({ }_{\tau}^{i} t\) can be is limited, as \(A^{\prime}\) may only be either \(T, A\), or \(B\), and they all follow the protocol roles honestly. So the possibilities are the following:
1.) If \(A^{\prime}=T\), then for some \(n_{1}^{\prime}, n_{2}^{\prime}, Q_{1}^{\prime}, Q_{2}^{\prime}, K^{\prime}, r_{1}, r_{2}^{\prime}\),
\[
t=\left\{n_{2}^{\prime}, Q_{2}^{\prime}, K^{\prime},\left\{K^{\prime}, n_{1}^{\prime}, Q_{1}^{\prime}\right\}_{Q_{2}^{\prime} T}^{r_{2}^{\prime}}\right\}_{Q_{1}^{\prime} T}^{r_{3}^{\prime}}
\]
2.) If \(A^{\prime}=B\) then for some \(Q_{1}, N_{1}, N_{3}, k, r_{1}, r_{4}\),
\[
t=\left\{Q_{1}, N_{1}\right\}_{B T}^{r_{1}} \vee t=\left\{N_{3}\right\}_{k}^{r_{4}} .
\]
3.) If \(A^{\prime}=A\), then for some \(Q_{2}, N_{2}, m_{1}, m_{2}, n_{3}, r_{5}, k\),
\(t=A \vee t=\left\langle A, Q_{2}, N_{2}, m_{1}\right\rangle \vee t=m_{2} \vee t=\left\{n_{3}, A\right\}_{k}^{r_{5}}\).
In the proof, we go through all these cases, and show that \(\operatorname{KeySec}_{\tau}(\langle A, B, T\rangle,\langle t, u\rangle, K)\) holds. Here there is no room to do that, we only show one specific case, when
3.3.) \(t=m_{2}\). So we have to show
\[
\begin{equation*}
\operatorname{KeySec}_{\tau}\left(\langle A, B, T\rangle,\left\langle m_{2}, u\right\rangle, K\right), \tag{5}
\end{equation*}
\]
which means tracking down where \(m_{2}\) came from, what it is equal to, and so show that it does not corrupt the security of \(K\). Since \(A\) follows his role honestly, that is \(F O L L\left(\right.\) Init \(\left._{\mathrm{sNS}}^{A}\right)\) holds, we have
\[
\begin{equation*}
\text { A receives } \tau_{\tau^{\prime}}^{i}\left\{N_{2}, Q_{2}, k, m_{2}\right\}_{A T}^{s_{3}} ; A \operatorname{sends}_{\tau}^{i} m_{2} \tag{6}
\end{equation*}
\]

That is, \(A\) received \(m_{2}\) in a secure encryption from the trusted party \(T\). Axiom VI.4. tells us, that the long term
shared keys of honest participants guarantee authentication, that is, the message had to come from \(A\) or \(T\) :
\[
\begin{align*}
& \exists A^{\prime \prime} i^{\prime \prime} t_{1} t^{\prime}\left(\left(A^{\prime \prime}=A \vee A^{\prime \prime}=T\right) \wedge\left\{t^{\prime}\right\}_{A T}^{r} \sqsubseteq t_{1}\right. \\
& \wedge \overline{\left\{N_{2}, Q_{2}, k, m_{2}\right\}_{A T}^{s_{3}}}=\overline{\left\{t^{\prime}\right\}_{A T}^{r}}  \tag{7}\\
& \left.\left.\wedge A^{\prime \prime} \operatorname{sends}_{\tau_{1}}^{i^{\prime \prime}} t_{1} ; A \text { receives } \tau_{\tau^{\prime}}^{i}\left(N_{2}, Q_{2}, k, m_{2}\right\}_{A T}^{s_{3}}\right)\right)
\end{align*}
\]
and the third conjunct implies that
\[
\begin{equation*}
\overline{\left\langle N_{2}, Q_{2}, k, m_{2}\right\rangle}=\overline{t^{\prime}} \tag{8}
\end{equation*}
\]

A sends \({ }^{i^{\prime \prime}} t_{1} \wedge\left\{t^{\prime}\right\}_{A T}^{r} \sqsubseteq t_{1}\) is not possible because of \(F O L L\left(\right.\) Init \(\left._{s N S}^{A}\right)\) and term axioms ( \(A\) never sends out a message using his shared key with \(T\) ). So \(A^{\prime \prime}=T\). But \(T\) sends \({ }^{i^{\prime \prime}} t_{1}\) and \(F O L L\left(\operatorname{Trust}_{s N S}^{T}\right)\) imply that \(t_{1}=\) \(\left\{n_{2}, Q_{2}^{\prime}, K^{\prime},\left\{K^{\prime}, n_{1}, Q_{1}^{\prime}\right\}_{Q_{2}^{\prime} T}^{r_{2}}\right\}_{Q_{1}^{\prime} T}^{r_{3}}\). Then \(\left\{t^{\prime}\right\}_{A T}^{r} \sqsubseteq t_{1}\) implies with term axioms that
\[
\begin{aligned}
& \left\{t^{\prime}\right\}_{A T}^{r}=\left\{K^{\prime}, n_{1}, Q_{1}^{\prime}\right\}_{Q_{2}^{\prime} T}^{r_{2}} \vee \\
& \left\{t^{\prime}\right\}_{A T}^{r}=\left\{n_{2}, Q_{2}^{\prime}, K^{\prime},\left\{K^{\prime}, n_{1}, Q_{1}^{\prime}\right\}_{Q_{2}^{\prime} T}^{r_{2}}\right\}_{Q_{1}^{\prime} T}^{r_{3}}
\end{aligned}
\]
3.3.1.) If \(\left\{t^{\prime}\right\}_{A T}^{r}=\left\{K^{\prime}, n_{1}, Q_{1}^{\prime}\right\}_{Q_{2}^{\prime} T}^{r_{2}}\), then \(Q_{2}^{\prime}=A\), and
\[
\begin{equation*}
t^{\prime}=\left\langle K^{\prime}, n_{1}, Q_{1}^{\prime}\right\rangle \tag{9}
\end{equation*}
\]

By (8) and (9), \(\overline{\left\langle N_{2}, Q_{2}, k, m_{2}\right\rangle}=\overline{\left\langle K^{\prime}, n_{1}, Q_{1}^{\prime}\right\rangle}\), that is, by our convention, \(\overline{\left\langle\left\langle\left\langle N_{2}, Q_{2}\right\rangle, k\right\rangle, m_{2}\right\rangle}=\overline{\left\langle\left\langle K^{\prime}, n_{1}\right\rangle, Q_{1}^{\prime}\right\rangle}\), which, by term axioms, implies that \(\overline{\left\langle N_{2}, Q_{2}\right\rangle}=K^{\prime}\), which results in a contradiction, because we would have

True \(\equiv \operatorname{Sec}_{\mathbf{0}}\left(\vec{A}, K^{\prime}, N_{2}\right) \leftrightarrow \operatorname{Sec}_{\mathbf{0}}\left(\vec{A},\left\langle N_{2}, Q_{2}\right\rangle, N_{2}\right) \equiv\) False.
So \(\left\{t^{\prime}\right\}_{A T}^{r} \neq\left\{K^{\prime}, n_{1}, Q_{1}^{\prime}\right\}_{Q_{2}^{\prime} T}^{r_{2}}\).
3.3.2.) If \(\left\{t^{\prime}\right\}_{A T}^{r}=\left\{n_{2}, Q_{2}^{\prime}, K^{\prime},\left\{K^{\prime}, n_{1}, Q_{1}^{\prime}\right\}_{Q_{2}^{\prime} T}^{r_{2}}\right\}_{Q_{1}^{\prime} T}^{r_{3}}\), then by term axioms, \(Q_{1}^{\prime}=A\), and
\[
\begin{equation*}
t^{\prime}=\left\langle n_{2}, Q_{2}^{\prime}, K^{\prime},\left\{K^{\prime}, n_{1}, A\right\}_{Q_{2}^{\prime} T}^{r_{2}}\right\rangle \tag{10}
\end{equation*}
\]

By (8) and (10), \(\overline{\left\langle n_{2}, Q_{2}^{\prime}, K^{\prime},\left\{K^{\prime}, n_{1}, A\right\}_{Q_{2}^{\prime} T}^{r_{2}}\right\rangle}=\) \(\overline{\left\langle N_{2}, Q_{2}, k, m_{2}\right\rangle}\), and by term axioms,
\(N_{2}=n_{2} \wedge Q_{2}=Q_{2}^{\prime} \wedge K^{\prime}=k \wedge m_{2}=\overline{\left\{K^{\prime}, n_{1}, A\right\}_{Q_{2}^{\prime} T}^{r_{2}}}\).
So we know that \(m_{2}=\overline{\left\{K^{\prime}, n_{1}, A\right\}_{Q_{2}^{\prime} T}^{r_{2}}}\), and so to complete the proof of (5), by axiom V.h., we have to show that
\[
\operatorname{KeySec}_{\tau}\left(\langle A, B, T\rangle,\left\langle\left\{K^{\prime}, n_{1}, A\right\}_{Q_{2}^{\prime} T}^{r_{2}}, u\right\rangle, K\right)
\]

From (6), (7), and that \(T\) follows the protocol,
\(T\) receives \({\underset{\tau_{1}^{\prime \prime}}{i^{\prime \prime}}}_{i^{\prime}}\left\langle A, Q_{2}, N_{2},\left\{A, n_{1}\right\}_{Q_{2} T}\right\rangle ; T\) generates \({ }_{\tau_{1}^{\prime}}^{i^{\prime \prime}} K^{\prime} ;\)
\(T\) sends \({\underset{\tau_{1}}{i^{\prime \prime}}\left\{N_{2}, Q_{2}, K^{\prime},\left\{K^{\prime}, n_{1}, A\right\}_{Q_{2} T}^{r_{2}}\right\}_{A T}^{r_{3}} ; ~ ; ~}_{\text {; }}\)
\(A\) receives \(_{\tau^{\prime}}^{i}\left\{N_{2}, Q_{2}, K^{\prime}, m_{2}\right\}_{A T}^{s_{3}} ; A\) sends \(_{\tau}^{i} m_{2}\)
follows with \(k=K^{\prime}\) and \(m_{2}=\overline{\left\{K^{\prime}, n_{1}, A\right\}_{Q_{2} T}^{r_{2}}}\), where \(Q_{2} \neq T\).
3.3.2.1.) If \(Q_{2} \neq B \wedge Q_{2} \neq A\), then \(K^{\prime}\) does not satisfy \(C\), so \(K \neq K^{\prime}\). But \(T\) generates \({ }^{i^{\prime \prime}} K^{\prime}\), so \(\left\langle K^{\prime}, u\right\rangle\) satisfies \(C^{\prime}\), and therefore, by the premise of SecSend,
\[
\operatorname{KeySec}_{\tau}\left(\langle A, B, T\rangle,\left\langle K^{\prime}, u\right\rangle, K\right) .
\]

Since \(\tau_{1}^{\prime \prime}<\tau\), and \(T\) receives \(\tau_{\tau_{1}^{\prime \prime}}^{i^{\prime \prime}}\left\langle A, Q_{2}, N_{2},\left\{A, n_{1}\right\}_{Q_{2} T}\right\rangle\), by axiom V.c., we have with \(\vec{A}=\langle A, B, T\rangle\),
\[
\operatorname{KeySec}_{\tau}\left(\vec{A},\left\langle\left\langle A, Q_{2}, N_{2},\left\{A, n_{1}\right\}_{Q_{2} T}\right\rangle, K^{\prime}, u\right\rangle, K\right)
\]
by this and ax. V.f., \(\operatorname{KeySec}_{\tau}\left(\vec{A},\left\langle\left\{A, n_{1}\right\}_{Q_{2} T}, K^{\prime}, u\right\rangle, K\right)\), which in turn implies by axiom V.k., that \(\operatorname{KeySec}_{\tau}\left(\vec{A},\left\langle A, n_{1},\left\{A, n_{1}\right\}_{Q_{2} T}, K^{\prime}, u\right\rangle, K\right)\). By IV.f again, \(\operatorname{KeySec}_{\tau}\left(\vec{A},\left\langle K^{\prime}, n_{1}, A, u\right\rangle, K\right)\). So, by axiom V.j.,
\[
\operatorname{KeySec}_{\tau}\left(\langle A, B, T\rangle,\left\langle\left\{K^{\prime}, n_{1}, A\right\}_{Q_{2} T}^{r_{2}}, u\right\rangle, K\right) .
\]
\[
\begin{aligned}
& \text { 3.3.2.2.) If } Q_{2}=B \vee Q_{2}=A \text {, then by Ax V.i, } \\
& \text { KeySec }_{\tau}\left(\langle A, B, T\rangle,\left\langle\left\{K^{\prime}, n_{1}, A\right\}_{Q_{2}^{\prime} T}^{r_{2}}, u\right\rangle, K\right),
\end{aligned}
\]
so \(\operatorname{KeySec}_{\tau}\left(\langle A, B, T\rangle,\left\langle m_{2}, u\right\rangle, K\right)\) was shown in all cases.
In a similar manner, we can prove that none of the other send actions of \(A, B\) and \(T\) in any session corrupt \(K\).
Proof sketch of (1). The premise of this formula, namely, the responder's role implies \(B\) receives \({ }^{i^{i}}\left\{k, N_{1}, A\right\}_{B T}^{s_{2}}\). The same way as we proved (11), we can show that \(k\) had to be generated and sent by \(T\). So there is a \(K=k\), with
\(T\) generates \({ }^{i^{\prime \prime}} K ; T\) sends \(s^{i{ }^{\prime \prime}}\left\{n_{2}, B, K,\left\{K, N_{1}, A\right\}_{B T}^{s_{2}}\right\}_{A T}^{r_{3}}\); \(B\) receives \(^{i^{i}}\left\{K, N_{1}, A\right\}_{B T}^{s_{2}} ; B\) receives \(^{i^{\prime}}\left\{N_{3}, A\right\}_{K}^{s_{5}}\).
Therefore, we have
\[
\exists i^{\prime \prime} n_{2} s_{1} r_{2} r_{3} \operatorname{Trust} t_{s N S}^{T}\left[T, i^{\prime \prime}, A, B, k, N_{1}, n_{2}, s_{1}, r_{2}, r_{3}\right] .
\]

Also, \(K\) satisfies \(C\). Hence, since we showed KeySecSend, by axiom VI.2. we have \(\mathrm{KeySec}_{\infty}(\langle A, B, T\rangle, K)\). Then,
\[
\begin{aligned}
& \exists A^{\prime} i_{1} t_{1} t^{\prime} r\left(A^{\prime} \sqsubseteq\langle A, B, T\rangle \wedge\left\{t^{\prime}\right\}_{K}^{r} \sqsubseteq t_{1} \wedge \overline{\left\{N_{3}, A\right\}_{K}^{s_{5}}}=\overline{\left\{t^{\prime}\right\}_{K}^{r}}\right. \\
& \left.\wedge A^{\prime} \text { sends }^{i_{1}} t_{1} ; B \text { receives }{ }^{i^{\prime}}\left\{N_{3}, A\right\}_{K}^{s_{5}}\right) .
\end{aligned}
\]

By Axiom VI.5.a.
1.) \(A^{\prime}=T\) is not possible, because of \(F O L L\left(\right.\) Trust \(\left._{s N S}^{T}\right): T\) never encrypts with session key.
2.) If \(A^{\prime}=B\), then by \(\operatorname{FOLL}\left(\operatorname{Resp}_{s N S}^{B}\right), t_{1}=\left\{N_{3}^{\prime}\right\}_{K}^{r_{4}^{\prime}}\) and \(\overline{\left\{N_{3}^{\prime}\right\}_{K}^{r_{4}^{\prime}}}=\overline{\left\{N_{3}, A\right\}_{K}^{s_{5}}}\), therefore \(N_{3}^{\prime}=\overline{\left\langle N_{3}, A\right\rangle}\), which is not possible by Axiom IV.2.f., if \(N_{3} \neq N_{3}^{\prime}\), and not possible by our additional assumption in Example 2.5 if \(N_{3}=N_{3}^{\prime}\). So \(A^{\prime} \neq B\).
3.) If \(A^{\prime}=A\), then by \(F O L L\left(I n i t_{\mathrm{sNS}}^{A}\right), t_{1}=\left\{n_{3}, A\right\}_{K}^{r_{5}}\), and by term axioms, \(n_{3}=N_{3}\), so
\[
\exists i r_{5}\left(A \text { sends }^{i}\left\{N_{3}, A\right\}_{K}^{r_{5}^{5}} ; B \text { receives }^{i^{\prime}}\left\{N_{3}, A\right\}_{K}^{s_{5}}\right) .
\]

So by \(F O L L\left(\right.\) Init \(\left._{\mathrm{sNS}}^{A}\right)\),
\[
\begin{aligned}
& \exists i Q_{2} m_{1} m_{2} N_{2} s_{3} s_{4} r_{5} \\
& \text { Init }_{\mathrm{sNS}}^{A}\left[T, A, i, Q_{2}, m_{1}, m_{2}, k, N_{2}, N_{3}, s_{3}, s_{4}, r_{5}\right] .
\end{aligned}
\]

In particular, \(\quad A\) receives \({ }^{i}\left\{N_{2}, Q_{2}, K, m_{2}\right\}_{A T}^{r_{3}}\); \(A\) sends \({ }^{i} m_{2} ; \quad A\) receives \({ }^{i}\left\{N_{3}\right\}_{K}^{s_{4}} ; \quad A\) sends \({ }^{i}\left\{N_{3}, A\right\}_{K}^{s_{5}}\). Just as the way we received (11), we have that
\[
\begin{aligned}
& \exists i^{\prime \prime \prime} K n_{1}^{\prime} r_{1}^{\prime} r_{3}^{\prime}\left(m_{2}=\overline{\left\{K, n_{1}^{\prime}, A\right\}_{Q_{2} T}^{r_{2}^{\prime}}} \wedge\right. \\
& T \text { sends } s^{\prime \prime \prime}\left\{N_{2}, Q_{2}, K,\left\{K, n_{1}^{\prime}, A\right\}_{Q_{2} T}^{r_{2}^{\prime}}\right\}_{A T}^{r_{3}^{\prime}} ; \\
& \text { A receives }\left\{N_{2}, Q_{2}, K, m_{2}\right\}_{A T}^{r_{A}} ; A \text { sends }^{i} m_{2} ; \\
& \text { A receives } \left.\left\{N_{3}\right\}_{K}^{s_{4}} ; A \text { sends }^{2}\left\{N_{3}, A\right\}_{K}^{s_{5}}\right) .
\end{aligned}
\]

But since by \(F O L L\left(\right.\) Trust \(\left._{\mathrm{sNS}}^{T}\right), T\) generates \({ }^{i^{\prime \prime}} K \wedge\) \(T\) generates \({ }^{i^{\prime \prime \prime}} K\), according to axiom VI.1.b, we have \(i^{\prime \prime}=i^{\prime \prime \prime}\). Then by \(F O L L\left(\operatorname{Trust}_{\mathrm{sNS}}^{T}\right)\),
\(\left\{N_{2}, Q_{2}, K,\left\{K, n_{1}^{\prime}, A\right\}_{Q_{2}}^{r_{2}^{\prime}}\right\}^{r_{3 T}}=\left\{n_{2}, B, K,\left\{K, N_{1}, A\right\}_{B T}^{s_{2}}\right\}_{A T}^{r_{3}}\)
and term axioms, \(n_{1}^{\prime}=N_{1}, n_{2}=N_{2}, Q_{2}=B\). Therefore,
\(\exists i i^{\prime \prime} m_{1} N_{2} s_{1} r_{2} r_{3} s_{3} s_{4} r_{5}\)
\(\left(\right.\) Init \(_{\mathrm{sNS}}^{A}\left[A, T, i, B,, m_{1}, m_{2} / \overline{\left\{k, N_{1}, A\right\}_{B T}^{r_{2}}}, k, N_{2}, N_{3}, s_{3}, s_{4}, r_{5}\right]\) \(\left.\wedge \operatorname{Trust}_{s N S}^{T}\left[T, i^{\prime \prime}, A, B, k, N_{1}, N_{2}, s_{1}, r_{2}, r_{3}\right]\right)\).

\section*{5. Discussion}

Other results. We have also been able to prove agreement and authentication from the initiator's view of the sNS protocol when the axioms are modified for existential unforgeability. With the current set of axioms, we have proven agreement and authentication from both responder's and initiator's view.
Tuples. Note, that according to our choice, tuples of messages are created via pairings from left to right. If this convention is changed, the proofs have to be changed as well. There is no a priori guarantee that bracketing in a different way will not result in new type-flaw attacks.
Type flaw attacks. In the proof, we needed the additional axiom that \(\overline{\left\langle N_{3}, A\right\rangle} \neq N_{3}\). The assumptions that we presented for the computational pairing in fact prevent this (because of the length preservation and invertability, the left must be longer), but we did not include this in the set of axioms, as with length-hiding encryption, this assumption on the pairing is not needed. Allowing \(\overline{\left\langle N_{3}, A\right\rangle}=N_{3}\), there is an attack.

Honest names were assumed to be generated honestly, so this analysis does not account for attacks that use incorrectly assigned honest names. If we want to allow the possibility of such type-flaw attacks (see [5]), then we have to remove some of the term axioms from III.2.f and III.1.e, and do the proofs without them.

In the course of the proof on NSL protocol, we also need an additional assumption, namely, \(\overline{\langle n, Q\rangle} \neq N\). This is also prevented by the length assumption as long as malicious nonces must have fixed length too, and so introducing a new type, nonce for possibly malicious nonces, this assumption makes computational sense. Without this assumption however, there is an attack:

A type flaw attack on NSL. Take a \(Q\) such that for any value of \(N\), there is an \(n\) such that \(\overline{\langle n, A\rangle}=N\). Catch \(\left\{N_{2}\right\}_{B}\) and start a new session with \(B\) with this message. \(B\) will think he received \(\{n, Q\}_{B}\), and will reveal \(n\) to \(Q\) in his response. So \(Q\) learns \(N_{2}\).
Long-term keys. Observe, that in the current paper we assume that the long-term keys were honestly generated, and were successfully distributed earlier, after which they are not being sent around. This analysis cannot account for attacks that assume otherwise, for example, assume previously corrupted but replaced long-term keys.

\section*{6. Conclusions and future work}

We have presented a relatively simple first-order proof system to analyze secrecy, agreement and authentication of protocols. Despite its simplicity, it takes care of key cycles, type-flaw issues and commitment problem. No idealizations are required for computational soundness. We have presented a theorem that tells that for the aimed properties, proof within a simpler (not sound) system is sufficient.

For future work, we are planning to introduce some lemmas that follow from the axioms to make the proofs simpler. We also plan to verify additional protocols. We want to introduce the possibility of multiple long term keys to be able to handle corrupted, replaced long term keys.

\section*{A. Computational semantics}

\section*{A.1. Elements of the computational execution}

In this paper, there is no room for providing a detailed description of the semantics, so we briefly mention the assumptions that we need for computational soundness. We write a bit more about the semantics in the appendix.

First, we would like to remind the reader, that the fundamental objects of the computational world are bit strings, strings \(=\{0,1\}^{*}\), and - as the algorithms we consider are probabilistic - random variables of bit strings. Furthermore, hardness of computation is modeled by complexity theory, hence a size parameter, which is called security parameter in the context of cryptography is given as input to all algorithms considered here. Consequently, the probability fields and random variables resulting from the executions of the probabilistic algorithms are indexed by the security parameter. As usual, the security parameter is a natural number \(\eta \in \mathbb{N}\), which, as an input of the algorithms, is represented as an \(\eta\) long string of 1 's.
Definition A. 1 (Negligible Function). A function \(f: \mathbb{N} \rightarrow\) \(\mathbb{R}\) is said to be negligible, if for any \(c>0\), there is an \(n_{c} \in\) \(\mathbb{N}\) such that \(|f(\eta)| \leq \eta^{-c}\) whenever \(\eta \geq n_{c}\).

Pairing is an injective pairing function \([\cdot, \cdot]\) : strings \(\times\) strings \(\rightarrow\) strings. We assume that the length of the pair only depends on the lengths of its inputs. An asymmetric encryption scheme is a triple of algorithms \(\left(\mathcal{K}_{a}, \mathcal{E}_{a}, \mathcal{D}_{a}\right)\) with probabilistic key generation \(\mathcal{K}_{a}\), probabilistic encryption \(\mathcal{E}_{a}\) and deterministic decryption \(\mathcal{D}_{a}\); the key generation on input \(\eta\) outputs a random encryption-key decryption-key pair. \(\mathcal{E}_{a}\) is also assumed to be probabilistic, that is, in addition to the plaintext and key, it also takes a random seed as input. A symmetric encryption scheme is a triple of algorithms \(\left(\mathcal{K}_{s}, \mathcal{E}_{s}, \mathcal{D}_{s}\right)\) with probabilistic key generation \(\mathcal{K}_{s}\), probabilistic encryption \(\mathcal{E}_{s}\) and deterministic decryption \(\mathcal{D}_{s}\); the key generation on input \(\eta\) outputs a single key, used both for encryption and decryption. We assume that the length of the ciphertext depends only on the length of the plaintext.

\section*{A.2. Computational model}

A computational model is generated the following way: We consider all protocols for which the roles can be described by the language that we gave. In particular, the protocol may only contain generation of nonces, keys, symmetric and asymmetric encryptions, decryption, creation of pairs and taking them apart. We don't allow the honest participants to send their secret keys of public-key encryption, neither long term shared keys. Further, we assume that the encryptions are IND-CCA secure, and, in addition, the symmetric encryption is unforgeable. We also assume that longterm keys (public and shared) of honest parties are all generated honestly, as well as the honest parties' names. We assume that the length of encryptions and pairings depend only on the lengths of their inputs. All algorithms are assumed to be probabilistic polynomial time in the security parameter. An execution of a protocol in a malicious environment is defined by a set of honest PPT principals trying to execute the protocol, an unlimited number of possible
other PPT principals acting arbitrarily, and a PPT adversary, who totally controls the communication between the parties (everything is sent through the adversary), and an initialization generating the long-term keys, fixing the names etc. The principals and the adversary can be represented as Turing machines, or, more conveniently, probabilistic random access machines. Unlimited number of parallel sessions are allowed. An execution is denoted by \(\mathcal{X}\).

For each security parameter \(\eta\), an execution determines a tree structure of the outcomes of the underlying subsequent coin tosses. We call this tree of coin tosses. The set of the branches of this tree, \(\Omega_{\mathcal{X}}^{\eta}\), is the underlying probability field (with a sigma algebra structure that we don't detail here). The elements, \(\omega\) are the branches of coin tosses, when all tosses are fixed. For a time \(t\) natural number \((t, \omega)\) determines the configuration of the execution \(\xi(t, \omega)\) uniquely. Each pair of execution \(\mathcal{X}\) together with a non-negligible sequence of subsets \(\mathfrak{D}=\left(\mathfrak{D}^{\eta}\right)_{\eta \in \mathbb{N}}\) (with \(\mathfrak{D}^{\eta} \subseteq \Omega_{\mathcal{X}}^{\eta}\) ) determines a model, \(\mathcal{M}_{\mathcal{X}, \mathfrak{D}}\).

The domains of interpretations of the different sorts are given the following way:
- event: \(\Phi(\Delta)\) is a sequence of sets \(\Phi(\Delta)^{\eta} \subseteq \mathfrak{D}^{\eta}\) and the probabilities of \(\Phi(\Delta)^{\eta}\) give a non-negligible function in \(\eta\).
- timesection: \(\Phi(\tau)\) is a sequence of sections of the execution trees \(\Phi(\tau)^{\eta}: \mathfrak{D}^{\eta} \rightarrow \mathbb{N}\) such that there is a polynomial time algorithm such that for any \(t \in \mathbb{N}\) and \(\omega \in \mathfrak{D}^{\eta}\), it can determine whether \(t\) equals \(\Phi(\tau)^{\eta}(\omega)\) or not based on \(\xi(1, \omega), \ldots, \xi(t, \omega)\).
- bitstring: \(\Phi(m)\) is a sequences of random variables such that \(\Phi(m)^{\eta}: \mathfrak{D}^{\eta} \rightarrow\{0,1\}^{*} \cup\{\perp\}\).
- bittree: \(\Phi(t)\) is a labeled ordered finite tree with an element of the interpretation domain of sort bitstring on each leaf and one of the function symbols Pair, LPKEnc, LSKEnc, SKEnc on each of the internal nodes. The child nodes have to match the arities of the function symbols. Such an element looks exactly the same as the tree in Figure 1, except that the leafs are labelled with sequences of random variables.
- hname is the sort of the names of honest (uncorrupted) principals (we don't model dynamic corruption here).
- name represent principals in general. They have to be fixed before the run of the protocol, their public keys and long term shared keys also fixed in advance. Their keys do not have to be correctly generated. Any principal's name may vary with the security parameter.
- hnonce means honest nonces, that is, ones that are honestly generated by some principal, with the correct
distribution and independently of everything that happened before. The distribution of nonces change with the security parameter, namely, become longer
- hkey means honest shared keys, that is, ones that are honestly generated by some principal (usually a trusted party), with the correct distribution and independently of everything that happened before. Clearly, they depend on the security parameter.
- hseed represent honestly generated random inputs of encryptions. Also depends on the security parameter.
- sessionid represents the session id's that keep track of the principals' sessions. May also depend on the security parameter.

Let \(\Phi(T)\) denote the interpretation of a term. For any variable, \(t, \Phi(t)\) is an element in one of the above domains, depending on the sort of \(t\). Interpretation of function symbols and terms are defined the following way:
- \(\Phi\left(\left\langle T_{1}, T_{2}\right\rangle\right)\) is the tree with root node labelled Pair and its two ordered children are roots of the trees \(\Phi\left(T_{1}\right)\) and \(\Phi\left(T_{2}\right)\).
- \(\Phi\left(\{T\}_{Q}^{s}\right)\) is defined similarly: It is the tree with the root node labelled as PKEnc, and its first chiled is labelled by \(\Phi(Q)\), the second is the root of \(\Phi(T)\), the third is labeled by \(\Phi(s) . \Phi\left(\{T\}_{Q Q^{\prime}}^{s}\right)\) and \(\Phi\left(\{T\}_{k}^{s}\right)\) are defined similarly.
- \(\Phi(\bar{T})\) is a sequence of random variables because \(\bar{T}\) is of sort bitstring. It is computed the following way: Its value \(\Phi(\bar{T})^{\eta}(\omega)\) is given by taking the values given by the labels on the leafs at \(\eta\) and \(\omega\), and carrying out the encryptions and pairings indicated by the labels on the tree. For example,
\[
\begin{aligned}
& \Phi\left(\overline{\left\{\langle N, K\}_{Q}^{s}\right.}\right)^{\eta}(\omega)= \\
& \mathcal{E}_{a}\left(\left[\mathcal{K}_{Q}^{\eta}(\omega), \Phi(N)^{\eta}(\omega), \Phi(K)^{\eta}(\omega)\right], \Phi(s)^{\eta}(\omega)\right)
\end{aligned}
\]

Where \(\mathcal{K}_{Q}\) is the key of \(Q\).
Finally, the interpretation of predicates:
- \(t={ }_{\Delta} t^{\prime}\) means that the tree structure of \(\Phi(t)\) and \(\Phi\left(t^{\prime}\right)\) are identical, with identical internal labels, and the random variables labeling the leafs that are not of sort coin are identical up to negligible probability, and further, if we compute the operations indicated by the tree, the results are also the same except for negligible probability on \(\Phi(\Delta) . \Delta=\Delta^{\prime}\) means \(P\left(\left(\Phi(\Delta)^{\eta} \cup \Phi\left(\Delta^{\prime}\right)^{\eta}\right) \backslash\left(\Phi(\Delta)^{\eta} \cap \Phi\left(\Delta^{\prime}\right)^{\eta}\right)\right)\) is negligible in \(\eta\), that is, \(\Phi(\Delta)^{\eta}\) and \(\Phi(\Delta)^{\eta}\) are the same up to negligible probability. \(\tau=\Delta \tau^{\prime}\) means \(P\left(\omega \mid \omega \in \Phi(\Delta)^{\eta} \wedge \Phi(\tau)^{\eta}(\omega) \neq \Phi\left(\tau^{\prime}\right)^{\eta}(\omega)\right)\) is negligible in \(\eta\).
- \(t \sqsubseteq_{\Delta} t^{\prime}\) means \(\Phi(t)\) equals in the above sense on \(\Phi(\Delta)\) to a subtree of \(\Phi\left(t^{\prime}\right)\), such that it is not a name or seed argument of an encryption.
- \(\tau<\Delta \tau^{\prime}\) means \(P\left(\omega \mid \omega \in \Phi(\Delta)^{\eta} \wedge \Phi(\tau)^{\eta}(\omega) \nless\right.\) \(\left.\Phi\left(\tau^{\prime}\right)^{\eta}(\omega)\right)\) is negligible in \(\eta\).
- \(\Delta \subseteq \Delta^{\prime}\) means \(P\left(\Phi(\Delta)^{\eta} \backslash \Phi\left(\Delta^{\prime}\right)^{\eta}\right)\) is negligible
- \(Q\) generates \(\left.{ }_{\tau}^{i} N\right|_{\Delta}\)

Up to negligible probability, for \(\omega \in \Phi(\Delta)^{\eta}\), \(\xi(\tau(\omega), \omega)\) indicates the generation of a nonce by \(Q\) in its session \(i\) and writing it in a designated register.
- \(Q\) receives \(\left._{\tau}^{i} t\right|_{\Delta}\)

Up to negligible probability, for \(\omega \in \Phi(\Delta)^{\eta}\), \(\xi(\tau(\omega), \omega)\) indicates that \(Q\) received a message which is than parsed the way \(t\) indicates it, each subterm being recorded in some register.
- \(\left.Q \operatorname{sends}{ }_{\tau}^{i} t\right|_{\Delta}\)

Up to negligible probability, for \(\omega \in \Phi(\Delta)^{\eta}\), \(\xi(\tau(\omega), \omega)\) indicates that \(Q\) sent a message which was previously put together the way \(t\) indicates it.
- \(\left.\operatorname{Sec}_{\tau}\left(\left\langle A_{1}, \ldots A_{n}\right\rangle, t, \nu\right)\right|_{\Delta}\)

Satisfaction of this formula means the following: An adversary that is provided with \(\Phi(t)^{\eta}(\omega)\) as well as the joint information available on \(\omega\) until \(\tau(\omega)^{\eta}\) to the principals other \(A_{1}, \ldots A_{n}\) and to the protocol adversary, cannot distinguish \(\nu\) from a nonce (or key respectively) generated independently of the protocol (with the same distribution that \(\nu\) has restricted to \(\Phi(\Delta)^{\eta}\).
- \(\left.\operatorname{KeySec}_{\tau}\left(\left\langle A_{1}, \ldots A_{n}\right\rangle, t, K\right)\right|_{\Delta}\)

This is called key-secrecy predicate. It is satisfied if \(A_{1}, \ldots A_{n}\) can safely encrypt messages using \(K\) until (not including) \(\tau\) in \(\Delta\), even if \(t\) is given to them. By this we mean, that an adversary playing the security game for the encryption, cannot win the game even if provided with \(\Phi(t)^{\eta}(\omega)\) as well as the joint information available on \(\omega\) until \(\tau(\omega)^{\eta}\) to the principals other \(A_{1}, \ldots A_{n}\) and to the protocol adversary.

With these definitions, and if the encryptions and pairings satisfy the above mentioned security properties, the axioms that we listed are sound. A completely rigorous proof using probabilistic random access machines is being prepared for submission to a journal.

\section*{B. Possible variations}

We would like to indicate some possible variations to the syntax that we gave.

\section*{B.1. Sorts}

For example, when the lengths of keys and nonces are fixed, it make sense to have the following sort structure:
\(\left.\begin{array}{r}\text { hseed } \\ \text { hname } \subseteq \text { name } \\ \text { hnonce } \subseteq \text { nonce } \\ \text { hkey } \subseteq \text { key } \\ \text { sessionid }\end{array}\right\} \subseteq\) bitstring \(\subseteq\) bittree

Our analysis would still be valid without modifications, but the meaning of notation would be a little different. We ac-
\begin{tabular}{|c|c|}
\hline hseed & \(r, r^{\prime}, \ldots, r_{1}, r_{2}\) \\
\hline hname & \(A, B, \ldots, A_{1}, A_{2}, \ldots\) \\
\hline name & \(Q, Q^{\prime} \ldots, Q_{1}, Q_{2}, \ldots\) \\
\hline hnonce & \(N, N^{\prime}, \ldots, N_{1}, N_{2}, \ldots\) \\
\hline nonce & \(n, n^{\prime}, \ldots, n_{1}, n_{2}, \ldots\) \\
\hline hkey & \(K, K^{\prime}, \ldots, K_{1}, K_{2}, \ldots\) \\
\hline key & \(k, k^{\prime}, \ldots, k_{1}, k_{2}, \ldots\) \\
\hline nonce or hkey & \(\nu, \nu^{\prime}, \ldots, \nu_{1}, \nu_{2}, \ldots\) \\
\hline sessionid & \(i, i^{\prime}, \ldots, i_{1}, i_{2}, \ldots\) \\
\hline bitstring & \(s, s^{\prime}, \ldots, s_{1}, s_{2}, \ldots\) \\
\hline bittree & \(m, m^{\prime}, \ldots, m_{1}, m_{2}, \ldots\) \\
\hline t, \(, \ldots, t_{1}, t_{2}, \ldots\) \\
\hline timesection & \(\tau, u^{\prime}, \ldots, u_{1}, u_{2}, \ldots, \tau_{1}, \tau_{2}, \ldots\) \\
\hline event & \(\Delta, \Delta^{\prime}, \ldots, \Delta_{1}, \Delta_{2}, \ldots\) \\
\hline any variable & \(v, v^{\prime}, \ldots, v_{1}, v_{2}, \ldots\) \\
\hline
\end{tabular}

Table 2. Notation of variables
tually did assume that lengths of nonces and keys are fixed, but we did not include nonce and key because we wanted axioms that work for stricter security (and variable nonce and key length) too, namely when length is hidden.

\section*{B.2. Reveal}

As we mentioned, axiom VI. 2 is not written to account for the reveal action. To incorporate that, we would need two properties:
\[
\begin{aligned}
& {[\text { Key }] \text { SecSend }\left(\vec{A}, C, C^{\prime}, \text { Reveal }\right)} \\
& \left.\quad \wedge\left(C[\nu] \wedge C^{\prime}[u] \wedge \nu \not \subset u\right)\right|_{\Delta} \\
& \left.\quad \rightarrow\left[\text { Key }^{\prime}\right] \operatorname{Sec}_{\infty}(\vec{A}, u, \nu)\right|_{\Delta} \\
& \quad \vee \exists \Delta^{\prime} \tau \vec{m}\left(\Delta^{\prime} \subseteq \Delta\right. \\
& \left.\left.\quad \wedge\left(\left[\operatorname{Key}^{\prime}\right] \operatorname{Sec}_{\tau}(\vec{A}, u, \nu) \wedge \operatorname{Reveal}_{\tau}(\vec{A}, \nu)\right)\right|_{\Delta^{\prime}}\right)
\end{aligned}
\]
and
\[
\begin{aligned}
& {[\text { Key }] \operatorname{SecSend}\left(\vec{A}, C, C^{\prime}, \text { Reveal }\right)} \\
& \left.\quad \wedge\left(C[\nu] \wedge C^{\prime}[u] \wedge \nu \nsubseteq u \wedge \operatorname{Reveal}_{\tau}(\vec{A}, \nu)\right)\right|_{\Delta} \\
& \left.\quad \rightarrow\left[K_{\text {Key }}\right] \operatorname{Sec}_{\tau}(\vec{A}, u, \nu)\right|_{\Delta}
\end{aligned}
\]

\section*{B.3. Shared-key unforgeability}

As we mentioned, it would also make sense to write the axioms for existential unforgeability. In that case, we have
(4) Authentication with long-term shared key:
\[
\begin{aligned}
& \text { A receives } i_{2}^{i_{2}} t_{2} \wedge\{t\}_{A B}^{s} \sqsubseteq t_{2} \\
& \quad \rightarrow \exists A^{\prime} i_{1} t_{1} t^{\prime}\left(\left(A^{\prime}=A \vee A^{\prime}=B\right)\right. \\
& \wedge A^{\prime} \text { sends } s_{\tau_{1}}^{i_{1}} t_{1} ; A \text { receives } \tau_{\tau 2}^{i_{2}} t_{2} \wedge\left\{t^{\prime}\right\}_{A B}^{r} \sqsubseteq t_{1} \\
& \left.\left.\quad \wedge\{t\}_{A B}^{s}=\left\{t^{\prime}\right\}_{A B}^{r}\right)\right)
\end{aligned}
\]
(5) Authentication with shared session key
(a) KeySec \(_{\tau_{2}}(\vec{A}, K) \wedge A\) receives \(_{\tau_{2}}^{i_{2}} t_{2} \wedge\{t\}_{K}^{s} \sqsubseteq t_{2}\)
\[
\begin{aligned}
& \rightarrow \exists A^{\prime} i_{1} t_{1} t^{\prime} r \tau_{1}\left(A^{\prime} \sqsubseteq \vec{A} \wedge A^{\prime} \text { sends }_{\tau_{1}}^{i_{1}} t_{1} ; A \text { receives } \tau_{\tau_{2}}^{i_{2}} t_{2}\right. \\
& \\
& \left.\wedge\left\{t^{\prime}\right\}_{K}^{r} \sqsubseteq t_{1} \wedge \overline{\{t\}_{K}^{s}}=\overline{\left\{t^{\prime}\right\}_{K}^{r}}\right)
\end{aligned}
\]

With these properties, agreement and authentication from the initiator's proof in the sNS protocol can also be proven.```
