## Abstract

Helios 2.0 is an open-source web-based end-to-end verifiable electronic voting system, suitable for use in low-coercion environments. In this article, we analyse ballot secrecy and discover a vulnerability which allows an adversary to compromise the privacy of voters. The vulnerability exploits the absence of ballot independence in Helios and works by replaying a voter's ballot or a variant of it, the replayed ballot influences the election outcome, introducing information that can be used to violate privacy. We demonstrated the practicality of the attack by breaking privacy in a mock election using the current Helios implementation. Moreover, the feasibility of an attack is considered in the context of French legislative elections and, based upon our findings, we believe it constitutes a real threat to ballot secrecy in such settings. We present a fix and show that our solution satisfies a formal definition of ballot secrecy using the applied pi calculus. In addition, we present attacks against other electronic voting schemes which do not assure ballot independence; in particular, we show a similar vulnerability in the protocol by Lee *et al.* and demonstrate replay attacks against the schemes by Sako & Kilian and Schoenmakers. Finally, we argue that no general relationships exist between independence and privacy properties.

**Keywords.** Applied Pi Calculus, Attack, Ballot Independence, Ballot Secrecy, Electronic Voting, Fiat-Shamir Heuristic, Helios, Malleability, Privacy, Replay.

\*A preliminary version of this article was presented at CSF'11 [26]. Ben Smyth's work was partly done at Loria, CNRS & INRIA Nancy Grand Est, France.

# 1 Introduction

Paper-based elections derive security properties from physical characteristics of the real-world. For example, marking a ballot in the isolation of a polling booth and depositing the completed ballot into a locked ballot box provides privacy; the polling booth also ensures that voters cannot be influenced by other votes and the locked ballot box prevents the announcement of early results, thereby ensuring fairness; and the transparency of the whole election process from ballot casting to tallying and the impossibility of altering the markings on a paper ballot sealed inside a locked ballot box gives an assurance of correctness and facilitates verifiability. Replicating these attributes in a digital setting has proven to be difficult and, hence, the provision of secure electronic voting systems is an active research topic.

Informally, *privacy* for electronic voting systems is characterised by the following requirements [49, 30, 9]:

- *Ballot secrecy.* A voter's vote is not revealed to anyone.
- *Receipt freeness.* A voter cannot gain information which can be used to prove, to a coercer, how she voted.
- *Coercion resistance.* A voter cannot collaborate, with a coercer, to gain information which can be used to prove how she voted.

*Verifiability* includes three properties [47, 62, 50]:

- *Individual verifiability.* A voter can check that her own ballot is published on the election's bulletin board.
- *Universal verifiability.* Anyone can check that all the votes in the election outcome correspond to ballots published on the election's bulletin board.
- *Eligibility verifiability.* Anyone can check that each ballot published on the bulletin board was cast by a registered voter and at most one ballot is tallied per voter.

Finally, *fairness* – summarised by the notion that *all voters are equal* – has not been thoroughly studied, but nonetheless we believe the following aspects are desirable:

- *Ballot independence.* Observing another voter's interaction with the election system does not allow a voter to cast a *related* vote.
- *No early results.* A voter cannot change her vote once partial results are available.
- *Pulling out.* Once partial results are available a voter cannot abort.

The fairness property prohibits the voting system from influencing a voter's vote; more formally, this requires that observation of the voting system (that is,

observing interaction between participants) does not leak information that may affect a voter’s decision. The individual, universal and eligibility verifiability properties (also called *end-to-end verifiability* [46, 20, 4, 62, 5]) allow voters and election observers to verify – independently of the hardware and software running the election – that votes have been recorded, tallied and declared correctly. In this article, we analyse ballot secrecy in Helios 2.0 [7].

**The Helios protocol.** Helios is an open-source web-based electronic voting system. The scheme is claimed to satisfy ballot secrecy [7], but the nature of remote voting makes the possibility of satisfying stronger privacy properties difficult, and Helios does not satisfy receipt freeness nor coercion resistance. In addition to ballot secrecy, the system provides individual and universal verifiability (cf. [50, 78] and [75, Chapter 3] for an analysis of verifiability in Helios). Helios is particularly significant due to its real-world deployment: the International Association of Cryptologic Research used Helios to elect its board members [13], following a successful trial in a non-binding poll [45]; the Catholic University of Louvain adopted the system to elect the university president [7]; and Princeton University used Helios to elect the student vice president [66].

Formal definitions of ballot secrecy have been introduced in the context of the applied pi calculus by Delaune, Kremer & Ryan [49, 30, 31, 32] and Backes, Hrițcu & Maffei [9]. These privacy definitions consider two voters  $\mathcal{A}$ ,  $\mathcal{B}$  and two candidates  $t$ ,  $t'$ . Ballot secrecy is captured by the assertion that an adversary (controlling arbitrary many dishonest voters) cannot distinguish between a situation in which voter  $\mathcal{A}$  votes for candidate  $t$  and voter  $\mathcal{B}$  votes for candidate  $t'$ , from another situation in which  $\mathcal{A}$  votes  $t'$  and  $\mathcal{B}$  votes  $t$ . This can be expressed by the following equivalence.

$$\mathcal{A}(t) \mid \mathcal{B}(t') \approx_l \mathcal{A}(t') \mid \mathcal{B}(t)$$

These formal definitions of ballot secrecy have been used by their respective authors to analyse the electronic voting protocols due to: Fujioka, Okamoto & Ohta [42], Okamoto [59], Lee *et al.* [55], and Juels, Catalano & Jakobsson [46, 47, 48]. It therefore seems natural to check whether Helios satisfies ballot secrecy as well.

**Contribution.** Our analysis of Helios reveals an attack which violates ballot secrecy. The attack exploits the system’s lack of ballot independence, and works by replaying a voter’s ballot or a variant of it (without knowing the vote contained within that ballot). Replayng a voter’s ballot immediately violates ballot secrecy in an election with three voters. For example, consider the electorate Alice, Bob, and Mallory; if Mallory replays Alice’s ballot, then Mallory can reveal Alice’s vote by observing the election outcome and checking which candidate obtained at least two votes. The practicality of this attack has been demonstrated by violating privacy in a mock election using the current Helios implementation. Furthermore, the vulnerability can be exploited in more realistic settings and,

as an illustrative example, we discuss the feasibility of the attack in French legislative elections. This case study suggests there is a plausible threat to ballot secrecy. We also propose a variant of the attack which abuses the malleability of ballots to ensure replayed ballots are distinct: this makes identification of replayed ballots non-trivial (that is, checking for exact duplicates is insufficient). Nonetheless, we fix the Helios protocol by identifying and discarding replayed ballots. We believe this solution is particular well-suited because it maintains Benaloh’s principle of ballot casting assurance [11, 12] and requires a minimal extension to the Helios code-base. The revised scheme is shown to satisfy a formal definition of ballot secrecy using the applied pi calculus.

In addition, we demonstrate that the absence of ballot independence can be exploited in other electronic voting protocols to violate privacy; in particular, a similar attack is shown against the protocol by Lee *et al.* [55] whereby an adversary replays a voter’s ballot or a variant of it, and verbatim replay attacks are demonstrated against two schemes presented at CRYPTO (namely, the protocols due to Sako & Kilian [70] and Schoenmakers [72]). Finally, we present some evidence to support the hypothesis that independence does not imply privacy and vice-versa.

**Related work.** The attack against Helios that we discover relies upon the lack of ballot independence (in particular, ballots can be replayed). The concept of independence was introduced by Chor *et al.* [21] and the possibility of compromising security properties due to lack of independence has been considered, for example, by [22, 34, 35, 44]. In the context of electronic voting, Gennaro [43] demonstrates that the application of the Fiat-Shamir heuristic in the Sako-Kilian electronic voting protocol [70] violates ballot independence, and Wikström [83, 84] studies non-malleability for mixnets to achieve ballot independence. By comparison, we focus on the violation of ballot secrecy rather than fairness, and exploit the absence of ballot independence to compromise privacy. Similar results have been shown against mixnets [65].

Our attack is also reliant on the voter’s ability to cast a ballot as a function of another voter’s ballot. In particular, the basic form of our attack applies the identity function, and the variant exploiting malleability performs a permutation on the ballot’s internal structure. In related work, Benaloh [10] demonstrates that a simplified version of his voting scheme allows the administrator’s private key to be recovered by a voter who constructs their ballot as a function of other voters’ ballots.

Estehghari & Desmedt [39] claim to present an attack which undermines privacy and end-to-end verifiability in Helios. However, their attack is dependent on compromising a voter’s computer, a vulnerability which is explicitly acknowledged by the Helios specification [7]: “*a specifically targeted virus could surreptitiously change a user’s vote and mask all of the verifications performed via the same computer to cover its tracks.*” Accordingly, [39] represents an exploration of known vulnerabilities rather than an attack.

Other studies of Helios have also been conducted. In particular, Langer *et*

*al.* [52, 53] and Volkamer & Grimm [80] study privacy in Helios. Langer *et al.* propose a taxonomy of informal privacy requirements [52, 53, 54] to facilitate a more fine-grained comparison of electronic voting systems; this framework is used to analyse Helios and the authors claim ballot secrecy is satisfied if the adversary only has access to public data [52, 53]. Volkamer & Grimm introduce the *k-resilience* metric [80, 79] to calculate the number of honest participants required for ballot secrecy in particular scenarios; this framework is used to analyse Helios and the authors claim ballot secrecy is satisfied if the software developers are honest and the key holders do not collude [80]. Contrary to these results, we show an attack against privacy. Our work highlights the necessity for rigorous mathematical analysis techniques for security protocols; in particular, we believe the erroneous results reported by Langer *et al.* were due to the use of informal methods, and the approach by Volkamer & Grimm failed because only some particular scenarios were considered.

Delaune, Kremer & Ryan [30, 31] have shown that a variant of the Lee *et al.* protocol satisfies coercion resistance for two honest voters; but, based upon our preliminary results [26], Dreier, Lafourcade & Lakhnech [36] demonstrate an attack against privacy for three voters, when one voter is under the adversary’s control<sup>1</sup>. Furthermore, using a stronger definition of coercion resistance, Küsters & Truderung [51] have demonstrated a forced abstention attack; in addition, Küsters & Truderung propose a variant of the scheme by Lee *et al.* which is claimed to satisfy their stronger definition. In this article, we show a new attack against the original Lee *et al.* protocol and show that the revised scheme by Küsters & Truderung might not be secure under reasonable assumptions.

A preliminary version of this work [26] appeared at the 24th Computer Security Foundations Symposium. By comparison, in this article, we provide a more detailed description of our results, generalise our proof of ballot secrecy to a setting with arbitrary many candidates, and include complete proofs. In addition, we show that other electronic voting protocols are vulnerable to our attack and we discuss the link between ballot independence and privacy.

**Structure of this article.** Section 2 presents the Helios electronic voting scheme. (We remark that this is the first cryptographic description of the Helios protocol in the literature and, hence, is an additional contribution of this article.) Section 3 describes our attack and some variants, in addition to a study of its feasibility in the context of French legislative elections. We propose several solutions for recovering privacy in Section 4 and prove that our adopted solution formally satisfies ballot secrecy in Section 5. Section 6 demonstrates that the absence of ballot independence can be similarly exploited in other electronic voting protocols to violate privacy. Finally, our conclusion appears in Section 7.

---

<sup>1</sup>The formal model by Dreier, Lafourcade & Lakhnech includes the voter’s signature on the signed re-encrypted ciphertext and this is exploited by their attack; by comparison, the model by Delaune, Kremer & Ryan omits this detail and therefore the attack cannot be witnessed.

## 2 Background: Helios 2.0

We provide a full description of Helios 2.0. This scheme exploits the additive homomorphic [27, 29, 73] and distributed decryption [63, 19] properties of ElGamal [37]. We will recall these cryptographic details before presenting the Helios protocol.

### 2.1 Additive homomorphic ElGamal

Given cryptographic parameters  $(p, q, g)$  and a number  $n \in \mathbb{N}$  of trustees, where  $p$  and  $q$  are large primes such that  $q \mid p - 1$  and  $g$  is a generator of the multiplicative group  $\mathbb{Z}_p^*$  of order  $q$ , the following operations are defined by ElGamal.

**Distributed key generation.** Each trustee  $i \in n$  selects a private key share  $x_i \in_R \mathbb{Z}_q^*$  and computes a public key share  $h_i = g^{x_i} \bmod p$ . The public key is  $h = h_1 \cdot \dots \cdot h_n \bmod p$ .

**Encryption.** Given a message  $m$  and a public key  $h$ , select a random nonce  $r \in_R \mathbb{Z}_q^*$  and derive the ciphertext  $(a, b) = (g^r \bmod p, g^m \cdot h^r \bmod p)$ .

**Re-encryption.** Given a ciphertext  $(a, b)$  and public key  $h$ , select a random nonce  $r' \in_R \mathbb{Z}_q^*$  and derive the re-encrypted ciphertext  $(a', b') = (a \cdot g^{r'} \bmod p, b \cdot h^{r'} \bmod p)$ .

**Homomorphic addition.** Given two ciphertexts  $(a, b)$  and  $(a', b')$ , the homomorphic addition of plaintexts is computed by multiplication  $(a \cdot a' \bmod p, b \cdot b' \bmod p)$ .

**Distributed decryption.** Given a ciphertext  $(a, b)$ , each trustee  $i \in n$  computes the partial decryption  $k_i = a^{x_i}$ . The plaintext  $m = \log_g M$  is recovered from  $M = b / (k_1 \cdot \dots \cdot k_n) \bmod p$ .

The computation of a discrete logarithm  $\log_g M$  is hard in general. However, if  $M$  is chosen from a restricted domain, then the complexity is reduced; for example, if  $M$  is an integer such that  $0 \leq M \leq n$ , then the complexity is  $O(n)$  by linear search or  $O(\sqrt{n})$  using the baby-step giant-step algorithm [74] (see also [56, §3.1]).

For secrecy, each trustee  $i \in n$  must demonstrate knowledge of a discrete logarithm  $\log_g h_i$ , that is, they prove that  $h_i$  has been correctly constructed; this prevents, for example, a trustee constructing their public key share  $h_i = h$ . For integrity of decryption, each trustee  $i \in n$  must demonstrate equality between discrete logarithms  $\log_g h_i$  and  $\log_a k_i$ ; this prevents, for example, a trustee constructing the public key share  $h_i = g^{m+x_i}$  and providing the partial decryption  $k_i = a^{x_i}$ . In addition, the voter must demonstrate that a valid vote

has been encrypted. These proofs can be achieved using signatures of knowledge (see Appendix A for details).

## 2.2 Protocol description

An election is created by naming an election officer, selecting a set of trustees, and generating a distributed public key pair. The election officer publishes, on the bulletin board, the public part of the trustees' key (and proof of correct construction), the candidate list  $\tilde{t} = (t_1, \dots, t_\ell) \cup \{\epsilon\}$  (where  $\epsilon$  represents a vote of abstention), and the list of eligible voters  $\tilde{id} = (id_1, \dots, id_n)$ ; the officer also publishes the *election fingerprint*, that is, the hash of these parameters. Informally, the steps that participants take during a run of Helios are as follows.

1. The voter launches a browser script that downloads the election parameters and recomputes the election fingerprint. The voter should verify that the fingerprint corresponds to the value published on the bulletin board. (This ensures that the script is using the trustees' public key; in particular, it helps prevent encrypting a vote with an adversary's public key. Such attacks have been discussed in the context of Direct Anonymous Attestation by Rudolph [67]; although, the vulnerability was discounted, in the trusted computing setting, by Leung, Chen & Mitchell [57].)
2. The voter inputs her vote  $v \in \tilde{t}$  to the browser script, which creates a ballot consisting of her vote encrypted by the trustees' public key, and a proof that the ballot represents a permitted vote (this is needed because the ballots are never decrypted individually, in particular, it prevents multiple votes being encoded as a single ballot). The ballot is displayed to the voter.
3. The voter can audit the ballot to check if it really represents a vote for her chosen candidate; if she decides to do this, then the script provides her with the random data used in the ballot creation. She can then independently reconstruct her ballot and verify that it is indeed well-formed. The script provides some practical resistance against vote selling by refusing to cast audited ballots. See Benaloh [11, 12] for further details on ballot auditing.
4. When the voter has decided to cast her ballot, the script submits it to the election officer. The election officer authenticates the voter and checks that she is eligible to vote. The election officer also verifies the proof and publishes the ballot, appended with the voter's identity  $id$ , on the bulletin board. (In practice, the election officer also publishes the hash of the ballot, we omit this detail for brevity.)
5. Individual voters can check that their ballots appear on the bulletin board and, by verifying the proof, observers are assured that ballots represent permitted votes.
6. After some predefined deadline, the election officer homomorphically combines the ballots and publishes the encrypted tally on the bulletin board. Anyone can check that tallying is performed correctly.

---

**Figure 1** Ballot construction by the browser script

---

Input: Cryptographic parameters  $(p, q, g)$ , public key  $h$ , candidate list  $\tilde{t} = (t_1, \dots, t_\ell) \cup \{\epsilon\}$  and vote  $v$ .

Output: Encrypted vote  $(a_1, b_1), \dots, (a_\ell, b_\ell)$ , signatures of knowledge  $(\bar{a}_1, \bar{b}_1, \bar{c}_1, \bar{s}_1, \bar{a}'_1, \bar{b}'_1, \bar{c}'_1, \bar{s}'_1), \dots, (\bar{a}_\ell, \bar{b}_\ell, \bar{c}_\ell, \bar{s}_\ell, \bar{a}'_\ell, \bar{b}'_\ell, \bar{c}'_\ell, \bar{s}'_\ell)$  and signature of knowledge  $(\bar{a}, \bar{b}, \bar{c}, \bar{s}, \bar{a}', \bar{b}', \bar{c}', \bar{s}')$ .

1. If  $v \notin \tilde{t}$  then the script terminates.
2. Encode the vote  $v$  as a bitstring. For all  $1 \leq i \leq \ell$ , let

$$m_i = \begin{cases} 1 & \text{if } v = t_i \\ 0 & \text{otherwise} \end{cases}$$

3. The bitstring representing the vote is encrypted. For all  $1 \leq i \leq \ell$ , let

$$(a_i, b_i) = (g^{r_i} \bmod p, g^{m_i} \cdot h^{r_i} \bmod p)$$

where  $r_i \in_R \mathbb{Z}_q^*$ .

4. For all  $1 \leq i \leq \ell$ , let  $(\bar{a}_i, \bar{b}_i, \bar{c}_i, \bar{s}_i, \bar{a}'_i, \bar{b}'_i, \bar{c}'_i, \bar{s}'_i)$  be a signature of knowledge demonstrating that the ciphertext  $(a_i, b_i)$  contains either 0 or 1, that is, each candidate can receive at most one vote.
  5. Let  $(\bar{a}, \bar{b}, \bar{c}, \bar{s}, \bar{a}', \bar{b}', \bar{c}', \bar{s}')$  be a signature of knowledge demonstrating that the ciphertext  $(a_1 \cdot \dots \cdot a_\ell, b_1 \cdot \dots \cdot b_\ell)$  contains either 0 or 1, that is, at most one candidate receives one vote.
- 

7. Each of the trustees publishes a partial decryption of the encrypted tally, together with a signature of knowledge proving the partial decryption's correct construction. Anyone can verify these proofs.

8. The election officer decrypts the tally and publishes the result. Anyone can check this decryption.

Formally, Step 2 is defined in Figure 1. (For simplicity the ballot construction algorithm in Figure 1 considers a vote  $v \in \tilde{t}$ , this can be generalised [7] to consider a vote  $\tilde{v} \subseteq \tilde{t}$ .) Checking voter eligibility (Step 4) is beyond the scope of Helios and Adida *et al.* [7] propose the use of existing infrastructure. The remaining steps follow immediately from the application of cryptographic primitives (see Section 2.1 for details).

### 2.3 Software implementation

Helios 3.0 is an extension of Helios 2.0 which adds numerous practical features, including: integration of authentication with various web-services (for example,

Facebook, GMail and Twitter), bulk voter registration using pre-existing electoral rolls, and simplification of administration with multiple trustees. Helios 3.0 has been implemented and is publicly available: <http://heliosvoting.org/>.

### 3 Attacking ballot secrecy

Ballot secrecy means a voter’s vote is not revealed to anyone. We show that the Helios protocol does not satisfy this definition of ballot secrecy, by presenting an attack which allows an adversary to reveal a voter’s vote. Moreover, we will show that formal definitions of ballot secrecy [49, 31, 9] are also violated.

Intuitively, an adversary may identify a voter’s ballot on the bulletin board (using the voter’s *id*) and recast this ballot by corrupting dishonest voters. The multiple occurrences of the voter’s ballot will leak information in the tally and the adversary can exploit this knowledge to violate the voter’s privacy. An informal description of the attack will now be presented in the case of three eligible voters and Section 3.3 considers a more realistic setting. (A formal analysis appears in Section 4.)

#### 3.1 Attack description

Let us consider an election with candidates  $t_1, \dots, t_\ell$  and three eligible voters who have identities  $id_1, id_2$  and  $id_3$ . Suppose that voters  $id_1$  and  $id_2$  are honest, and  $id_3$  is a dishonest voter controlled by the adversary. Further assume that the honest voters have cast their ballots. The bulletin board entries are as follows:

$$\begin{aligned} & id_1, ciph_1, spk_1, spk'_1 \\ & id_2, ciph_2, spk_2, spk'_2 \end{aligned}$$

where for  $i \in \{1, 2\}$  we have

$$\begin{aligned} ciph_i &= (a_{i,1}, b_{i,1}), \dots, (a_{i,\ell}, b_{i,\ell}) \\ spk_i &= (\bar{a}_{i,1}, \bar{b}_{i,1}, \bar{c}_{i,1}, \bar{s}_{i,1}, \bar{a}'_{i,1}, \bar{b}'_{i,1}, \bar{c}'_{i,1}, \bar{s}'_{i,1}), \\ & \dots, (\bar{a}_{i,\ell}, \bar{b}_{i,\ell}, \bar{c}_{i,\ell}, \bar{s}_{i,\ell}, \bar{a}'_{i,\ell}, \bar{b}'_{i,\ell}, \bar{c}'_{i,\ell}, \bar{s}'_{i,\ell}) \\ spk'_i &= (\bar{a}_i, \bar{b}_i, \bar{c}_i, \bar{s}_i, \bar{a}'_i, \bar{b}'_i, \bar{c}'_i, \bar{s}'_i) \end{aligned}$$

The value  $ciph_i$  is the  $i$ th voter’s encrypted vote,  $spk_i$  demonstrates that ciphertexts  $(a_{i,1}, b_{i,1}), \dots, (a_{i,\ell}, b_{i,\ell})$  contain either 0 or 1, and  $spk'_i$  demonstrates that  $(a_{i,1} \cdot \dots \cdot a_{i,\ell}, b_{i,1} \cdot \dots \cdot b_{i,\ell})$  contains either 0 or 1.

**Exploiting the absence of ballot independence.** The adversary observes the bulletin board and selects  $ciph_k, spk_k, spk'_k$  such that  $id_k$  is the voter whose privacy will be compromised, where  $k \in \{1, 2\}$ . The adversary submits the ballot  $ciph_k, spk_k, spk'_k$  and it immediately follows that the bulletin board is composed as follows:

$$\begin{aligned}
& id_1, ciph_1, spk_1, spk'_1 \\
& id_2, ciph_2, spk_2, spk'_2 \\
& id_3, ciph_k, spk_k, spk'_k
\end{aligned}$$

It is trivial to see that each bulletin board entry represents a permitted vote; that is,  $spk_1, spk'_1, spk_2, spk'_2, spk_k, spk'_k$  all contain valid signatures of knowledge.

We have informally shown that Helios does not satisfy ballot independence (observing another voter's interaction with the election system allows a voter to cast the *same* vote), and this will now be exploited to violate privacy.

**Violating privacy.** The homomorphic addition of ballots reveals the encrypted tally  $(a_{1,1} \cdot a_{2,1} \cdot a_{k,1}, b_{1,1} \cdot b_{2,1} \cdot b_{k,1}), \dots, (a_{1,\ell} \cdot a_{2,\ell} \cdot a_{k,\ell}, b_{1,\ell} \cdot b_{2,\ell} \cdot b_{k,\ell})$  and, given the partial decryptions, these ciphertexts can be decrypted to reveal the number of votes for each candidate. Since there will be at least two votes for the candidate voter  $id_k$  voted for, the voter's vote can be revealed and hence privacy is not preserved. Moreover, the vote of the remaining honest voter will also be revealed.

A video demonstrating the attack against the Helios 3.0 implementation has been produced [76].

### 3.2 Variants exploiting malleability and key reuse

In the aforementioned attack description, the ballots cast by two voters are identical which may result in the detection of an attack. For a covert attack, the adversary may prefer to cast a distinct ballot. This can be achieved by exploiting the malleability of ballots. In particular, given a valid ballot

$$\begin{aligned}
& (a_1, b_1), \dots, (a_\ell, b_\ell), (\bar{a}_1, \bar{b}_1, \bar{c}_1, \bar{s}_1, \bar{a}'_1, \bar{b}'_1, \bar{c}'_1, \bar{s}'_1), \dots, \\
& (\bar{a}_\ell, \bar{b}_\ell, \bar{c}_\ell, \bar{s}_\ell, \bar{a}'_\ell, \bar{b}'_\ell, \bar{c}'_\ell, \bar{s}'_\ell), (\bar{a}, \bar{b}, \bar{c}, \bar{s}, \bar{a}', \bar{b}', \bar{c}', \bar{s}') \quad (\text{B1})
\end{aligned}$$

the following ballots are also valid

$$\begin{aligned}
& (a_1, b_1), \dots, (a_\ell, b_\ell), (\bar{a}_1, \bar{b}_1, \bar{c}_1, \bar{s}_1 + q, \bar{a}'_1, \bar{b}'_1, \bar{c}'_1, \bar{s}'_1 + q), \dots, \\
& (\bar{a}_\ell, \bar{b}_\ell, \bar{c}_\ell, \bar{s}_\ell + q, \bar{a}'_\ell, \bar{b}'_\ell, \bar{c}'_\ell, \bar{s}'_\ell + q), (\bar{a}, \bar{b}, \bar{c}, \bar{s} + q, \bar{a}', \bar{b}', \bar{c}', \bar{s}' + q) \quad (\text{B2})
\end{aligned}$$

$$\begin{aligned}
& (a_{\pi(1)}, b_{\pi(1)}), \dots, (a_{\pi(\ell)}, b_{\pi(\ell)}), \\
& (\bar{a}_{\pi(1)}, \bar{b}_{\pi(1)}, \bar{c}_{\pi(1)}, \bar{s}_{\pi(1)}, \bar{a}'_{\pi(1)}, \bar{b}'_{\pi(1)}, \bar{c}'_{\pi(1)}, \bar{s}'_{\pi(1)}), \dots, \\
& (\bar{a}_{\pi(\ell)}, \bar{b}_{\pi(\ell)}, \bar{c}_{\pi(\ell)}, \bar{s}_{\pi(\ell)}, \bar{a}'_{\pi(\ell)}, \bar{b}'_{\pi(\ell)}, \bar{c}'_{\pi(\ell)}, \bar{s}'_{\pi(\ell)}), \\
& (\bar{a}, \bar{b}, \bar{c}, \bar{s}, \bar{a}', \bar{b}', \bar{c}', \bar{s}') \quad (\text{B3})
\end{aligned}$$

where  $\pi$  is an arbitrary permutation over  $\{1, \dots, \ell\}$ . Ballot B2 adds  $q$  to the response components of Ballot B1, this changes the ballot but not the vote. (It

is also possible to modify a subset of the response components.) However, this might be considered an implementation bug in Helios 3.0, rather than a theoretical issue, because the ballots are identical if considered as group elements. Replaying Ballot B3 has the advantage of casting a theoretical distinct ballot, since Ballot B3 represents a vote for a different candidate (with the exception of an abstention vote), and it is possible to compromise ballot secrecy in elections with three voters without abstention votes; however, more than one (modified) ballot may be required in elections with abstention votes. This variant of our attack also demonstrates a further violation of ballot independence in Helios: observing another voter’s interaction with the election system allows a voter to cast a *different* vote (for example, a voter can cast a distinct vote from their boss). Both variants of the attack are particularly useful when the bulletin board includes the hash of the ballot (for example, in the Helios 3.0 implementation), rather than the complete ballot, because the hashes will be distinct.

An adversary may replay ballots in different elections, when the trustees’ public key is reused and the candidate lists for each election are of equal length. This variant of the attack can be avoided if distinct keys are used for each election.

The variants of our attack in this section have all been successfully launched against the Helios 3.0 implementation.

### 3.3 Generalised attack and French election case study

Our attack demonstrates that the ballot of an arbitrary voter can be replayed by any other voter. In general, this does not reveal the voter’s vote; but, some information is leaked, and colluding voters can replay sufficiently many ballots to leak the voter’s vote. We will now discuss the feasibility of compromising ballot secrecy in a real-world election, focusing on the cost of an attack in French legislative elections, where each district elects a representative for the French National Assembly. Districts have several polling stations and each polling station individually announces its tally [40]; these tallies are published in local newspapers. The publication of tallies is typical of French elections at all levels; for example, from the election of mayor, to the presidential election.

In this (standard) voting configuration, an adversary can violate the ballot secrecy of a given voter by corrupting voters registered at the same polling station (for example, a coalition of neighbours or a family). The corrupted voters replay the ballot of the voter under attack, as previously explained. The motivation for restricting the selection of corrupted voters to the same polling station is twofold. Firstly, fewer corrupt voters are required to significantly influence the tally of an individual polling station (in comparison to influencing the election outcome). Secondly, it is unlikely to change the district’s elected representative, because a candidate will receive only a few additional votes in the district; it follows that coercing voters to sacrifice their vote, for the purposes of the attack, should be easier. In the remainder of this section, we discuss how many corrupt voters are required to violate ballot secrecy – by making a significant change in the tally of a polling station – in an arbitrary district of

Party	Tally

Émergence	113
Liste chrétienne	113

Table 1: 2010 legislative election results in Aulnay-sous-Bois [41]

Aulnay-sous-Bois and a rural district in Toul.

### 3.3.1 Ballot secrecy in Aulnay-sous-Bois

Using historic data and/or polls, it is possible to construct the expected distribution of votes. For simplicity, let us assume the distribution of votes per polling station is the average of the 2010 tally (Table 1), and that if the adversary can increase the number of votes for a particular candidate by more than  $\sigma$  (by replaying a voter’s ballot), then this is sufficient to determine that the voter voted for that candidate. In addition, suppose that the adversary corrupts abstaining voters and therefore we do not consider the redistribution of votes. We remark that corrupting abstaining voters may be a fruitful strategy, since abstaining voters do not sacrifice their vote by participating in an attack.

Table 2 presents the expected distribution of votes, and includes the number of voters that an adversary must corrupt to determine if a voter voted for a particular candidate, for various values of  $\sigma$ . We shall further assume that participation in the region is consistent with 2010; that is, 291 of the 832 eligible voters are expected to participate. It follows that 50 voters corresponds to approximately 6% of the Aulnay-sous-Bois electorate, and 10 voters corresponds to approximately 1%. Our results therefore demonstrate that the privacy of a voter can be compromised by corrupting a small number of voters. In particular, for medium-size parties (in terms of votes received) – including, for example, FN and Europe Ecologie – it is sufficient to corrupt 19 voters to see the number of votes increase by 50%. Furthermore, given the low turn-out (541 voters are expected to abstain), it seems feasible to corrupt abstaining voters, and therefore an attack can be launched without any voter sacrificing their vote.

Party	Expected tally	$\sigma = 200\%$	$\sigma = 150\%$	$\sigma = 50\%$	$\sigma = 20\%$
PS	81	162	122	41	17
UMP	68	136	102	34	14
FN	38	76	57	19	8
Europe Eco.	38	76	57	19	8
Front de gauche	17	34	26	9	4
NPA	14	28	21	7	3
MODEM	9	18	14	5	2

LO	3	6	5	2	1
Émergence	2	4	3	1	1
Liste chrétienne	2	4	3	1	1

Table 2: Number of duplicate ballots for a significant change in the tally

**Limitations.** For such an attack based on a statistical model, we acknowledge that this model is rather naïve, but believe it is sufficiently indicative to illustrate the real threat of an attack against privacy. A definitive mathematical analysis should be considered in the future.

**Cases of complete privacy breach.** The probabilistic nature of these attacks may introduce sufficient uncertainty to prevent privacy violations, and we will consider voting configurations where an adversary can definitively learn a voter’s vote. Observe that if an attacker can corrupt half of the voters at a polling station, then the vote of an arbitrary voter can be revealed. Moreover, the cost of this attack can be reduced. In particular, if  $n$  dishonest voter’s replay voter  $\mathcal{V}$ ’s ballot, then it is possible to deduce that  $\mathcal{V}$  did not vote for any candidate that received strictly less than  $n + 1$  votes. This leaks information about voter  $\mathcal{V}$ ’s chosen candidate and in cases where exactly one candidate received more than  $n$  votes, the voter’s vote can be deduced.

### 3.3.2 Ballot secrecy in small polling stations

The difficulties of large scale corruption may prohibit our attack in the majority of polling stations; however, our attack is feasible in small polling stations found in rural districts. For example, let us consider the 2007 legislative elections in the district of Toul [38]. This district has 75350 eligible voters registered at 193 polling stations. Accordingly, the average polling station has 390 registered voters, but the variance is large. Indeed, 33 polling stations have between 50 and 99 voters, 9 polling stations have less than 50 voters, and the smallest two polling stations have 8, respectively 16, voters. Moreover, the attack is simplified by non-participating voters. In these small polling stations it is thus sufficient to corrupt a very small number of voters to reveal a voter’s vote while the final outcome of the election would not change as it is based on 75350 eligible voters.

## 4 Solution: Weeding replayed ballots

Our attack exploits the possibility of replaying a voter’s ballot without detection, and can be attributed to the lack of ballot independence in Helios. This section sketches some possible solutions to ensure ballot independence.

### 4.1 Weeding replayed ballots

The ballots replayed in our attacks can all be identified. First, ciphertexts and signatures of knowledge should have a unique representation as group elements, for example, by requiring that the response component of signatures of knowledge is in the interval  $[0, q - 1]$ . Second, a ballot should not contain a ciphertext that already exists on the bulletin board. The election officer should reject ballots that do not satisfy these conditions. This solution is simple and can easily be implemented in a future version of Helios.

## 4.2 Binding ballots to voters

The previous approach requires a special mechanism to handle replayed ballots. We now propose a technique that makes such actions futile. In essence, based upon inspiration from [43, §4.2] and [29], we ensure that proofs associated with replayed ballots are considered invalid; that is, we bind the link between a voter and her ballot. This is achieved by adding the identity of the voter in the construction of challenges used by signatures of knowledge. More precisely, for voter  $id$ , the sign algorithm (defined in Appendix A) is modified as follows: on input  $(a, b)$ , such that  $a \equiv g^r \pmod{p}$  and  $b \equiv h^r \cdot g^m \pmod{p}$ , let challenge  $c_m = \mathcal{H}(a_{\min}, b_{\min}, \dots, a_{\max}, b_{\max}, id) - \sum_{i \in \{\min, \dots, m-1, m+1, \dots, \max\}} c_i \pmod{q}$ , where values  $a_{\min}, b_{\min}, \dots, a_{\max}, b_{\max}$  and  $c_1, \dots, c_{m-1}, c_{m+1}, \dots, c_m$  are defined as before. For correctness, the verification algorithm must also be modified. In particular, for candidate signatures constructed by voter  $id$ , the verifier should check  $\mathcal{H}(a_{\min}, b_{\min}, \dots, a_{\max}, b_{\max}, id) \equiv \sum_{\min \leq i \leq \max} c_i \pmod{q}$ .

In a similar direction, the electronic voting protocol proposed by Juels, Catalano & Jakobsson [47] – which has been implemented by Clarkson, Chong & Myers [24, 23] as Civitas – requires ballots to be bound to private voter credentials. This provides *eligibility verifiability* [50]: anyone can check that each ballot published on the bulletin board was cast by a registered voter and at most one ballot is tallied per voter. It is likely that eligibility verifiability enforces ballot independence, but the provision of eligibility verifiability appears to be expensive, in particular, Juels, Catalano & Jakobsson and Clarkson, Chong & Myers assume the existence of an infrastructure for voter credentials.

## 4.3 Discussion

Our *weeding replayed ballots* solution is particularly attractive because it adheres to Benaloh’s notion of *ballot casting assurance* [11, 12] which asserts that the ballot encryption device (the browser script in this instance) does not know the voter’s identity. (We remark that neither the original Helios scheme nor our proposed fix strictly satisfy Benaloh’s notion of ballot casting assurance if a voter decides to use her own computer.) The ballot casting assurance principle is important because knowledge of the voter’s identity could be used to infer the likelihood of auditing and this information can be used to influence the behaviour of the ballot encryption device; in particular, if a ballot is unlikely to be audited, then the device may act maliciously, for example, by encrypting a different vote. By comparison, the *binding ballots to voters* solution would necessarily require that the voter’s identity is revealed to the ballot encryption device. Moreover, for privacy purposes, the election officer may choose to allocate voters with pseudo-identities when casting ballots (rather than associate ballots with actual voter identities); since these pseudo-identities are unknown to voters in advance, an additional interaction with the election officer would be required. (Note that the use of pseudo-identities does not prevent the attack by breaking the link between ballots and voters, because the link is known by the election officer.) Finally, extending Helios to provide eligibility verifiability

would require a considerable extension to the Helios code-base and, furthermore, finding a suitable solution is an open problem. Accordingly, we adopt the weeding replayed ballot solution and, in the next section, we show that this is sufficient to ensure ballot secrecy, in the formal setting.

## 5 Formal proof of ballot secrecy

We formally prove that weeding duplicate ballots ensures ballot secrecy. We make use of the applied pi calculus [1, 68], due to its proven suitability for evaluating security properties of electronic voting protocols (see, for example, [31, 9, 50]).

### 5.1 Applied pi calculus

We first recall the applied pi calculus setting [1]. We assume an infinite set of *names*  $a, b, c, \dots, k, \dots, m, n, \dots, s, \dots$ , an infinite set of *variables*  $x, y, z, \dots$ , and a *signature*  $\Sigma$  consisting of a finite set of *function symbols*, each with an associated arity. We use metavariables  $u, w$  to range over both names and variables. *Terms*  $L, M, N, T, U, V$  are built by applying function symbols to names, variables, and other terms. We write  $\{M/x\}$  for the *substitution* that replaces the variable  $x$  with the term  $M$ . Arbitrarily large substitutions can be written as  $\{M_1/x_1, \dots, M_l/x_l\}$  and the letters  $\sigma$  and  $\tau$  range over substitutions. We write  $N\sigma$  for the result of applying  $\sigma$  to the free variables of term  $N$ . A term is *ground* when it does not contain variables.

The signature  $\Sigma$  is equipped with an *equational theory*  $E$ , that is, a set of equations of the form  $M = N$ , where the terms  $M, N$  are defined over the signature  $\Sigma$ . We define equality modulo the equational theory, written  $=_E$ , as the smallest equivalence relation on terms that contains  $E$  and is closed under application of function symbols, substitution of terms for variables and bijective renaming of names. We write  $M =_E N$  when the equation  $M = N$  is in the theory  $E$ , and keep the signature implicit. When  $E$  is clear from its usage, we may abbreviate  $M =_E N$  as  $M = N$ . The negation of  $M =_E N$  is denoted  $M \neq_E N$  (and similarly abbreviated  $M \neq N$ ).

*Processes* and *extended processes* are defined in the usual way (Figure 2). We write  $\nu \tilde{u}$  for the (possibly empty) series of pairwise-distinct binders  $\nu u_1. \dots \nu u_l$ . The active substitution  $\{M/x\}$  can replace the variable  $x$  for the term  $M$  in every process it comes into contact with and this behaviour can be controlled by restriction, in particular, the process  $\nu x.(\{M/x\} \mid P)$  corresponds exactly to let  $x = M$  in  $P$ . Arbitrarily large active substitutions can be obtained by parallel composition and we occasionally abbreviate  $\{M_1/x_1\} \mid \dots \mid \{M_l/x_l\}$  as  $\{M_1/x_1, \dots, M_l/x_l\}$  or  $\{\tilde{M}/\tilde{x}\}$ . We also use  $\sigma$  and  $\tau$  to range over active substitutions, and write  $N\sigma$  for the result of applying  $\sigma$  to the free variables of  $N$ . Extended processes must have at most one active substitution for each variable and there is exactly one when the variable is under restriction. The only minor change compared to [1] is that conditional branches now depend on formulae

**Figure 2** Syntax for processes

$P, Q, R ::=$	(plain) processes
$0$	null process
$P \mid Q$	parallel composition
$!P$	replication
$\nu n.P$	name restriction
if $\phi$ then $P$ else $Q$	conditional
$u(x).P$	message input
$\bar{u}\langle M \rangle.P$	message output
$A, B, C ::=$	extended processes
$P$	plain process
$A \mid B$	parallel composition
$\nu n.A$	name restriction
$\nu x.A$	variable restriction
$\{M/x\}$	active substitution

$\phi, \psi ::= M = N \mid M \neq N \mid \phi \wedge \psi$ . If  $M$  and  $N$  are ground, we define  $\llbracket M = N \rrbracket$  to be **true** if  $M =_E N$  and **false** otherwise. The semantics of  $\llbracket \_ \rrbracket$  is then extended to formulae in the standard way.

The *scope* of names and variables are delimited by binders  $u(x)$  and  $\nu u$ . The set of bound names is written  $\text{bn}(A)$  and the set of bound variables is written  $\text{bv}(A)$ ; similarly we define the set of free names  $\text{fn}(A)$  and free variables  $\text{fv}(A)$ . Occasionally, we write  $\text{fn}(M)$  (and  $\text{fv}(M)$  respectively) for the set of names (and respectively variables) which appear in term  $M$ . An extended process is *closed* when every variable  $x$  is either bound or defined by an active substitution.

We define a *context*  $C[\_]$  to be an extended process with a hole. We obtain  $C[A]$  as the result of filling  $C[\_]$ 's hole with the extended process  $A$ . An *evaluation context* is a context whose hole is not in the scope of a replication, a conditional, an input, or an output. A context  $C[\_]$  closes  $A$  when  $C[A]$  is closed.

A *frame*, denoted  $\varphi$  or  $\psi$ , is an extended process built from the null process  $0$  and active substitutions  $\{M/x\}$ , which are composed by parallel composition and restriction. The *domain*  $\text{dom}(\varphi)$  of a frame  $\varphi$  is the set of variables that  $\varphi$  exports, that is, the set of variables  $x$  for which  $\varphi$  contains an active substitution  $\{M/x\}$  such that  $x$  is not under restriction. Every extended process  $A$  can be mapped to a frame  $\varphi(A)$  by replacing every plain process in  $A$  with  $0$ .

### 5.1.1 Operational semantics

The operational semantics are defined by three relations: *structural equivalence* ( $\equiv$ ), *internal reduction* ( $\rightarrow$ ), and *labelled reduction* ( $\xrightarrow{\alpha}$ ). These relations satisfy the rules in Figure 3 and are defined such that: structural equivalence is the smallest equivalence relation on extended processes that is closed by  $\alpha$ -

---

**Figure 3** Semantics for processes
 

---

PAR-0	$A \equiv A \mid 0$
PAR-A	$A \mid (B \mid C) \equiv (A \mid B) \mid C$
PAR-C	$A \mid B \equiv B \mid A$
REPL	$!P \equiv P \mid !P$
NEW-0	$\nu n.0 \equiv 0$
NEW-C	$\nu u.\nu w.A \equiv \nu w.\nu u.A$
NEW-PAR	$A \mid \nu u.B \equiv \nu u.(A \mid B)$ where $u \notin \text{fv}(A) \cup \text{fn}(A)$
ALIAS	$\nu x.\{M/x\} \equiv 0$
SUBST	$\{M/x\} \mid A \equiv \{M/x\} \mid A\{M/x\}$
REWRITE	$\{M/x\} \equiv \{N/x\}$ where $M =_E N$
COMM	$\bar{c}\langle x \rangle.P \mid c(x).Q \rightarrow P \mid Q$
THEN	if $\phi$ then $P$ else $Q \rightarrow P$ if $\llbracket \phi \rrbracket = \text{true}$
ELSE	if $\phi$ then $P$ else $Q \rightarrow Q$ otherwise
IN	$c(x).P \xrightarrow{c(M)} P\{M/x\}$
OUT-ATOM	$\bar{c}\langle u \rangle.P \xrightarrow{\bar{c}\langle u \rangle} P$
OPEN-ATOM	$\frac{A \xrightarrow{\bar{c}\langle u \rangle} A' \quad u \neq c}{\nu u.A \xrightarrow{\nu u.\bar{c}\langle u \rangle} A'}$
SCOPE	$\frac{A \xrightarrow{\alpha} A' \quad u \text{ does not occur in } \alpha}{\nu u.A \xrightarrow{\alpha} \nu u.A'}$
PAR	$\frac{A \xrightarrow{\alpha} A' \quad \text{bv}(\alpha) \cap \text{fv}(B) = \text{bn}(\alpha) \cap \text{fn}(B) = \emptyset}{A \mid B \xrightarrow{\alpha} A' \mid B}$
STRUCT	$\frac{A \equiv B \quad B \xrightarrow{\alpha} B' \quad B' \equiv A'}{A \xrightarrow{\alpha} A'}$

---

conversion of both bound names and bound variables, and closed under application of evaluation contexts; internal reduction is the smallest relation on extended processes closed under structural equivalence and application of evaluation contexts; and for labelled reductions  $\alpha$  is a *label* of the form  $c(M)$ ,  $\bar{c}\langle u \rangle$ , or  $\nu u.\bar{c}\langle u \rangle$  such that  $u$  is either a channel name or a variable of base type.

### 5.1.2 Equivalence

The definition of observational equivalence [1] quantifies over all contexts which makes proofs difficult, therefore we adopt labelled bisimilarity in this article. Labelled bisimilarity relies on an equivalence relation between frames, called static equivalence.

**Definition 1** (Static equivalence). *Two closed frames  $\varphi$  and  $\psi$  are statically equivalent, denoted  $\varphi \approx_s \psi$ , if  $\text{dom}(\varphi) = \text{dom}(\psi)$  and there exists a set of names  $\tilde{n}$  and substitutions  $\sigma, \tau$  such that  $\varphi \equiv \nu \tilde{n}.\sigma$  and  $\psi \equiv \nu \tilde{n}.\tau$  and for all terms  $M, N$  such that  $\tilde{n} \cap (\text{fn}(M) \cup \text{fn}(N)) = \emptyset$ , we have  $M\sigma =_E N\sigma$  holds if and only if  $M\tau =_E N\tau$  holds. Two closed extended processes  $A, B$  are statically equivalent, written  $A \approx_s B$ , if their frames are statically equivalent; that is,  $\varphi(A) \approx_s \varphi(B)$ .*

The relation  $\approx_s$  is called *static* equivalence because it only examines the current state of the processes, and not the processes' dynamic behaviour. The following definition of labelled bisimilarity captures the dynamic part.

**Definition 2** (Labelled bisimilarity). *Labelled bisimilarity ( $\approx_l$ ) is the largest symmetric relation  $\mathcal{R}$  on closed extended processes such that  $A \mathcal{R} B$  implies:*

1.  $A \approx_s B$ ;
2. if  $A \rightarrow A'$ , then  $B \rightarrow^* B'$  and  $A' \mathcal{R} B'$  for some  $B'$ ;
3. if  $A \xrightarrow{\alpha} A'$  such that  $\text{fv}(\alpha) \subseteq \text{dom}(A)$  and  $\text{bn}(\alpha) \cap \text{fn}(B) = \emptyset$ , then  $B \rightarrow^* \xrightarrow{\alpha} \rightarrow^* B'$  and  $A' \mathcal{R} B'$  for some  $B'$ .

Definitions of observational equivalence and labelled bisimilarity have been shown to coincide [58].

## 5.2 Modelling Helios in applied pi

We start by constructing a suitable signature  $\Sigma$  to capture the cryptographic primitives used by Helios and define an equational theory  $E$  to capture the relationship between these primitives.

### 5.2.1 Signature

We adopt the following signature.

$$\Sigma = \{\text{ok}, \text{zero}, \text{one}, \perp, \text{fst}, \text{snd}, \text{pair}, *, +, \circ, \text{partial}, \text{checkspk}, \text{penc}, \text{spk}, \text{dec}\}$$

Functions `ok`, `zero`, `one`,  `$\perp$`  are constants; `fst`, `snd` are unary functions; `dec`, `pair`, `partial`, `*`, `+`,  `$\circ$`  are binary functions; `checkspk`, `penc` are ternary functions; and `spk` is a function of arity four. We adopt infix notation for `*`, `+`, and  `$\circ$` .

The term `penc( $T, N, M$ )` denotes the encryption of plaintext  $M$ , using random nonce  $N$  and key  $T$ . The term  `$U * U'$`  denotes the homomorphic combination of ciphertexts  $U$  and  $U'$ , the corresponding operation on plaintexts is written

$M + M'$  and  $N \circ N'$  on nonces. The partial decryption of ciphertext  $U$  using key  $L$  is denoted  $\text{partial}(L, U)$ . The term  $\text{spk}(T, N, M, U)$  represents a signature of knowledge that proves  $U$  is a ciphertext under the public key  $T$  on the plaintext  $M$  using nonce  $N$  and such that  $M$  is either the constant  $\text{zero}$  or  $\text{one}$ . We introduce tuples using pairings and, for convenience, we occasionally abbreviated  $\text{pair}(M_1, \text{pair}(\dots, \text{pair}(M_n, \perp)))$  as  $(M_1, \dots, M_n)$ , and  $\text{fst}(\text{snd}^{i-1}(M))$  is denoted  $\pi_i(M)$ , where  $i \in \mathbb{N}$ . We use the equational theory  $E$  that asserts functions  $+$ ,  $*$ ,  $\circ$  are commutative and associative, and includes the equations:

$$\text{fst}(\text{pair}(x, y)) = x \quad (\text{E1})$$

$$\text{snd}(\text{pair}(x, y)) = y \quad (\text{E2})$$

$$\text{zero} + \text{one} = \text{one} \quad (\text{E3})$$

$$\text{zero} + \text{zero} = \text{zero} \quad (\text{E4})$$

$$\text{dec}(x_{\text{sk}}, \text{penc}(\text{pk}(x_{\text{sk}}), x_{\text{rand}}, x_{\text{plain}})) = x_{\text{plain}} \quad (\text{E5})$$

$$\text{dec}(\text{partial}(x_{\text{sk}}, \text{ciph}), \text{ciph}) = x_{\text{plain}} \quad (\text{E6})$$

$$\text{where } \text{ciph} = \text{penc}(\text{pk}(x_{\text{sk}}), x_{\text{rand}}, x_{\text{plain}})$$

$$\text{penc}(x_{\text{pk}}, y_{\text{rand}}, y_{\text{plain}}) * \text{penc}(x_{\text{pk}}, z_{\text{rand}}, z_{\text{plain}}) \quad (\text{E7})$$

$$= \text{penc}(x_{\text{pk}}, y_{\text{rand}} \circ z_{\text{rand}}, y_{\text{plain}} + z_{\text{plain}})$$

$$\text{checkspk}(x_{\text{pk}}, \text{ball}, \text{spk}(x_{\text{pk}}, x_{\text{rand}}, \text{zero}, \text{ball})) = \text{ok} \quad (\text{E8})$$

$$\text{where } \text{ball} = \text{penc}(x_{\text{pk}}, x_{\text{rand}}, \text{zero})$$

$$\text{checkspk}(x_{\text{pk}}, \text{ball}, \text{spk}(x_{\text{pk}}, x_{\text{rand}}, \text{one}, \text{ball})) = \text{ok} \quad (\text{E9})$$

$$\text{where } \text{ball} = \text{penc}(x_{\text{pk}}, x_{\text{rand}}, \text{one})$$

Equation E6 allows plaintext  $M$  to be recovered from ciphertext  $\text{penc}(\text{pk}(L), N, M)$  given partial decryption  $\text{partial}(L, \text{penc}(\text{pk}(L), N, M))$ , when the partial decryption is constructed using the private key  $L$ . Equation E7 represents the homomorphic combination of ciphertexts. The Equations E8 and E9 allow the verification of signatures of knowledge  $\text{spk}(T, N, M, \text{penc}(T, N, M))$ , when  $M \in \{\text{zero}, \text{one}\}$ . The remaining equations are standard.

**Example 1.** *Given randomness  $N, N'$ , plaintexts  $(M, M') \in \{(\text{zero}, \text{zero}), (\text{zero}, \text{one}), (\text{one}, \text{zero})\}$ , and public key  $T$ , one can construct a signature of knowledge  $L = \text{spk}(T, N \circ N', M + M', \text{penc}(T, N, M) * \text{penc}(T, N', M'))$ . Then  $\text{checkspk}$  applied to the public key  $T$ , the homomorphically combined ciphertexts  $\text{penc}(T, N, M) * \text{penc}(T, N', M')$ , and the signature  $L$  is equal to  $\text{ok}$  using Equations E3, E7, E8, and E9*

### 5.2.2 Helios process specification

In the applied pi calculus, it is sufficient to model the parts of the voting system which need to be trusted for ballot secrecy; all the remaining parts of the system are controlled by the adversarial environment. Accordingly, we assume the

existence of at least two honest voters  $\mathcal{A}, \mathcal{B}$ ; since this avoids the scenario where ballot secrecy of an individual voter is compromised by collusion amongst all the remaining voters. In addition, the following trust assumptions are required.

- At least one trustee is honest
- The election officer runs the bulletin board honestly:
  - Voters  $\mathcal{A}, \mathcal{B}$  have authentic channels with the bulletin board
  - Signatures of knowledge are checked for dishonest voters\*
  - Replays of honest ballots (that is, those cast by  $\mathcal{A}$  or  $\mathcal{B}$ ) are rejected\*
  - The tally is correctly computed\*
  - The trustees have an authentic channel with the bulletin board
- The browser script is trusted and has the correct public key of the election

(Assumptions marked with \* could be performed by an honest trustee, rather than the bulletin board.) Although neither voters nor observers can verify that there exists an honest trustee, an assurance of trust is provided by distribution. The necessity to trust the election officer to run the bulletin board is less desirable and work-in-progress [64] aims to weaken this assumption; moreover, to further distribute trust assumptions, the trustees could also check signatures and tallying. Finally, trust in the browser script can be obtained by using software written by a reputable source or writing your own code.

The trusted components are modelled by the administration process  $A_{\ell,n}^\phi$  and voting process  $V_\ell$  defined in Figure 4. For generality, the voting process  $V_\ell$  is parametrised by the number of candidates  $\ell$ . Similarly, the administration process  $A_{\ell,n}^\phi$  is parametrised by the number of candidates  $\ell$ , the number of voters  $n$ , and a formula  $\phi$ ; the formula  $\phi$  defines the checks performed by the bulletin board before accepting a ballot. We will consider several variants of Helios (including the original Helios 2.0 protocol and our fixed scheme) by considering suitable formula that we call *Helios process specifications*.

**Definition 3** (Helios process specification). *A formula  $\phi_{\ell,\bar{n}}$  is a Helios process specification, if  $\text{fv}(\phi_{\ell,\bar{n}}) \subseteq \{y_1, \dots, y_{\bar{n}}, y_{\text{ballot}}, z_{\text{pk}}\}$ .*

The voting process  $V_\ell$  contains free variables  $x_1^{\text{vote}}, \dots, x_\ell^{\text{vote}}$  to represent the voter’s vote (which is expected to be encoded using constants **zero** and **one**) and the free variable  $x_{\text{auth}}$  represents the channel shared by the voter and the bulletin board. The definition of the process  $V_\ell$  corresponds to the description of the browser script (Figure 1). The administration process  $A_{\ell,n}^\phi$  is parametrised by the number of candidates  $\ell$ , the number of voters  $n$ , and a Helios process specification  $\phi$ . The restricted name  $sk_T$  models the tallier’s secret key and the public part  $\text{pk}(sk_T)$  is included in the process’s frame. The restricted names  $a_1$  and  $a_2$  model authentic channels between the two honest voters and the bulletin board, and the channel name  $d$  captures the authentic channel with the honest

---

**Figure 4** Helios process specification

---

Let  $\ell$  be some number of candidates,  $n \geq 2$  be some number of voters, and  $\phi$  be a Helios process specification. The administration process  $A_{\ell,n}^\phi$  and voting process  $V_\ell$  are defined below.

$$\begin{aligned}
V_\ell &= \nu r_1 . \\
&\quad \text{let } ciph_1 = \text{penc}(z_{\text{pk}}, r_1, x_1^{\text{vote}}) \text{ in} \\
&\quad \text{let } spk_1 = \text{spk}(z_{\text{pk}}, r_1, x_1^{\text{vote}}, ciph_1) \text{ in} \\
&\quad \vdots \\
&\quad \nu r_\ell . \\
&\quad \text{let } ciph_\ell = \text{penc}(z_{\text{pk}}, r_\ell, x_\ell^{\text{vote}}) \text{ in} \\
&\quad \text{let } spk_\ell = \text{spk}(z_{\text{pk}}, r_\ell, x_\ell^{\text{vote}}, ciph_\ell) \text{ in} \\
&\quad \text{let } \hat{r} = r_1 \circ \dots \circ r_\ell \text{ in} \\
&\quad \text{let } \widehat{ciph} = ciph_1 * \dots * ciph_\ell \text{ in} \\
&\quad \text{let } \widehat{vote} = x_1^{\text{vote}} + \dots + x_\ell^{\text{vote}} \text{ in} \\
&\quad \text{let } \widehat{spk} = \text{spk}(z_{\text{pk}}, \hat{r}, \widehat{vote}, \widehat{ciph}) \text{ in} \\
&\quad \overline{x_{\text{auth}}} \langle \langle ciph_1, \dots, ciph_\ell, spk_1, \dots, spk_\ell, \widehat{spk} \rangle \rangle \\
\\
A_{\ell,n}^\phi &= \nu sk_T, a_1, a_2, d . (- \mid BB_{\ell,n}^\phi \mid T_\ell \mid \{\text{pk}(sk_T)/z_{\text{pk}}\}) \\
\\
BB_{\ell,n}^\phi &= a_1(y_1) . \bar{c}\langle y_1 \rangle . a_2(y_2) . \bar{c}\langle y_2 \rangle . \\
&\quad a_3(y_3) . \text{if } \phi_{\ell,2}\{y_3/y_{\text{ballot}}\} \text{ then} \\
&\quad \dots a_n(y_n) . \text{if } \phi_{\ell,n-1}\{y_n/y_{\text{ballot}}\} \text{ then} \\
&\quad \text{let } tally_1 = \pi_1(y_1) * \dots * \pi_1(y_n) \text{ in} \\
&\quad \dots \text{let } tally_\ell = \pi_\ell(y_1) * \dots * \pi_\ell(y_n) \text{ in} \\
&\quad \bar{d}\langle \langle tally_1, \dots, tally_\ell \rangle \rangle . \\
&\quad d(y_{\text{partial}}) . \\
&\quad \bar{c}\langle y_{\text{partial}} \rangle . \\
&\quad \bar{c}\langle \langle \text{dec}(\pi_1(y_{\text{partial}}), tally), \dots, \text{dec}(\pi_\ell(y_{\text{partial}}), tally') \rangle \rangle \\
\\
T_\ell &= d(y_{\text{tally}}) . \\
&\quad \bar{d}\langle \langle \text{partial}(sk_T, \pi_1(y_{\text{tally}})), \dots, \text{partial}(sk_T, \pi_\ell(y_{\text{tally}})) \rangle \rangle
\end{aligned}$$

---

trustee. To ensure the adversary has access to messages sent on private channels, communication is relayed on the public channel  $c$ . The sub-process  $BB_{\ell,n}^\phi$  represents the bulletin board and  $T_\ell$  represents the tallier. The bulletin board accepts ballots from each voter and checks they are valid using the Helios process specification  $\phi$  (this predicate will be discussed in more detail below). Once all ballots have been submitted, the bulletin board homomorphically combines the ciphertexts and sends the encrypted tallies to the tallier for decryption. (The necessity for all voters to participate is included for simplicity, in particular, our bulletin board does not weed ballots containing invalid proofs.) The tallier

receives the homomorphic combinations of ballots  $y_{\text{tally}}$  and derives a partial decryption for each candidate; these partial decryptions are sent to the bulletin board and the election result is published.

The voting process  $V_\ell$  is parameterised by a substitution  $\sigma$ , where variables  $x_1^{\text{vote}}, \dots, x_\ell^{\text{vote}} \in \text{dom}(\sigma)$ ; these variables must be parameterised to encode a vote for at most one candidate, that is, there exists at most one integer  $i \in \{1, \dots, \ell\}$  such that  $\Sigma \vdash x_i^{\text{vote}} \sigma = \text{one}$ . Formally, we define valid parameterisations using the notion of *candidate substitutions*.

**Definition 4** (Candidate substitution). *Given some number of candidates  $\ell$  and a substitution  $\sigma$ , we say  $\sigma$  is a candidate substitution if*

$$\Sigma \vdash (x_1^{\text{vote}} + \dots + x_\ell^{\text{vote}}) \sigma = \text{zero} \vee \Sigma \vdash (x_1^{\text{vote}} + \dots + x_\ell^{\text{vote}}) \sigma = \text{one}$$

It follows immediately that bitstrings  $m_1, \dots, m_\ell$  generated during Step 2 of Figure 1 can be modelled as candidate substitutions.

The application of our model is demonstrated in the following example.

**Example 2.** *Let  $\ell$  be some number of candidates,  $n \geq 2$  be some number of voters, and  $\phi$  be a Helios process specification. An election with voters  $\mathcal{A}$  and  $\mathcal{B}$  who select candidate substitutions  $\sigma$  and  $\tau$ , and such that the other  $n - 2$  voters are controlled by the adversary, can be modelled by the process  $A_{\ell, n}^\phi [V_\ell\{a_1/x_{\text{auth}}\}\sigma \mid V_\ell\{a_2/x_{\text{auth}}\}\tau]$ .*

**Ballot validity.** In Helios 2.0, the election officer considers a ballot to be valid if the signature proofs of knowledge hold. Accordingly, we can model the Helios administration by the process  $A_{\ell, n}^{\phi^{\text{orig}}}$  where the Helios process specification  $\phi^{\text{orig}}$ , parameterised by the number of candidates  $\ell$ , is defined as follows.

$$\begin{aligned} \phi_\ell^{\text{orig}} \triangleq & \text{checkspk}(z_{\text{pk}}, \pi_1(y_{\text{ballot}}) * \dots * \pi_\ell(y_{\text{ballot}}), \pi_{2 \cdot \ell + 1}(y_{\text{ballot}})) = \text{ok} \wedge \\ & \text{checkspk}(z_{\text{pk}}, \pi_1(y_{\text{ballot}}), \pi_{\ell + 1}(y_{\text{ballot}})) = \text{ok} \wedge \dots \wedge \\ & \text{checkspk}(z_{\text{pk}}, \pi_\ell(y_{\text{ballot}}), \pi_{2 \cdot \ell}(y_{\text{ballot}})) = \text{ok} \end{aligned}$$

We have shown that these checks are insufficient to ensure ballot secrecy (Section 3). Our weeding replayed ballots solution, proposed in Section 4.1, additionally requires that the ciphertexts inside the ballot do not appear on the bulletin board. This revised scheme can be modelled using the Helios process specification  $\phi^{\text{sol}}$ , parameterised by the number of candidates  $\ell$  and number of ballots already on the bulletin board  $\bar{n}$ , defined as follows.

$$\phi_{\ell, \bar{n}}^{\text{sol}} \triangleq \phi_\ell^{\text{orig}} \wedge \pi_{2 \cdot \ell + 2}(y_{\text{ballot}}) = \perp \wedge \bigwedge_{\substack{i, j \in \{1, \dots, \ell\}, \\ k \in \{1, \dots, \bar{n}\}}} \pi_i(y_k) \neq \pi_j(y_{\text{ballot}})$$

We can also model a naïve solution that would consist in weeding only identical ballots by considering the Helios process specification  $\phi^{\text{ident}}$ , parameterised by

the number of candidates  $\ell$  and number of ballots already on the bulletin board  $\bar{n}$ , defined below.

$$\phi_{\ell, \bar{n}}^{\text{ident}} \triangleq \phi_{\ell}^{\text{orig}} \wedge \pi_6(y_{\text{ballot}}) = \perp \wedge \bigwedge_{k \in \{1, \dots, \bar{n}\}} y_{\text{ballot}} \neq y_k$$

We have already shown that removing exact duplicates is insufficient because it would fail to detect variants of our attack whereby the contents of a ballot are permuted. In the next section, we formally show that Helios 2.0 (modelled using  $\phi^{\text{orig}}$ ) and the naïve solution (modelled using  $\phi^{\text{ident}}$ ) do not satisfy ballot secrecy, and that our proposed solution (modelled using  $\phi^{\text{sol}}$ ) does satisfy ballot secrecy.

### 5.3 Formal analysis: Ballot secrecy

Based upon [49, 30, 31], and as previous discussed (see *related work* in Section 1), we formalise ballot secrecy for two voters  $\mathcal{A}$  and  $\mathcal{B}$  with the assertion that an adversary cannot distinguish between a situation in which voter  $\mathcal{A}$  votes for candidate  $t$  and voter  $\mathcal{B}$  votes for candidate  $t'$ , from another situation in which  $\mathcal{A}$  votes  $t'$  and  $\mathcal{B}$  votes  $t$ . Formally, this is captured by Definition 5.

**Definition 5** (Ballot secrecy). *Given a Helios process specification  $\phi$ , we say ballot secrecy is satisfied if for all integers  $\ell \in \mathbb{N}^*$  and  $n \geq 2$ , and for all candidates substitutions  $\sigma$  and  $\tau$ , we have*

$$A_{\ell, n}^{\phi} [V_{\ell}\{a_1/x_{\text{auth}}\}\sigma \mid V_{\ell}\{a_2/x_{\text{auth}}\}\tau] \approx_l A_{\ell, n}^{\phi} [V_{\ell}\{a_1/x_{\text{auth}}\}\tau \mid V_{\ell}\{a_2/x_{\text{auth}}\}\sigma]$$

The ballot secrecy definition proposed by Delaune, Kremer & Ryan considered a vote to be an arbitrary name, whereas a vote in our setting must be a series of the constant symbols **zero** and **one**, such that their combination by application of the function  $+$  is also a constant **zero** and **one**; it follows that Definition 5 is a straightforward variant of the original.

The Helios 2.0 protocol does not satisfy our privacy definition (Lemma 1) and naïve ballot weeding solutions are also insufficient (Lemma 2).

**Lemma 1.** *The Helios process specification  $\phi^{\text{orig}}$  does not satisfy ballot secrecy.*

Intuitively, the proof of Lemma 1 is due to the environment’s ability to replay  $\mathcal{A}$ ’s ballot, therefore introducing an observable difference: the result will include two instances of  $\mathcal{A}$ ’s vote. Formally, this follows immediately from the proof Lemma 2.

**Lemma 2.** *The Helios process specification  $\phi^{\text{ident}}$  does not satisfy ballot secrecy.*

*Proof.* Consider  $\ell = 2$ ,  $n = 3$ ,  $\sigma = \{\text{zero}/x_1^{\text{vote}}, \text{one}/x_2^{\text{vote}}\}$  and  $\tau = \{\text{one}/x_1^{\text{vote}}, \text{zero}/x_2^{\text{vote}}\}$ . We consider a sequence of transitions where the two voters output their ballots and then the adversary chooses its ballots to be a permutation of the first voter’s ballot. Namely, if the first voter’s ballot is  $(\text{ciph}, \text{ciph}', \text{spk}, \text{spk}', \widehat{\text{spk}})$  then the adversary outputs  $(\text{ciph}', \text{ciph}, \text{spk}', \text{spk}, \widehat{\text{spk}})$ . Formally, this corresponds to the following transitions

$$\begin{aligned}
& A_{\ell,n}^\phi [V_\ell\{a_1/x_{\text{auth}}\}\sigma \mid V_\ell\{a_2/x_{\text{auth}}\}\tau] \\
& \quad \rightarrow \xrightarrow{\nu x.\bar{c}\langle x \rangle} \xrightarrow{\nu y.\bar{c}\langle y \rangle} c(\langle \pi_2(x), \pi_1(x), \pi_4(x), \pi_3(x), \pi_5(x) \rangle) \rangle \rightarrow^* \xrightarrow{\nu z.\bar{c}\langle z \rangle} \nu \tilde{n}.\tau_1
\end{aligned}$$

for some names  $\tilde{n}$  and substitution  $\tau_1$ , such that:

$$\text{dec}(\pi_1(z), \pi_1(x) * \pi_1(y) * \pi_2(x))\tau_1 =_E \text{one} + \text{one}$$

This labeled transition has to be matched by

$$\begin{aligned}
& A_{\ell,n}^\phi [V_\ell\{a_1/x_{\text{auth}}\}\tau \mid V_\ell\{a_2/x_{\text{auth}}\}\sigma] \\
& \quad \rightarrow \xrightarrow{\nu x.\bar{c}\langle x \rangle} \xrightarrow{\nu y.\bar{c}\langle y \rangle} c(\langle \pi_2(x), \pi_1(x), \pi_4(x), \pi_3(x), \pi_5(x) \rangle) \rangle \rightarrow^* \xrightarrow{\nu z.\bar{c}\langle z \rangle} \nu \tilde{n}.\tau_2
\end{aligned}$$

for some names  $\tilde{n}$  and substitution  $\tau_2$ , such that:

$$\text{dec}(\pi_1(z), \pi_1(x) * \pi_1(y) * \pi_2(x))\tau_2 =_E \text{one}$$

It follows immediately that  $\nu \tilde{n}.\tau_1 \not\approx_s \nu \tilde{n}.\tau_2$  and, hence,  $\phi^{\text{ident}}$  does not satisfy ballot secrecy.  $\square$

In contrast, removing duplicates up to permutation ensures ballot secrecy.

**Theorem 1.** *The Helios process specification  $\phi^{\text{sol}}$  satisfies ballot secrecy.*

ProVerif is an automatic tool that can check equivalence in the applied pi calculus [16]. Although ProVerif has been successfully used to prove ballot secrecy (for example, in the Fujioka, Okamoto & Ohta protocol [33]), it cannot prove Theorem 1, at the time of writing, for two main reasons. Firstly, ProVerif cannot prove equivalences under the homomorphic equation (Equation E7). Secondly, our theorem states ballot secrecy for any number  $n$  of participants and ProVerif cannot handle parametrised processes (see Paiola & Blanchet [61, 60] for some initial progress in this direction). We proceed by constructing a relation that relates  $A_{\ell,n}^\phi [V_\ell\{a_1/x_{\text{auth}}\}\sigma \mid V_\ell\{a_2/x_{\text{auth}}\}\tau]$  and  $A_{\ell,n}^\phi [V_\ell\{a_1/x_{\text{auth}}\}\tau \mid V_\ell\{a_2/x_{\text{auth}}\}\sigma]$ , and all their successors, such that it satisfies the three properties of Definition 2. In particular, the two final frames (containing the result of the election) should be statically equivalent.

**Definition 6** (Valid ballot). *A term  $T$  is said to be a valid ballot in an election with  $\ell$  candidates if  $\llbracket \phi_{\ell,0}^{\text{sol}}\{T/y_{\text{ballot}}\} \rrbracket = \text{true}$ .*

By definition, the bulletin board accepts only valid ballots. A key step to proving static equivalence is to show that any valid ballot submitted to the bulletin board by the environment is “equivalent” to a term of the form  $(\text{penc}(z_{\text{pk}}, N_1, M_1), \dots, \text{penc}(z_{\text{pk}}, N_\ell, M_\ell), S_1, \dots, S_{\ell+1})$ , where  $\{M_1/x_1^{\text{vote}}, \dots, M_\ell/x_\ell^{\text{vote}}\}$  is a candidate substitution. This allows us to deduce that the election outcome produced by  $A_{\ell,n}^\phi [V_\ell\{a_1/x_{\text{auth}}\}\sigma \mid V_\ell\{a_2/x_{\text{auth}}\}\tau]$  is exactly the same as in  $A_{\ell,n}^\phi [V_\ell\{a_1/x_{\text{auth}}\}\tau \mid V_\ell\{a_2/x_{\text{auth}}\}\sigma]$ . We can then conclude the proof of Theorem 1 by showing that the partial decryptions and the encrypted ballots of honest voters do not leak any extra information to the adversary. The full proof appears in Appendix B.

## 5.4 Limitations

The limitations of our model, which we introduced to simplify the presentation and proof, are detailed below; we believe a full security proof should follow using similar reasoning. We make use of a (standard) definition of ballot secrecy which is limited to elections with two honest voters [49, 30, 31]. In addition, the definition of ballot secrecy does not consider parallel composition of protocol executions and we therefore recommend using distinct keys for each election (although we believe it should be sufficient to include an election identifier – for example, the election fingerprint – in the challenge hashes included within signatures of knowledge, similar to the methodology in Section 4.2). The administrative process  $A_{\ell,n}^\phi$  enforces an ordering on voters (namely, the voter using private channel  $a_1$  must vote first, followed by the voter using private channel  $a_2$ , and then any remaining voters – controlled by the adversarial environment – can vote); this limitation could be overcome by parameterising  $A_{\ell,n}^\phi$  with the channel names to restrict and by a minor unification of the bulletin process  $BB_{\ell,n}^\phi$ , however, this generalisation is of limited interest and would come at the cost of over-complicating the proof. In addition, the administrative process  $A_{\ell,n}^\phi$  does not permit revoting. The signature and equational theory do not capture low-level technical details surrounding the correct construction of public keys; in particular, we do not use signatures of knowledge to verify correct key construction. We also omit signatures of knowledge that demonstrate correct construction of partial decryptions. Finally, we offer the usual caveat to formal analysis and acknowledge that our result does not imply the absence of real-world attacks (see, for example, [69, 2, 3, 81, 82]). It may, therefore, be possible to modify the ballot in a way that would not be captured by our analysis. (In particular, it is important to notice that the scheme used for signatures of knowledge is not provably non-malleable.) We partly overcome these limitations in our complimentary work [15] by presenting a variant of Helios that is provably secure in a cryptographic setting.

## 6 Attacks against other schemes

This section demonstrates that the absence of ballot independence can be exploited in other electronic voting protocols to violate privacy. In particular, we demonstrate replay attacks against schemes by Sako & Kilian [70] and Schoenmakers [72], both of which were presented at CRYPTO, and we show that the malleable cryptographic scheme adopted by Lee *et al.* [55] can be exploited to launch attacks. In addition, perhaps contrary to intuition, we will argue that no general relationships exist between independence and privacy properties.

### 6.1 Exploiting replays in the protocol by Sako & Kilian

The Sako & Kilian [70] electronic voting scheme capitalises upon advances in cryptography to improve the Banaloh & Yung protocol [14]. The scheme is interesting because it was one of the first electronic voting protocols to adopt the

Fiat-Shamir heuristic to derive non-interactive proofs (this evolution was key for the development of end-to-end verifiable electronic voting systems). However, we will show that the application of the Fiat-Shamir heuristic compromises ballot secrecy. In particular, the interactive nature of zero-knowledge proofs guarantees ballot independence; whereas, non-interactive proofs, derived using the Fiat-Shamir heuristic, do not assure independence. This can be exploited by a replay attack to violate ballot secrecy.

### 6.1.1 Protocol description

The scheme is based upon a pair of *partially compatible homomorphic encryption* functions, that is, a pair of functions  $f_1, f_2$  over  $\mathbb{Z}_q$ , where  $q$  is prime, such that for all  $i, j \in \{1, 2\}$  the following properties are satisfied:

- $f_i(x + y) = f_i(x) \cdot f_i(y)$ , where  $x, y \in \mathbb{Z}_q$
- Distributions  $(f_i(x), f_j(y))$  and  $(f_i(x), f_j(x))$  are computationally indistinguishable, where  $x$  and  $y$  are chosen uniformly in  $\mathbb{Z}_q$ .

The voting protocol is defined for  $m \in \mathbb{N}$  voters as follows.

**Setup.** Talliers  $\mathcal{T}$  and  $\mathcal{T}'$  publish public keys  $k$  and  $k'$  for a public key encryption scheme  $E$  (which need not be homomorphic).

**Voting.** Given vote  $v_i \in \{-1, 1\}$ , the voter generates nonces  $x_i, x'_i \in \mathbb{Z}_q$  such that  $v_i = x_i + x'_i$  and constructs her ballot as follows:

$$\begin{aligned} Y_i &= f_1(x_i) \\ Y'_i &= f_2(x'_i) \\ Z_i &= E(k, x_i) \\ Z'_i &= E(k', x'_i) \end{aligned}$$

In addition, the voter is required to prove  $x_i + x'_i \in \{1, -1\}$  in zero-knowledge. However, to avoid an interactive proof, the Fiat-Shamir heuristic is applied to derive a signature of knowledge  $\sigma_i$ . (For brevity we omit the construction of  $\sigma_i$ , see [70, Figure 1] for details.)

**Tallying.** Given ballots  $Y_1, Y'_1, Z_1, Z'_1, \sigma_1, \dots, Y_n, Y'_n, Z_n, Z'_n, \sigma_n$ , tallier  $\mathcal{T}$  decrypts each  $Z_i$  to recover  $\hat{x}_i$  and checks  $Y_i = f_1(\hat{x}_i)$ , similarly, tallier  $\mathcal{T}'$  decrypts  $Z'_i$  to recover  $\hat{x}'_i$  and checks  $Y'_i = f_2(\hat{x}'_i)$ ; the talliers also check the signature of knowledge  $\sigma_i$ . The talliers publish  $V = \sum_{i=1}^m \hat{x}_i$  and  $V' = \sum_{i=1}^m \hat{x}'_i$ , and the result is  $T = V + V'$ , which can be verified by checking  $f_1(V) = \prod_{i=1}^m Y_i$  and  $f_2(V') = \prod_{i=1}^m Y'_i$ .

### 6.1.2 Attacking ballot secrecy

We show that the voting protocol by Sako & Kilian does not satisfy ballot secrecy, by presenting a replay attack which allows an adversary to reveal a voter's vote. Intuitively, an adversary may observe the ballot posted by a particular voter and recast this ballot by corrupting dishonest voters. The multiple occurrences of the voter's ballot will leak information in the tally and the adversary can exploit this knowledge to violate the voter's privacy. An informal description of the attack will now be presented in the case of three eligible voters.

Let us consider an election with three eligible voters who have identities  $id_1$ ,  $id_2$  and  $id_3$ . Suppose that voters  $id_1$ ,  $id_2$  are honest and  $id_3$  is a dishonest voter controlled by the adversary. Further assume that the adversary has observed the ballot

$$Y_k, Y'_k, Z_k, Z'_k, \sigma_k$$

being cast by the voter whose privacy will be compromised.

**Exploiting the absence of ballot independence.** As shown by Gennaro [43], an adversary can replay the ballot  $Y_k, Y'_k, Z_k, Z'_k, \sigma_k$ , thereby violating ballot independence. (The violation of ballot independence is due to the adversary's ability to cast the *same* vote as the honest voter.) Since the ballot was constructed by an honest voter, it is trivial to see that it will be considered valid by the talliers. We will now show how the lack of ballot independence can be exploited to violate privacy.

**Violating privacy.** The bulletin board will be constructed as follows

$$Y_1, Y'_1, Z_1, Z'_1, \sigma_1, Y_2, Y'_2, Z_2, Z'_2, \sigma_2, Y_k, Y'_k, Z_k, Z'_k, \sigma_k, V, V'$$

where  $k \in \{1, 2\}$ ,  $V = x_1 + x_2 + x_k$  and  $V' = x'_1 + x'_2 + x'_k$ . It follows from the protocol description that  $v_i = x_i + x'_i$ , where  $i \in \{1, 2, k\}$ , and the result  $T = V + V' = v_1 + v_2 + v_k$ . Since there will be at least two votes for the candidate voter  $id_k$  voted for, the voter's vote can be revealed: if  $T \geq 2$ , then  $v_k = 1$ ; otherwise  $v_k = -1$ . It follows that the voter's privacy has been compromised; moreover, the vote of the remaining honest voter is  $T - 2 \cdot v_k$ .

### 6.1.3 Independence and the Fiat-Shamir heuristic

The interactive nature of zero-knowledge proofs guarantee independence; by comparison, non-interactive proofs, derived using the Fiat-Shamir heuristic, do not assure independence. As a consequence, application of the Fiat-Shamir heuristic may compromise the security of cryptographic protocols and we have shown how application of the heuristic erodes privacy in the electronic voting scheme by Sako & Kilian. This demonstrates that the use of the Fiat-Shamir heuristic requires some care and highlights the necessity for thorough security analysis.

#### 6.1.4 Generalising replay attacks

The replay attack against the voting protocol by Sako & Kilian can be generalised to other schemes where an adversary can observe a ballot cast by a particular voter and replay this ballot verbatim. In particular, the voting protocol by Schoenmakers [72] fits this description.

**Exploiting replays in the protocol by Schoenmakers.** The electronic voting protocol by Schoenmakers [72] is based upon [28, 29]. The scheme explicitly aims to provide efficient small-scale elections (for example, boardroom elections) and, given that our attack is particularly well suited to small-scale elections, we find it interesting to study the possibility of violating ballot secrecy in this setting. Ballot independence is not provided [72, §5] and we exploit privacy using a replay attack. The attack description is straightforward and follows immediately from our discussion; accordingly, we omit the details and refer the interested reader to our technical report [77, §3].

#### 6.1.5 Possible solutions: Weeding duplicate ballots

Our verbatim replay attacks against the voting protocols by Sako & Kilian and Schoenmakers exploit the possibility of replaying a voter’s ballot without detection. We believe it should be sufficient for the election officer to reject any duplicate ballots to ensure ballot secrecy, alternatively, the *binding ballots to voters* solution (Section 4.2) may also be suitable, although proving the security of these solutions remains an open problem.

### 6.2 Exploiting malleability in the protocol by Lee *et al.*

The Lee *et al.* [55] electronic voting scheme adopts an offline tamper-resistant hardware device to ensure receipt freeness; more precisely, the hardware device takes an ElGamal encrypted vote as input and outputs a re-encrypted ciphertext, this prevents a voter proving how she voted by reconstruction as she does not know the nonce introduced for re-encryption. In addition, the hardware device provides a Designated Verifier Proof of re-encryption, thereby allowing the voter to verify that the device behaved correctly. The device is assumed to be offline and, hence, communication between the voter and the device is assumed to be untappable.

#### 6.2.1 Background: Multiplicative homomorphic ElGamal

The scheme uses multiplicative homomorphic ElGamal, rather than the additive variant presented in Section 2.1. The operations for key generation, homomorphic combination and re-encryption are standard; albeit, the result of homomorphic combination is the multiplication of plaintexts, rather than the addition of plaintexts. We recall the operations for encryption and decryption below.

**Encryption.** Given a message  $m$  and a public key  $h$ , select a random nonce  $r \in_R \mathbb{Z}_q^*$  and derive the ciphertext  $(a, b) = (g^r \bmod p, m \cdot h^r \bmod p)$ .

**Distributed decryption.** Given a ciphertext  $(a, b)$ , each trustee  $i \in n$  computes the partial decryption  $k_i = a^{x_i}$ . The plaintext  $m = b / (k_1 \cdot \dots \cdot k_n) \bmod p$ .

The application of these primitives to derive the scheme by Lee *et al.* will be discussed in the next section.

### 6.2.2 Protocol description

An election is created by naming an election officer, selecting a set of mixers, and choosing a set of trustees. The trustees generate a distributed public key pair and the election officer publishes the public key on the bulletin board. (For robustness, threshold ElGamal may be used; we omit these details for brevity.) The election officer also publishes the candidate list, the public keys of eligible voters, and the public keys of the tamper-resistant hardware devices. Informally, the steps that the participants take during an election are as follows.

1. The voter constructs an ElGamal ciphertext  $(a, b)$  containing her vote  $v$  and sends the ciphertext to her tamper-resistant hardware device.
2. The hardware device re-encrypts the voter's ciphertext to produce  $(a', b')$  and computes a Designated Verifier Proof of re-encryption  $\tau$ . The device also derives a signature  $\sigma$  on the re-encryption. The hardware device returns  $(a', b'), \sigma, \tau$  to the voter.
3. If the signature and proof are valid, then the voter generates a signature  $\sigma'$  on the message  $\sigma$  using her private key. The voter submits her ballot  $(a', b'), \sigma, \sigma'$  to the bulletin board.
4. Individual voters can check that their ballots appear on the bulletin board and can be assured that the ciphertext  $(a', b')$  contains their vote  $v$  by verifying the Designated Verifier Proof  $\tau$ .
5. Voters and observers can check that ballots were cast by registered voters by verifying signatures  $\sigma'$ , and are assured that each voter cast at most one ballot by checking that no voter signed two values. In addition, voters and observers should verify signatures  $\sigma$  for receipt freeness.
6. After some predefined deadline, valid ballots (that is, ballots associated with valid signatures  $\sigma$  and  $\sigma'$ ) are submitted to the mixers. Anyone can check that mixing is performed correctly.
7. Each of the trustees publishes a partial decryption for every ciphertext output by the mix. Anyone can verify these proofs.
8. The election officer decrypts each ciphertext and publishes the election result. Anyone can check these decryptions.

See Lee *et al.* [55] for further details.

### 6.2.3 Attacking ballot secrecy

We show that the voting protocol by Lee *et al.* [55] does not satisfy ballot secrecy by recalling the replay attack by Dreier, Lafourcade & Lakhnech [36] that exploits malleability to reveal a voter’s vote. Intuitively, an adversary may identify a voter’s encrypted vote on the bulletin board, since it is signed by the voter. This ciphertext can be submitted to a tamper-resistant hardware device (possibly after re-encryption) and the device will return  $(\hat{a}, \hat{b}), \hat{\sigma}, \hat{\tau}$ ; the ballot  $(\hat{a}, \hat{b}), \hat{\sigma}, \hat{\sigma}'$  can then be submitted by the adversary to the bulletin board, where  $\hat{\sigma}'$  is a signature on  $\hat{\sigma}$  constructed by a registered voter under the adversary’s control. As explained in Section 6.1.2, the multiple occurrences of the voter’s ballot will leak information in the tally and the adversary can exploit this knowledge to violate the voter’s privacy.

**Variant exploiting homomorphic encryption.** The adversary can exploit the homomorphic properties of ElGamal to avoid casting the *same* vote as an honest voter. In this variant, suppose the adversary wants to recover the vote from ballot  $(a'_k, b'_k), \sigma_k, \sigma'_k$ , the adversary derives the ciphertext  $(c, d) = (a'_k, b'_k) \cdot (c', d')$ , where  $(c', d')$  is an ElGamal ciphertext containing some message  $m$ . The adversary submits the ciphertext  $(c, d)$  to a tamper-resistant hardware device and the device will return  $(\hat{c}, \hat{d}), \hat{\sigma}, \hat{\tau}$ ; the ballot  $(\hat{c}, \hat{d}), \hat{\sigma}, \hat{\sigma}'$  can be submitted by the adversary to the bulletin board, where  $\hat{\sigma}'$  is a signature on  $\hat{\sigma}$  constructed by a registered voter. The output of the mix will include the adversaries re-encrypted ciphertext and the election officer will publish  $m \cdot v$  on the bulletin board, where ciphertext  $(a'_k, b'_k)$  includes the vote  $v$ . This variant of the attack is particularly interesting because the replayed ballots are undetectable; in particular, weeding duplicate ballots would clearly not be sufficient to ensure privacy.

### 6.2.4 Privacy in the variant by Küsters & Truderung

Independently, the scheme by Lee *et al.* is vulnerable to a forced abstention attack [51, §6.2], whereby the voter votes for a candidate not included on the candidate list. This can be trivially witnessed since casting a vote for some random nonce will result in a unique occurrence of that nonce being published on the bulletin board by the election officer. Accordingly, Küsters & Truderung [51, §6.3] propose a variant of the protocol by Lee *et al.* which they claim satisfies coercion resistance. In the revised scheme the voter must prove to her tamper-resistant hardware device that her ciphertext contains a valid vote. However, our attack is still valid under one of the following assumptions: 1) there exists a tamper-resistant hardware device which does not check the proof that the voter’s ciphertext is correctly formed; 2) there exists a signing key which has been extracted from a hardware device; or 3) the election officer publishes the public part of a signing key where the private part is known to the adversary. The attack follows immediately from our original description under assumption

---

**Figure 5** Helios administrator that preserves independence but not privacy

---

Given the number of voters  $n \geq 2$  the administration process  $\bar{A}_n^{\phi^{\text{sol}}}$  is defined below, where process  $T$  is presented in Figure 4.

$$\begin{aligned} \bar{A}_n^{\phi^{\text{sol}}} &= \nu \text{sk}_T, a_1, a_2, d . (- \mid \bar{B}B_n^{\phi^{\text{sol}}} \mid !T \mid \{\text{pk}(\text{sk}_T)/z_{\text{pk}}\}) \\ \bar{B}B_n^{\phi^{\text{sol}}} &= a_1(y_1) . \bar{c}\langle y_1 \rangle . a_2(y_2) . \bar{c}\langle y_2 \rangle . \\ &\quad a_3(y_3) . \text{if } \phi^{\text{sol}}\{y_3/y_{\text{ballot}}\} \text{ then} \\ &\quad \dots a_n(y_n) . \text{if } \phi^{\text{sol}}\{y_n/y_{\text{ballot}}\} \text{ then} \\ &\quad \bar{d}\langle (\pi_1(y_1), \pi_2(y_1)) \rangle . d\langle z_1 \rangle . \bar{c}\langle z_1 \rangle . \\ &\quad \dots . \bar{d}\langle (\pi_1(y_n), \pi_2(y_n)) \rangle . d\langle z_n \rangle . \bar{c}\langle z_n \rangle \end{aligned}$$

---

1 and, under assumptions 2 or 3, the adversary signs the encrypted ciphertext without using the tamper-resistant hardware device.

### 6.3 Independence and privacy are unrelated properties

Intuitively, these attacks may be suggestive of a general relationship between independence and privacy properties, however, we shall now present examples that suggest independence does not imply privacy and vice-versa.

**A protocol with independence but no privacy.** Consider a variant of the fixed Helios voting scheme in which each of the trustees publish a partial decryption of individual ciphertexts (rather than a partial decryption of the homomorphically combined ciphertexts, that is, the encrypted tally). Intuitively, this variant preserves ballot independence but does not satisfy ballot secrecy, since the partial decryptions allow votes to be recovered from ballots and the link between a voter and her ballot is known. Formally, this variant is captured by modelling the Helios administrator process as  $\bar{A}_n^{\phi^{\text{sol}}}$ , defined in Figure 5. The violation of ballot secrecy can be witnessed since

$$\bar{A}_2^{\phi^{\text{sol}}} [V\{a_1/x_{\text{auth}}\}\sigma \mid V\{a_2/x_{\text{auth}}\}\tau] \not\approx_l \bar{A}_2^{\phi^{\text{sol}}} [V\{a_1/x_{\text{auth}}\}\tau \mid V\{a_2/x_{\text{auth}}\}\sigma]$$

where  $\sigma = \{\text{zero}/x_1^{\text{vote}}, \text{one}/x_2^{\text{vote}}\}$  and  $\tau = \{\text{one}/x_1^{\text{vote}}, \text{zero}/x_2^{\text{vote}}\}$ . Similarly, a further variant of the fixed Helios scheme in which each of the trustees publishes their private key at the end of the voting phase, rather than a partial decryption of the encrypted tally, also satisfies independence but not ballot secrecy.

**A protocol with privacy but no independence.** Consider a voting scheme in which each voter broadcasts their vote on an anonymous communication channel. Formally, the voter is modelled by the process  $P = \bar{c}\langle x_{\text{vote}} \rangle$ , where variable  $x_{\text{vote}}$  is parametrised by the voter's vote. For ballot secrecy it is sufficient to show  $P\{M/x_{\text{vote}}\} \mid P\{N/x_{\text{vote}}\} \approx_l P\{N/x_{\text{vote}}\} \mid P\{M/x_{\text{vote}}\}$  for all ground

terms  $M$  and  $N$ ; this result trivially holds by structural equivalence and hence the scheme satisfies ballot secrecy. However, independence is intuitively violated in this setting, because an adversary may observe the voting system and replay a previously cast vote, that is, an adversary can cast the same vote as another voter (without knowing which voter). In addition, it follows that early results are available in this scheme.

We also expect some published electronic voting schemes based upon blind signatures to satisfy ballot secrecy but not independence; in particular, a more realistic example of a protocol that satisfies this property is the protocol by Fujioka, Okamoto & Ohta [42] under the assumption that duplicates are not rejected. Indeed, independence can be violated by a verbatim replay of the signed committed vote.

We believe the existence of a weaker property: *privacy and authenticated ballots implies independence*, where the term *authenticated ballot* means the link between an arbitrary ballot and associated voter is known. Informally, this can be witnessed as follows: suppose a system satisfies privacy and authenticated ballots but not independence, it follows that an adversary can identify a voter's ballot and, since there is no independence, replay that ballot; privacy is then violated, as we have shown in this article, hence deriving a contradiction.

In this article, we cannot make any definitive mathematical statements about the relationship between independence and privacy properties, because independence has not been formally defined; however, we hope these examples provide some insight into the relationships we expect.

## 7 Conclusion and further discussion

This article identifies a vulnerability in the Helios 2.0 electronic voting protocol which can be used to violate ballot secrecy. Critics may argue that an attack is unrealistic due its high cost; indeed, in some cases, the attack may change the outcome of an election (that is, the votes introduced for the purposes of violating privacy may swing the result), and large scale privacy invasions would be expensive in terms of the required number of dishonest voters. However, if the views of these critics are to be entertained, then we must revise the standard definitions of ballot secrecy in the literature (for example, [49, 30, 9]) because Helios cannot satisfy them. Furthermore, we believe all voters should be considered equally and, hence, the preservation of ballot secrecy should be universal. But, for elections using Helios, our case study demonstrates the contrary: in French legislative elections a coalition of voters can gain some information about a voter's vote in an arbitrary polling station and, moreover, if the number of voters registered at a particular polling station is small (for example, in a rural setting), then a voter's privacy can be violated by a few dishonest voters. It follows that privacy of individual voters can be compromised by a few dishonest voters and, accordingly, we believe our attack is significant. To address the problem, we have introduced a variant of the Helios protocol which has been shown

to satisfy definitions of ballot secrecy in the applied pi calculus and in our complementary work [15] we present a security proof in the cryptographic setting. The vulnerability in Helios has been acknowledged by Adida & Pereira [6, 8] and they have scheduled a fix for future Helios releases. We have also shown that the absence of ballot independence can be similarly exploited in other electronic voting protocols to violate privacy; in particular, we demonstrate verbatim replay attacks against the schemes by Sako & Kilian [70] and Schoenmakers [72], and we show that the malleable cryptographic scheme adopted by Lee *et al.* [55] can be exploited to replay a voter’s ballot or a variant of it, thereby violating ballot secrecy. In addition, we argue that independence does not imply privacy and vice-versa. Finally, all of the vulnerabilities in this article have been acknowledged by the protocol authors, with the exception of Schoenmakers; in particular, Adida & Pereira have acknowledged the vulnerability in Helios [6, 8] and they have scheduled a fix for future Helios releases.

## Acknowledgements

We are grateful to Ben Adida and Olivier Pereira for their constructive comments, and hope this research will enhance future Helios releases. Discussion with Mark D. Ryan helped clarify the presentation of this article and Ben Adida informed us that Douglas Wikström is the contemporaneous discoverer of the Helios attack. David Bernhard gave useful feedback on the variants of our attack against Helios and Christian Cachin highlighted Josh Benaloh’s related work. The research leading to these results was performed as part of the ProSecure project which is funded by the European Research Council under the European Unions Seventh Framework Programme (FP7/2007-2013) / ERC grant agreement  $n^\circ$  258865, and the ANR-07-SeSur-002 AVOTÉ project.

## A Signatures of knowledge

Helios is reliant on signatures of knowledge to ensure secrecy and integrity of the ElGamal scheme, and to ensure voters encrypt valid votes. This appendix presents suitable cryptographic primitives. Let  $\mathcal{H}$  denote a hash function. In Helios,  $\mathcal{H}$  is defined to be SHA-256.

### A.1 Knowledge of discrete logs

Given the aforementioned cryptographic parameters  $(p, q, g)$ , a signature of knowledge demonstrating knowledge of a discrete logarithm  $h = \log_g g^x$  can be derived, and verified, as defined by [18, 17, 71].

**Sign.** Given  $x$ , select a random nonce  $w \in_R \mathbb{Z}_q^*$ . Compute witness  $g' = g^w \bmod p$ , challenge  $c = \mathcal{H}(g') \bmod q$  and response  $s = w + c \cdot x \bmod q$ .

**Verify.** Given  $h$  and signature  $g', s$ , check  $g^s \equiv g' \cdot h^c \pmod{p}$ , where  $c = \mathcal{H}(g') \bmod q$ .

A valid proof asserts knowledge of  $x$  such that  $x = \log_g h$ ; that is,  $h \equiv g^x \pmod{p}$ .

## A.2 Equality between discrete logs

Given the aforementioned cryptographic parameters  $(p, q, g)$ , a signature of knowledge demonstrating equality between discrete logarithms  $\log_f f^x$  and  $\log_g g^x$  can be derived, and verified, as defined by [63, 19].

**Sign.** Given  $f, g, x$ , select a random nonce  $w \in_R \mathbb{Z}_q^*$ . Compute witnesses  $f^w = f^w \bmod p$  and  $g^w = g^w \bmod p$ , challenge  $c = \mathcal{H}(f', g') \bmod q$  and response  $s = w + c \cdot x \bmod q$ .

**Verify.** Given  $f, g, h, k$  and signature  $f', g', s$ , check  $f^s \equiv f' \cdot h^c \pmod{p}$  and  $g^s \equiv g' \cdot k^c \pmod{p}$ , where  $c = \mathcal{H}(f', g') \bmod q$ .

A valid proof asserts  $\log_f h = \log_g k$ ; that is, there exists  $x$ , such that  $h \equiv f^x \bmod p$  and  $k \equiv g^x \bmod p$ . This signature of knowledge scheme can be extended to a disjunctive proof of equality between discrete logs (see below).

For our purposes, given a ciphertext  $(a, b)$ , each trustee would derive a signature on  $g, a, x_i$ , where  $x_i$  is the trustee's private key share. The  $i$ th trustee's signature  $g'_i, a'_i, c_i, s_i$  would be verified with respect to  $g, a, h_i, k_i$ , where  $h_i$  is the trustee's share of the public key and  $k_i$  is the trustee's partial decryption; that is, the proof asserts  $\log_g h_i = \log_a k_i$ , as required for integrity of decryption.

## A.3 Disjunctive proof of equality between discrete logs

Given the aforementioned cryptographic parameters  $(p, q, g)$ , a signature of knowledge demonstrating that a ciphertext  $(a, b)$  contains either 0 or 1 (without revealing which), can be constructed by proving that either  $\log_g a = \log_h b$  or  $\log_g a = \log_h b/g^m$ ; that is, a signature of knowledge demonstrating a disjunct proof of equality between discrete logarithms [27, 73]. Observe for a valid ciphertext  $(a, b)$  that  $a \equiv g^r \bmod p$  and  $b \equiv h^r \cdot g^m \bmod p$  for some nonce  $r \in \mathbb{Z}_q^*$ ; hence the former disjunct  $\log_g g^r = \log_h h^r \cdot g^m$  is satisfied when  $m = 0$ , and the latter  $\log_g g^r = \log_h (h^r \cdot g^m)/g^m$  when  $m = 1$ .

This technique is generalised by [7] to allow a signature of knowledge demonstrating that a ciphertext  $(a, b)$  contains message  $m$ , where  $m \in \{\min, \dots, \max\}$  for some system parameters  $\min, \max \in \mathbb{N}$ . Formally, a signature of knowledge demonstrating a disjunct proof of equality between discrete logarithms can be derived, and verified, as follows [7, 27, 73].

**Sign.** Given ciphertext  $(a, b)$  such that  $a \equiv g^r \bmod p$  and  $b \equiv h^r \cdot g^m \bmod p$  for some nonce  $r \in \mathbb{Z}_q^*$ , where plaintext  $m \in \{\min, \dots, \max\}$ . For all  $i \in \{\min, \dots, m-1, m+1, \dots, \max\}$ , compute challenge  $c_i \in_R \mathbb{Z}_q^*$ , response  $s_i \in_R \mathbb{Z}_q^*$  and witnesses  $a_i = g^{s_i}/a^{c_i} \bmod p$  and  $b_i = h^{s_i}/(b/g^i)^{c_i} \bmod p$ . Select a random

nonce  $w \in_R \mathbb{Z}_q^*$ . Compute witnesses  $a_m = g^w \bmod p$  and  $b_m = h^w \bmod p$ , challenge  $c_m = \mathcal{H}(a_{\min}, b_{\min}, \dots, a_{\max}, b_{\max}) - \sum_{i \in \{\min, \dots, m-1, m+1, \dots, \max\}} c_i \pmod{q}$  and response  $s_m = w + r \cdot c_m \bmod q$ .

**Verify.** Given  $(a, b)$  and  $(a_{\min}, b_{\min}, c_{\min}, s_{\min}, \dots, a_{\max}, b_{\max}, c_{\max}, s_{\max})$ , for each  $\min \leq i \leq \max$  check  $g^{s_i} \equiv a_i \cdot a^{c_i} \pmod{p}$  and  $h^{s_i} \equiv b_i \cdot (b/g^i)^{c_i} \pmod{p}$ . Finally, check  $\mathcal{H}(a_{\min}, b_{\min}, \dots, a_{\max}, b_{\max}) \equiv \sum_{\min \leq i \leq \max} c_i \pmod{q}$ .

A valid proof asserts that  $(a, b)$  is a ciphertext containing the message  $m$  such that  $m \in \{\min, \dots, \max\}$ .

## B Proof of Theorem 1

### B.1 Preliminaries

Before commencing our proof, let us first introduce some useful lemmas for the applied pi calculus.

**Lemma 3.** *Given frames  $\varphi, \psi$ , ground term  $M$  and variable  $x \notin \text{dom}(\varphi) \cup \text{dom}(\psi)$ , we have  $\varphi \approx_s \psi$  iff  $\varphi \mid \{M/x\} \approx_s \psi \mid \{M/x\}$ .*

**Lemma 4.** *Given frames  $\varphi, \psi$ , terms  $M, N$ , and a variable  $x \notin \text{dom}(\varphi) \cup \text{dom}(\psi)$ , such that  $\varphi = \nu \tilde{m}.\sigma$  and  $\psi = \nu \tilde{n}.\tau$  for some names  $\tilde{m}, \tilde{n}$  and substitutions  $\sigma, \tau$ , we have  $\nu \tilde{m}.\sigma \mid \{M/x\} \approx_s \nu \tilde{n}.\tau \mid \{N/x\}$  implies  $\varphi \approx_s \psi$ .*

The proofs of these lemmas are straightforward.

The following lemma shows when static equivalence implies the same branching behaviour for conditionals.

**Lemma 5.** *Given extended processes  $A \equiv C[\text{if } M = N \text{ then } P \text{ else } Q]$  and  $B \equiv C'[\text{if } M = N \text{ then } P' \text{ else } Q']$  such that  $A \approx_s B$ ,  $(\text{bn}(C) \cup \text{bn}(C')) \cap (\text{fn}(M) \cup \text{fn}(N)) = \emptyset$ ,  $\text{fv}(M) \cup \text{fv}(N) \subseteq \text{dom}(C)$  and  $\text{fv}(M) \cup \text{fv}(N) \subseteq \text{dom}(C')$ , for some closing evaluation context  $C, C'$ , terms  $M, N$  and processes  $P, P', Q, Q'$ , then  $A \rightarrow C[P]$  iff  $B \rightarrow C'[P']$  and  $A \rightarrow C[Q]$  iff  $B \rightarrow C'[Q']$ .*

*Proof.* Suppose  $A \equiv C[\text{if } M = N \text{ then } P \text{ else } Q]$  and  $B \equiv C'[\text{if } M = N \text{ then } P' \text{ else } Q']$  such that  $A \approx_s B$ ,  $(\text{bn}(C) \cup \text{bn}(C')) \cap (\text{fn}(M) \cup \text{fn}(N)) = \emptyset$ ,  $\text{fv}(M) \cup \text{fv}(N) \subseteq \text{dom}(C)$  and  $\text{fv}(M) \cup \text{fv}(N) \subseteq \text{dom}(C')$ , for some closing evaluation context  $C, C'$ , terms  $M, N$  and processes  $P, P', Q, Q'$ . Further suppose  $\varphi(C[\text{if } M = N \text{ then } P \text{ else } Q]) = \nu \tilde{m}.\sigma$  and  $\varphi(C'[\text{if } M = N \text{ then } P' \text{ else } Q']) = \nu \tilde{n}.\tau$ , for some names  $\tilde{m}$  and  $\tilde{n}$ . By Lemma 6 we have  $\nu \tilde{m}.\sigma \approx_s \nu \tilde{n}.\tau$ , because static equivalence is closed under structural equivalence. Moreover, by the definition of static equivalence, for all terms  $U, V$  such that  $(\tilde{m} \cup \tilde{n}) \cap (\text{fn}(U) \cup \text{fn}(V)) = \emptyset$ , we have  $U\sigma =_E V\sigma$  iff  $U\tau =_E V\tau$ .

Let us first show  $A \rightarrow C[P]$  iff  $B \rightarrow C'[P']$ . For the  $\Rightarrow$  implication, suppose  $A \rightarrow C[P]$ . Since  $\text{fv}(M) \cup \text{fv}(N) \subseteq \text{dom}(C)$ , it must be the case that  $M\sigma =_E N\sigma$ . We have  $\tilde{m} \cup \tilde{n} \subseteq \text{bn}(C) \cup \text{bn}(C')$  by definition of the function  $\varphi$ , and we derive  $(\tilde{m} \cup \tilde{n}) \cap (\text{fn}(M) \cup \text{fn}(N)) = \emptyset$  because  $(\text{bn}(C) \cup \text{bn}(C')) \cap (\text{fn}(M) \cup \text{fn}(N)) = \emptyset$ ; it

follows that  $M\sigma =_E N\sigma$  is a special case of  $U\sigma =_E V\sigma$ . We derive  $M\tau =_E N\tau$  from the implication  $(U\sigma =_E V\sigma) \Rightarrow (U\tau =_E V\tau)$ . It trivially follows that  $B \equiv C'[\text{if } M\tau = N\tau \text{ then } P' \text{ else } Q']$ , and by closure of internal reduction under structural equivalence we derive  $B \rightarrow C'[P']$ . The  $\Leftarrow$  implications follows by symmetry.

We will now show  $A \rightarrow C[Q]$  iff  $B \rightarrow C'[Q']$ . For the  $\Rightarrow$  implication, suppose  $A \rightarrow C[Q]$ . It must be the case that  $M\sigma \neq_E N\sigma$  and, as before, we derive  $M\tau \neq_E N\tau$ . It trivially follows that  $B \equiv C'[\text{if } M\tau = N\tau \text{ then } P' \text{ else } Q']$ , and since  $\text{fv}(M) \cup \text{fv}(N) \subseteq \text{dom}(C')$  we are assured that terms  $M\tau, N\tau$  are ground; by closure of internal reduction under structural equivalence we derive  $B \rightarrow C'[Q']$ . The  $\Leftarrow$  implications follows by symmetry.  $\square$

This result can naturally be extended to formula. Given  $\phi$ , let us denote the set of free names, respectively variables, in  $\phi$  as  $\text{fn}(\phi)$ , respectively  $\text{fv}(\phi)$ .

**Corollary 1.** *Given extended processes  $A \equiv C[\text{if } \phi \text{ then } P \text{ else } Q]$  and  $B \equiv C'[\text{if } \phi \text{ then } P' \text{ else } Q']$  such that  $A \approx_s B$ ,  $(\text{bn}(C) \cup \text{bn}(C')) \cap \text{fn}(\phi) = \emptyset$ ,  $\text{fv}(\phi) \subseteq \text{dom}(C)$  and  $\text{fv}(\phi) \subseteq \text{dom}(C')$ , for some closing evaluation context  $C, C'$ , formulae  $\phi$  and processes  $P, P', Q, Q'$ , then  $A \rightarrow C[P]$  iff  $B \rightarrow C'[P']$  and  $A \rightarrow C[Q]$  iff  $B \rightarrow C'[Q']$ .*

We conclude this subsection with a useful result stated by Abadi & Fournet [1].

**Lemma 6.** *Static equivalence is closed by structural equivalence.*

## B.2 Notations and Definitions

For the remainder of this article, let  $\ell$  be some number of candidates,  $n \geq 2$  be some number of voters, and  $\sigma$  and  $\sigma'$  be candidate substitutions.

### B.2.1 Notations

We introduce the following notations for all  $1 \leq i \leq n$  and  $1 \leq j \leq \ell$ :

$$\begin{aligned}
\text{tally}_j &= \pi_j(y_1) * \dots * \pi_j(y_n) \\
\text{partial}_j &= \text{partial}(sk_T, \text{tally}_j) \\
\text{result}_j &= \text{dec}(\text{partial}_j, \text{tally}_j) \\
\text{ciph}_{i,j} &= \text{penc}(z_{\text{pk}}, r_{i,j}, x_{i,j}^{\text{vote}}) \\
\text{spk}_{i,j} &= \text{spk}(z_{\text{pk}}, r_{i,j}, x_{i,j}^{\text{vote}}, \text{ciph}_{i,j}) \\
\widehat{\text{spk}}_i &= \text{spk}(z_{\text{pk}}, r_{i,1} \circ \dots \circ r_{i,\ell}, x_{i,1}^{\text{vote}} + \dots + x_{i,\ell}^{\text{vote}}, \text{ciph}_{i,1} * \dots * \text{ciph}_{i,\ell}) \\
\text{ballot}_i &= (\text{ciph}_{i,1}, \dots, \text{ciph}'_{i,\ell}, \text{spk}_{i,1}, \dots, \text{spk}'_{1,\ell}, \widehat{\text{spk}}_i) \\
\tau_L &= \{M/x_{1,i}^{\text{vote}} \mid \text{for all } 1 \leq i \leq \ell \text{ such that } \{M/x_i^{\text{vote}}\} \in \sigma\} \\
&\quad \cup \{N/x_{2,i}^{\text{vote}} \mid \text{for all } 1 \leq i \leq \ell \text{ such that } \{N/x_i^{\text{vote}}\} \in \sigma'\} \\
\tau_R &= \{N/x_{1,i}^{\text{vote}} \mid \text{for all } 1 \leq i \leq \ell \text{ such that } \{N/x_i^{\text{vote}}\} \in \sigma'\} \\
&\quad \cup \{M/x_{2,i}^{\text{vote}} \mid \text{for all } 1 \leq i \leq \ell \text{ such that } \{M/x_i^{\text{vote}}\} \in \sigma\}
\end{aligned}$$

## B.2.2 Definitions

Given  $N_3, \dots, N_k$  terms such that  $\text{fv}(N_j) \subseteq \{z_{\text{pk}}, y_1, \dots, y_{j-1}\}$ , we define

$$\sigma_{\bar{N}_k} = \{\text{ballot}_1/y_1, \text{ballot}_2/y_2, N_j/y_j \mid j \in \{3, \dots, k\}\}$$

Given an integer  $k \in \mathbb{N}^+$  and a term  $N$ , we define  $N^k$  (resp.  $k.N$ ) to be  $N \circ \dots \circ N$  (resp.  $N + \dots + N$ ) where  $N$  is replicated  $k$  times.

We associate to the equational theory  $E$  a rewriting system  $\mathcal{R}_E$  by orienting the Equations E1, E2 and E5 to E9 from left to right. We denote by  $E'$  the equational theory that asserts functions  $+$ ,  $*$ ,  $\circ$  are commutative and associative in addition to Equations E3 and E4.  $\mathcal{R}_E$  modulo  $E'$  forms a convergent rewriting system (modulo  $E'$ ). We denote by  $u \rightarrow_E v$  (or often simply  $u \rightarrow v$ ) if  $u$  modulo  $E'$  can be rewritten to  $v$  modulo  $E'$ , using  $\mathcal{R}_E$ . We denote by  $u \downarrow$  a normal form of  $u$  modulo  $E'$ .

We will say that a term  $M$  is *free* w.r.t. a set of names  $\bar{n}$  if it does not contain any name of  $\bar{n}$ . We simply say that a term is free when the set of names is clear from the context (typically free w.r.t. to the restricted names of a frame).

## B.3 Some useful lemmas

We prove some useful results about our definitions and notations. We first show that ballots accepted by the bulletin board must have a particular form due to the checks performed by  $\phi_{\ell, \bar{n}}^{\text{sol}}$ .

**Lemma 7.** *Let  $\ell$  be a number of candidates,  $\bar{n} \geq 2$  be an integer, and  $M$  be term free w.r.t.  $r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}$  and such that  $\text{fv}(M) \subseteq \{z_{\text{pk}}, y_1, y_2\}$ . Let substitution  $\tau \in \{\tau_L, \tau_R\}$  and substitution  $\sigma = \{\text{pk}(sk_T)/z_{\text{pk}}, \text{ballot}_1/y_1, \text{ballot}_2/y_2\}$ . If  $\llbracket \phi_{\ell, \bar{n}}^{\text{sol}} \{M/y_{\text{ballot}}\} \sigma \tau \rrbracket = \text{true}$ , then there exists a term*

$$M' = (\text{penc}(z_{\text{pk}}, N_1, M_1), \dots, \text{penc}(z_{\text{pk}}, N_\ell, M_\ell), S_1, \dots, S_{\ell+1})$$

for some terms  $M_1, \dots, M_\ell, N_1, \dots, N_\ell, S_1, \dots, S_{\ell+1}$  such that  $M \sigma \tau =_E M' \sigma \tau$ ,  $M'$  is free w.r.t.  $r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}$ ,  $\text{fv}(M') \subseteq \{z_{\text{pk}}, y_1, y_2\}$ , and  $\{M_1/x_1^{\text{vote}}, \dots, M_\ell/x_\ell^{\text{vote}}\}$  is a candidate substitution.

*Proof.* Let  $M$ ,  $\tau$  and  $\sigma$  be defined as in the Lemma, and suppose  $\llbracket \phi_{\ell, \bar{n}}^{\text{sol}} \{M/y_{\text{ballot}}\} \sigma \tau \rrbracket = \text{true}$ . We say that a term  $N$  is a *minimal recipe* if it is minimal (in size) among the terms  $N'$  such that  $N \sigma \tau =_E N' \sigma \tau$ . It is easy to check by induction on the size of  $N$  that, whenever  $N = f(N_1, \dots, N_k)$  with  $f \in \{\text{dec}, \pi_j \mid 1 \leq j \leq \ell\}$  then either  $N = \pi_j(x)$  for some  $j$  and variable  $x$  or  $(N \sigma \tau) \downarrow = f((N_1 \sigma \tau) \downarrow, \dots, (N_k \sigma \tau) \downarrow)$  (\*).

W.l.o.g. suppose  $M'$  is a minimal recipe such that  $M \sigma \tau =_E M' \sigma \tau$  and  $M'$  is free w.r.t.  $r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}$ . Further suppose w.l.o.g. that  $M'$  is in normal form. We know  $\llbracket \phi_{\ell, \bar{n}}^{\text{sol}} \{M'/y_{\text{ballot}}\} \sigma \tau \rrbracket = \text{true}$ . Thus it must be the case that  $M' \sigma \tau$  is of the form  $(U_1, \dots, U_\ell, V_1, \dots, V_\ell, W)$ , where for  $1 \leq j \leq \ell$  we have  $U_j = \text{penc}(\text{pk}(sk_T), R_j, C_j)$ ,  $C_j \in \{\text{zero}, \text{one}\}$  and  $\{C_1/x_1^{\text{vote}}, \dots, C_\ell/x_\ell^{\text{vote}}\}$  is

a candidate substitution. Due to the disequality tests in  $\phi_{\ell, \tilde{n}}^{\text{sol}}$ , it must be the case that  $M'$  is of the form  $(T_1, \dots, T_\ell, S_1, \dots, S_\ell, Z)$  and  $T_j \notin \{\pi_k(y_i) \mid 1 \leq k \leq \ell\}$ . We have  $T_j \sigma \tau = \text{penc}(A_j, B_j, C_j)$ . Assume first that  $T_j = \pi_k(T'_j)$ . Due to (\*), we must have  $T'_j$  variable, which is excluded by the fact that  $T_j \notin \{\pi_k(y_i) \mid 1 \leq k \leq \ell\}$ . Thus, due to the equational theory and (\*), it must be the case that  $T_j = \text{penc}(K_j, N_j, M_j) * \prod_{1 \leq k \leq \ell} \pi_k(y_1)^{\alpha_k} * \pi_k(y_2)^{\beta_k}$  where each component is optional and  $\alpha_i \in \mathbb{N}$ . By convention  $\alpha_i = 0$  or  $\beta_i = 0$  means that the component is skipped. Assume that one of the  $\alpha_i$  or  $\beta_i$  is not null. Then  $R_j = r \circ R'_j$  with  $r \in \{r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}\}$ . Due to the tests in  $\phi_{\ell, \tilde{n}}^{\text{sol}}$ , we know  $V_j = \text{spk}(\text{pk}(sk_T), R_j, C_j, V'_j)$ .

Let us show that  $V_j$  cannot be a signature of knowledge that appears in either  $\text{ballot}_{1\tau_L}$  or  $\text{ballot}_{2\tau_L}$ . Assume (by contradiction) that  $V_j$  is a signature of knowledge that appears in either  $\text{ballot}_{1\tau_L}$  or  $\text{ballot}_{2\tau_L}$ . Due to weeding, we cannot have  $V_j = \text{spk}_{i,k}$ . Indeed, due to the equational theory, this would imply that  $U_j$  is equal to a previously received cyphertext, which is excluded by weeding. Thus we must have  $V_j = \widehat{\text{spk}}_i$  for some  $i \in \{1, 2\}$ . Then  $R_j = r_{i,1} \circ \dots \circ r_{i,\ell}$ . In that case, let us have a look at  $W$ . We know  $W = \text{spk}(\text{pk}(sk_T), R_1 \circ \dots \circ R_\ell, C_1 + \dots + C_\ell, U_1 * \dots * U_\ell)$ . Thus  $W$  cannot be one of the signatures of knowledge that appear in  $\text{ballot}_{1\tau_L}$  or  $\text{ballot}_{2\tau_L}$  (the depth of  $R_1 \circ \dots \circ R_\ell$  is too big). Therefore (and due to the equational theory and minimality of  $Z$ ), we must have  $Z = \text{spk}(Z^1, Z^2, Z^3, Z^4)$ . Since  $r_{i,1} \circ \dots \circ r_{i,\ell}$  is not deducible, we cannot have  $Z^2 \sigma \tau =_E r_{i,1} \circ \dots \circ r_{i,\ell} \circ R_1 \circ R_{j-1} \circ R_{j+1} \circ R_\ell$ , contradiction.

We must have  $S_j = \text{spk}(S_j^1, S_j^2, S_j^3, S_j^4)$ , since  $V_j$  cannot be one of the signatures of proof of knowledge that appear in  $\text{ballot}_{1\tau_L}$  or  $\text{ballot}_{2\tau_L}$ , and due to the equational theory. Since  $r$  is not deducible, we cannot have  $S_j^2 \sigma \tau =_E r \circ R'_j$ , contradiction. We therefore deduce that  $T_j = \text{penc}(K_j, N_j, M_j)$ . Moreover,  $K_j \sigma \tau =_E \text{pk}(sk_T)$  implies  $K_j = z_{\text{pk}}$  and  $M_j \sigma \tau =_E \text{zero}$  or  $\text{one}$  implies  $M_j \in \{\text{zero}, \text{one}\}$  due to the equational theory. Due to the validity check, we also deduce that  $\{M_1/x_1^{\text{vote}}, \dots, M_\ell/x_\ell^{\text{vote}}\}$  is a candidate substitution.  $\square$

**Lemma 8.** *Let  $\phi_1 = \nu sk_T, d, r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell} \cdot (\{\text{ballot}_1/x_1\} \mid \{\text{ballot}_2/x_2\} \mid \{\text{pk}(sk_T)/z_{\text{pk}}\})$ . We have  $\phi_1 \tau_L \approx_s \phi_1 \tau_R$ .*

*Proof.* First, we decompose  $\phi_1$  and consider  $\phi = \nu \tilde{n} \cdot \theta$ , where  $\tilde{n} = \{sk_T, d, r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}\}$  and  $\theta = \{\text{pk}(sk_T)/z_{\text{pk}}\} \mid \left\{ \left\{ \text{ciph}_{i,j}/x_{\text{ciph}_{i,j}} \right\} \mid \left\{ \widehat{\text{spk}}_{i,j}/x_{\text{spk}_{i,j}} \right\} \mid \left\{ \widehat{\text{spk}}_i/x_{\widehat{\text{spk}}_i} \right\} \mid i \in \{1, 2\} \wedge 1 \leq j \leq \ell \right\}$ . It follows immediately that  $\phi_1 \tau_L \approx_s \phi_1 \tau_R$  if and only if  $\phi \tau_L \approx_s \phi \tau_R$ .

Secondly, witness that the adversary can arbitrarily combine ciphertexts from the frame – namely, ciphertexts  $\text{ciph}_{1,1}, \text{ciph}_{2,1}, \dots, \text{ciph}_{1,\ell}, \text{ciph}_{2,\ell}$  – with ciphertexts in the frame or freshly constructed ciphertexts, we enrich the frame  $\phi$  with any such combination of ciphertexts. Formally, for any  $\alpha_j, \beta_j \in \mathbb{N}$  and terms  $P, R$  we define  $C_{\alpha_1, \dots, \alpha_\ell, \beta_1, \dots, \beta_\ell, \alpha_4, P, R}$  as follows:

$$\text{penc}(\text{pk}(sk_T), R \circ \bigcirc_{1 \leq j \leq \ell} r_{1,j}^{\alpha_j} \circ r_{2,j}^{\beta_j}, P + \sum_{1 \leq j \leq \ell} \alpha_j \cdot x_{1,j}^{\text{vote}} + \beta_j \cdot x_{2,j}^{\text{vote}})$$

We define the extended frame  $\phi_e$  below.

$$\phi_e = \nu \tilde{n}.(\theta \mid \{C_{\alpha_1, \alpha_2, \alpha_3, \alpha_4, P, R} / x_{\alpha_1, \alpha_2, \alpha_3, \alpha_4, P, R} \mid \alpha_1, \alpha_2, \alpha_3, \alpha_4 \in \mathbb{N} \text{ and terms } P, R \text{ s.t. } (\text{fn}(P) \cup \text{fn}(R)) \cap \tilde{n} = \emptyset, \text{fv}(P, R) \subseteq \text{dom}(\phi_e) \text{ with no cycle}\})$$

Note that  $\phi_e$  is infinite. By Lemma 4, it is sufficient to show  $\phi_e \tau_L \approx_s \phi_e \tau_R$ . We introduce the following two claims.

**Claim 1.** *Let  $M$  be a term such that  $\text{fv}(M) \cap (\text{fv}(\phi_e) \setminus \text{dom}(\phi_e)) = \emptyset$  and  $\text{fn}(M) \cap \tilde{n} = \emptyset$ . If  $M \phi_e \tau \rightarrow U$  for some  $\tau \in \{\tau_R, \tau_L\}$ , then there exists  $N$  such that  $U =_{E'} N \phi_e \tau$  and  $M \phi_e \tau' \rightarrow N \phi_e \tau'$  for any  $\tau' \in \{\tau_R, \tau_L\}$ .*

**Claim 2.** *Let  $M, N$  be two terms such that  $(\text{fv}(M) \cup \text{fv}(N)) \cap (\text{fv}(\phi_e) \setminus \text{dom}(\phi_e)) = \emptyset$  and  $\text{fn}(M, N) \cap \tilde{n} = \emptyset$ . If  $M \phi_e \tau =_{E'} N \phi_e \tau$  for some  $\tau \in \{\tau_R, \tau_L\}$ , then  $M \phi_e =_{E'} N \phi_e$ .*

The above claims allow the construction of our proof. Let  $M, N$  be two terms such that  $\text{fn}(M, N) \cap \tilde{n} = \emptyset$  and  $M \phi_e \sigma_{\tilde{N}_k} \tau_L =_E N \phi_e \sigma_{\tilde{N}_k} \tau_L$ . We assume (possibly by renaming) that  $(\text{fv}(M) \cup \text{fv}(N)) \cap (\text{fv}(\phi_e) \setminus \text{dom}(\phi_e)) = \emptyset$ . We have  $M \phi_e \tau_L =_E N \phi_e \tau_L$ . Thus  $(M \phi_e \tau_L) \downarrow =_{E'} (N \phi_e \tau_L) \downarrow$ . Applying repeatedly Claim 1, we deduce that there exists  $M'$  such that  $(M \phi_e \tau_L) \downarrow = M' \phi_e \tau_L$  and  $M \phi_e \tau_R \rightarrow^* M' \phi_e \tau_R$ . Similarly, there exists  $N'$  such that  $(N \phi_e \tau_L) \downarrow = N' \phi_e \tau_L$  and  $N \phi_e \tau_R \rightarrow^* N' \phi_e \tau_R$ . From  $M' \phi_e \tau_L =_{E'} N' \phi_e \tau_L$  and Claim 2, we deduce  $M' \phi_e =_{E'} N' \phi_e$ . Therefore  $M' \phi_e \tau_R =_{E'} N' \phi_e \tau_R$  and thus  $M \phi_e \tau_R =_E N \phi_e \tau_R$ , that is  $M \phi_e \sigma_{\tilde{N}_k} \tau_R =_E N \phi_e \sigma_{\tilde{N}_k} \tau_R$ .

*Proof of Claim 1:* This result is proved by inspection of the rewrite rules, using the fact that the decryption key  $sk_T$  is not deducible. More precisely, assume that  $M \phi_e \tau \rightarrow U$  for some  $\tau \in \{\tau_R, \tau_L\}$ . It means that there exists a rewriting rule  $l \rightarrow r \in \mathcal{R}_E$  and a position  $p$  such that  $M \phi_e \tau|_p =_{E'} l \theta$  for some  $\theta$ .  $p$  cannot occur below  $M$  since  $\phi_e \tau$  is in normal form. If  $M|_p = l \theta'$  for some  $\theta'$  then we conclude that we can rewrite  $M$  as expected. The only interesting case is thus when  $M|_p$  is not an instance of  $l$  but  $M \phi_e \tau|_p$  is. By inspection of the rules,  $l \rightarrow r$  can only correspond to one of the three equations E5, E6 or E7. The case of Equations E5 or E6 is ruled out by the fact that  $sk_T$  is not deducible from  $\phi_e \tau$ . The last case is when the rule corresponding to Equation E7 is applied. Then it must be the case that  $M|_p = x * y$  with  $x, y$  variables of  $\text{dom}(\phi_e)$ . By construction of  $\phi_e$ , we have that  $(x * y) \phi_e \rightarrow z \phi_e$  (applying the rule corresponding to Equation E7), thus the result.

*Proof of Claim 2:* Assume by contradiction that there exist  $M, N$  two terms such that  $M \phi_e \tau =_{E'} N \phi_e \tau$  for some  $\tau \in \{\tau_R, \tau_L\}$  and  $M \phi_e \neq_{E'} N \phi_e$ . Consider  $M, N$  two minimal terms that satisfy this property. By case inspection, it must be the case that  $M$  and  $N$  are both variables. Thus we have  $x \phi_e \tau =_{E'} y \phi_e \tau$  and  $x \phi_e \neq_{E'} y \phi_e$  with  $x, y \in \text{dom}(\phi_e)$ ,  $x \neq y$ . The head symbol of  $x \phi_e \tau$  must be **penc**. Then by construction of  $\phi_e$ ,  $\tau$  does not change the randomness used in **penc** and the randomness uniquely determines the variable, which implies  $x = y$ , contradiction.  $\square$

We now demonstrate that tallying valid ballots yields the same result in both worlds.

**Lemma 9.** *Let  $\ell$ , be a number of candidates. Let  $N_3, \dots, N_k$  be terms, free w.r.t.  $sk_T, d, r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}$ . Let  $\theta_{\tilde{N}_k} = \{N_k/y_k \mid k \in \{3, \dots, n\}\}$  such that  $N_i \theta_{\tilde{N}_k} \sigma \tau$  is a valid ballot for any  $\tau \in \{\tau_L, \tau_R\}$ . Let  $\sigma = \{\text{pk}(sk_T)/z_{\text{pk}}, \text{ballot}_1/y_1, \text{ballot}_2/y_2\}$ . Then*

$$\text{result}_i \theta_{\tilde{N}_k} \sigma \tau_L =_E \text{result}_i \theta_{\tilde{N}_k} \sigma \tau_R$$

and both  $\text{result}_j \theta_{\tilde{N}_k} \sigma \tau_L$  and  $\text{result}_j \theta_{\tilde{N}_k} \sigma \tau_R$  are terms built from constants one and zero by application of the function symbol  $+$ .

*Proof.* We first define  $N'_i = N_i \theta_{\tilde{N}_k}$ . By Lemma 7, we know that  $\pi_j(N'_i \sigma \tau_L) =_E \text{penc}(z_{\text{pk}}, U_j^i, V_j^i) \sigma \tau_L$  for some free terms  $U_j^i, V_j^i$ . By Lemma 8, we know that  $\phi_1 \tau_L \approx_s \phi_1 \tau_R$  thus we can deduce  $\pi_j(N'_i \sigma \tau_R) =_E \text{penc}(z_{\text{pk}}, U_j^i, V_j^i) \sigma \tau_R$ . The equational theory ensure that  $\text{penc}(K, U, V) =_E \text{penc}(K', U', V')$  implies  $K =_E K'$ ,  $U =_E U'$ , and  $V =_E V'$ . Thus we deduce  $V_j^i \sigma \tau_L =_E V_j^i \sigma \tau_R$ . Therefore, we get that  $\text{result}_j \theta_{\tilde{N}_k} \sigma \tau_L =_E x_{1,j}^{\text{vote}} \tau_L + x_{2,j}^{\text{vote}} \tau_L + (V_j^3 + \dots + V_j^k) \sigma \tau_L =_E x_{1,j}^{\text{vote}} \tau_R + x_{2,j}^{\text{vote}} \tau_R + (V_j^3 + \dots + V_j^k) \sigma \tau_R =_E \text{result}_j \theta_{\tilde{N}_k} \sigma \tau_R$ .

Moreover,  $V_j^i \sigma \tau \in \{\text{one}, \text{zero}\}$  is ensured by the fact that  $N_i \theta_{\tilde{N}_k} \sigma \tau$  is a valid ballot. Therefore we deduce that both  $\text{result}_j \theta_{\tilde{N}_k} \sigma \tau_L$  and  $\text{result}_j \theta_{\tilde{N}_k} \sigma \tau_R$  are terms built from constants one and zero by application of the function symbol  $+$ .  $\square$

We finally show that the encrypted ballots of honest voters and the partial decryptions do not leak any information to the adversary.

**Lemma 10.** *Let  $\phi_6 = \nu sk_T, d, r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell} \cdot (\{\text{ballot}_1/x_1\} \mid \{\text{ballot}_2/x_2\} \mid \{\text{pk}(sk_T)/z_{\text{pk}}\} \mid \{\text{partial}_j/x_j^{\text{partial}} \mid 1 \leq j \leq \ell\})$ . We have  $\phi_6 \sigma_{\tilde{N}_k} \tau_L \approx_s \phi_6 \sigma_{\tilde{N}_k} \tau_R$ .*

The proof is very similar to the proof of Lemma 8

*Proof.* First, we decompose  $\phi_6$  and consider  $\phi = \nu \tilde{n} \cdot \theta$  where  $\tilde{n} = \{sk_T, d, r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}\}$  and  $\theta = \{\text{pk}(sk_T)/z_{\text{pk}}\} \mid \left\{ \left\{ \text{partial}_j/x_{\text{partial}_j} \right\} \mid \left\{ \text{ciph}_{i,j}/x_{\text{ciph}_{i,j}} \right\} \mid \left\{ \widehat{\text{spk}}_{i,j}/x_{\widehat{\text{spk}}_{i,j}} \right\} \mid \left\{ \widehat{\text{spk}}_i/x_{\widehat{\text{spk}}_i} \right\} \mid i \in \{1, 2\} \wedge 1 \leq j \leq \ell \right\}$ . It follows immediately that  $\phi_6 \tau_L \approx_s \phi_6 \tau_R$  if and only if  $\phi \tau_L \approx_s \phi \tau_R$ .

Secondly, witness that the adversary can arbitrarily combine ciphertexts from the frame – namely, ciphertexts  $\text{ciph}_{1,1}, \text{ciph}_{2,1}, \dots, \text{ciph}_{1,\ell}, \text{ciph}_{2,\ell}$  – with ciphertexts in the frame or freshly constructed ciphertexts, we enrich the frame  $\phi$  with any such combination of ciphertexts. Formally, for any  $\alpha_j, \beta_j \in \mathbb{N}$  and terms  $P, R$  we define  $C_{\alpha_1, \dots, \alpha_\ell, \beta_1, \dots, \beta_\ell, \alpha_4, P, R}$  as follows:

$$\text{penc}(\text{pk}(sk_T), R \circ \bigcirc_{1 \leq j \leq \ell} r_{1,j}^{\alpha_j} \circ r_{2,j}^{\beta_j}, P + \sum_{1 \leq j \leq \ell} \alpha_j \cdot x_{1,j}^{\text{vote}} + \beta_j \cdot x_{2,j}^{\text{vote}})$$

We define the extended frame  $\phi_e$  below.

$$\phi_e = \nu \tilde{n}.(\theta \mid \{C_{\alpha_1, \alpha_2, \alpha_3, \alpha_4, P, R} / x_{\alpha_1, \alpha_2, \alpha_3, \alpha_4, P, R} \mid \alpha_1, \alpha_2, \alpha_3, \alpha_4 \in \mathbb{N} \text{ and terms } P, R \text{ s.t. } (\text{fn}(P) \cup \text{fn}(R)) \cap \tilde{n} = \emptyset, \text{fv}(P, R) \subseteq \text{dom}(\phi_e) \text{ with no cycle}\})$$

Note that  $\phi_e$  is infinite. By Lemma 4, it is sufficient to show  $\phi_e \tau_L \approx_s \phi_e \tau_R$ . Let  $\phi'_e = \phi_e \sigma_{\tilde{N}_k}$ . We introduce the following two claims.

**Claim 3.** *Let  $M$  be a term such that  $\text{fv}(M) \cap (\text{fv}(\phi'_e) \setminus \text{dom}(\phi'_e)) = \emptyset$  and  $\text{fn}(M) \cap \tilde{n} = \emptyset$ . If  $M \phi'_e \tau \rightarrow U$  for some  $\tau \in \{\tau_R, \tau_L\}$  then there exists  $N$  such that  $U =_{E'} N \phi'_e \tau$  and  $M \phi'_e \tau' \rightarrow N \phi'_e \tau'$  for any  $\tau' \in \{\tau_R, \tau_L\}$ .*

**Claim 4.** *Let  $M, N$  be two terms such that  $(\text{fv}(M) \cup \text{fv}(N)) \cap (\text{fv}(\phi'_e) \setminus \text{dom}(\phi'_e)) = \emptyset$  and  $\text{fn}(M, N) \cap \tilde{n} = \emptyset$ . If  $M \phi'_e \tau =_{E'} N \phi'_e \tau$  for some  $\tau \in \{\tau_R, \tau_L\}$  then  $M \phi'_e =_{E'} N \phi'_e$ .*

The above claims allow the construction of our proof. Let  $M, N$  be two terms such that  $\text{fn}(M, N) \cap \tilde{n} = \emptyset$  and  $M \phi'_e \sigma_{\tilde{N}_k} \tau_L =_E N \phi'_e \sigma_{\tilde{N}_k} \tau_L$ . We assume (possibly by renaming) that  $(\text{fv}(M) \cup \text{fv}(N)) \cap (\text{fv}(\phi'_e) \setminus \text{dom}(\phi'_e)) = \emptyset$ . We have  $M \phi'_e \tau_L =_E N \phi'_e \tau_L$ . Thus  $(M \phi'_e \tau_L) \downarrow =_{E'} (N \phi'_e \tau_L) \downarrow$ . Applying repeatedly Claim 3, we deduce that there exists  $M'$  such that  $(M \phi'_e \tau_L) \downarrow = M' \phi'_e \tau_L$  and  $M \phi'_e \tau_R \rightarrow^* M' \phi'_e \tau_R$ . Similarly, there exists  $N'$  such that  $(N \phi'_e \tau_L) \downarrow = N' \phi'_e \tau_L$  and  $N \phi'_e \tau_R \rightarrow^* N' \phi'_e \tau_R$ . From  $M' \phi'_e \tau_L =_{E'} N' \phi'_e \tau_L$  and Claim 4, we deduce  $M' \phi'_e =_{E'} N' \phi'_e$ . Therefore  $M' \phi'_e \tau_R =_{E'} N' \phi'_e \tau_R$  and thus  $M \phi'_e \tau_R =_E N \phi'_e \tau_R$ , that is  $M \phi'_e \sigma_{\tilde{N}_k} \tau_R =_E N \phi'_e \sigma_{\tilde{N}_k} \tau_R$ .

*Proof of Claim 3:* This result is proved by inspection of the rewrite rules, using the fact that the decryption key  $sk_T$  is not deducible. More precisely, assume that  $M \phi'_e \tau \rightarrow U$  for some  $\tau \in \{\tau_R, \tau_L\}$ . It means that there exists a rewriting rule  $l \rightarrow r \in \mathcal{R}_E$  and a position  $p$  such that  $M \phi'_e \tau|_p =_{E'} l \theta$  for some  $\theta$ .  $p$  cannot occur below  $M$  since  $\phi'_e \tau$  is in normal form. If  $M|_p = l \theta'$  for some  $\theta'$  then we conclude that we can rewrite  $M$  as expected. The only interesting case is thus when  $M|_p$  is not an instance of  $l$  but  $M \phi'_e \tau|_p$  is. By inspection of the rules,  $l \rightarrow r$  can only correspond to one of the three equations E5, E6 or E7. The case of Equations E5 is ruled out by the fact that  $sk_T$  is not deducible from  $\phi'_e \tau$ . For Equation E6, it must be the case that  $M \phi'_e|_p = \text{result}_j \sigma_{\tilde{N}_k}$ . Using Lemma 9, we deduce that  $M \phi'_e|_p \tau \rightarrow R$  modulo  $E'$  where  $R$  is a sum of ones and zero. Therefore  $M \phi'_e \tau \rightarrow M[R]_p \phi'_e \tau$ . The last case is when the rule corresponding to Equation E7 is applied. Then it must be the case that  $M|_p = x * y$  with  $x, y$  variables of  $\text{dom}(\phi'_e)$ . By construction of  $\phi'_e$ , we have that  $(x * y) \phi'_e \rightarrow z \phi'_e$  (applying the rule corresponding to Equation E7), thus the result.

*Proof of Claim 4:* Assume by contradiction that there exist  $M, N$  two terms such that  $M \phi'_e \tau =_{E'} N \phi'_e \tau$  for some  $\tau \in \{\tau_R, \tau_L\}$  and  $M \phi'_e \neq_{E'} N \phi'_e$ . Consider  $M, N$  two minimal terms that satisfy this property. By case inspection, it must be the case that  $M$  and  $N$  are both variables. Thus we have  $x \phi'_e \tau =_{E'} y \phi'_e \tau$  and  $x \phi'_e \neq_{E'} y \phi'_e$  with  $x, y \in \text{dom}(\phi'_e)$ ,  $x \neq y$ . The head symbol of  $x \phi'_e \tau$

---

**Figure 6** Partial evolutions of the Helios process specification

---

We introduce some partial evolutions of the Helios process specification:

$$\begin{aligned}
A^1 &= \nu sk_T, a_2, d, r_{1,1}, \dots, r_{1,\ell}, y_1 \cdot (- \mid \{\text{ballot}_1/y_1\} \mid \{\text{pk}(sk_T)/z_{\text{pk}}\}) \\
A^2 &= A^1[- \mid \{\text{ballot}_1/x_1\}] \\
A^3 &= \nu sk_T, d, r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}, y_1, y_2 \cdot (- \mid \\
&\quad \{\text{ballot}_1/y_1\} \mid \{\text{ballot}_2/y_2\} \mid \{\text{ballot}_1/x_1\} \mid \{\text{pk}(sk_T)/z_{\text{pk}}\}) \\
A^4 &= A^3[- \mid \{\text{ballot}_2/x_2\}] \\
A^5 &= A^4[\nu y_{\text{partial}} \cdot (- \mid \{\text{partials}/y_{\text{partial}}\})] \\
A^6 &= A^5[- \mid \{\text{partials}/x_{\text{partial}}\}] \\
A^7 &= A^6[\{\text{results}/x_{\text{result}}\}] \\
\\
BB_n^1 &= \bar{c}\langle y_1 \rangle \cdot BB_n^2 \\
BB_n^2 &= a_2\langle y_2 \rangle \cdot BB_n^3 \\
BB_n^3 &= \bar{c}\langle y_2 \rangle \cdot BB'_{3,n} \\
BB'_{j,n} &= a_j\langle y_j \rangle \cdot \text{if } \phi_{\ell,j-1}^{\text{sol}}\{y_j/y_{\text{ballot}}\} \text{ then} \\
&\quad \dots a_n\langle y_n \rangle \cdot \text{if } \phi_{\ell,n-1}^{\text{sol}}\{y_n/y_{\text{ballot}}\} \text{ then} \\
&\quad BB_n^4 \\
BB''_{j,n} &= \text{if } \phi_{\ell,j-1}^{\text{sol}}\{y_j/y_{\text{ballot}}\} \text{ then} \\
&\quad a_{j+1}\langle y_{j+1} \rangle \cdot \text{if } \phi_{\ell,j}^{\text{sol}}\{y_{j+1}/y_{\text{ballot}}\} \text{ then} \\
&\quad \dots a_n\langle y_n \rangle \cdot \text{if } \phi_{\ell,n-1}^{\text{sol}}\{y_n/y_{\text{ballot}}\} \text{ then} \\
&\quad BB_n^4 \\
BB_n^4 &= \bar{d}\langle \langle \text{tally}_1, \dots, \text{tally}_\ell \rangle \rangle \cdot BB_n^5 \\
BB_n^5 &= d\langle y_{\text{partial}} \rangle \cdot BB_n^6 \\
BB_n^6 &= \bar{c}\langle y_{\text{partial}} \rangle \cdot BB_n^7 \\
BB_n^7 &= \bar{c}\langle \langle \text{dec}(\pi_1(y_{\text{partial}}), \text{tally}_\ell), \dots, \text{dec}(\pi_\ell(y_{\text{partial}}), \text{tally}_\ell) \rangle \rangle \rangle \\
\\
T_\ell^1 &= \bar{d}\langle \text{partials} \rangle
\end{aligned}$$

where  $\text{partials} = (\text{partial}(sk_T, \text{tally}_1), \dots, \text{partial}(sk_T, \text{tally}_\ell))$  and  $\text{results} = (\text{dec}(\text{partial}(sk_T, \text{tally}_1), \text{tally}_1), \dots, \text{dec}(\text{partial}(sk_T, \text{tally}_\ell), \text{tally}_\ell))$ .

---

must be  $\text{penc}$  or  $\text{partial}$ . Assume first that the head symbol of  $x\phi'_e\tau$  is  $\text{penc}$ . Then by construction of  $\phi'_e$ ,  $\tau$  does not change the randomness used in  $\text{penc}$  and the randomness uniquely determines the variable, which implies  $x = y$ , contradiction. Assume now that the head symbol of  $x\phi'_e\tau$  is  $\text{partial}$ . Then it must be the case that  $\text{tally}_{j_1}\sigma_{\tilde{N}_k}\tau =_{E'} \text{tally}_{j_2}\sigma_{\tilde{N}_k}\tau$  while  $\text{tally}_{j_1}\sigma_{\tilde{N}_k} \neq_{E'} \text{tally}_{j_2}\sigma_{\tilde{N}_k}$ . This would require  $x_{\text{ciph}_{i,j_1}}\tau = x'_{\text{ciph}_{i',j_2}}\tau$  for some  $i, i'$ , which is excluded due to the randomness.  $\square$

## B.4 Proof of Theorem 1

We introduce some partial evolutions of the Helios process specification in Figure 6 and define a relation  $\mathcal{R}$  between processes in Figure 7. We clearly have that

---

**Figure 7** Definition of the relation  $\mathcal{R}$

---

Consider the smallest relation  $\mathcal{R}$  which is closed under structural equivalence and includes the following pairs of extended processes, where for all  $3 \leq j \leq n$ , terms  $M$ , terms  $N_1, \dots, N_j$ , substitutions  $\sigma = \{N_k/y_k \mid k \in \{3, \dots, n\}\}$  and distinct variables  $x_{\text{partial}}, x_{\text{result}}, x_1, x_2$  such that  $N_j\sigma\tau_L$  and  $N_j\sigma\tau_R$  are valid ballot,  $\text{fv}(M) \cup \bigcup_{3 \leq i \leq j} \text{fv}(N_i) \subseteq \text{dom}(A^4)$  and  $(\text{fn}(M) \cup \bigcup_{3 \leq i \leq j} \text{fn}(N_i)) \cap \text{bn}(A^4) = \emptyset$ .

$$A_{\ell,n}^{\phi_{\text{sol}}}[V\{a_1/x_{\text{auth}}\}\sigma \mid V\{a_2/x_{\text{auth}}\}\sigma'], \quad A_{\ell,n}^{\phi_{\text{sol}}}[V\{a_1/x_{\text{auth}}\}\sigma' \mid V\{a_2/x_{\text{auth}}\}\sigma] \quad (\text{R1})$$

$$A^1[V\{a_2/x_{\text{auth}}\}\sigma' \mid BB_n^1 \mid T_\ell]\tau_L, \quad A^1[V\{a_2/x_{\text{auth}}\}\sigma \mid BB_n^1 \mid T_\ell]\tau_R \quad (\text{R2})$$

$$A^2[V\{a_2/x_{\text{auth}}\}\sigma' \mid BB_n^2 \mid T_\ell]\tau_L, \quad A^2[V\{a_2/x_{\text{auth}}\}\sigma \mid BB_n^2 \mid T_\ell]\tau_R \quad (\text{R3})$$

$$A^3[BB_n^3 \mid T_\ell]\tau_L, \quad A^3[BB_n^3 \mid T_\ell]\tau_R \quad (\text{R4})$$

$$A^4[BB'_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\} \mid T_\ell]\tau_L, \\ A^4[BB'_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\} \mid T_\ell]\tau_R \quad (\text{R5})$$

$$A^4[BB''_{j,n}\{N_k/y_k \mid k \in \{3, \dots, j-1\}\}\{M/y_j\} \mid T_\ell]\tau_L, \\ A^4[BB''_{j,n}\{N_k/y_k \mid k \in \{3, \dots, j-1\}\}\{M/y_j\} \mid T_\ell]\tau_R \quad (\text{R6})$$

$$A^4[0 \mid T_\ell]\tau_L, \quad A^4[0 \mid T_\ell]\tau_R \quad (\text{R7})$$

$$A^4[BB_n^4\tau \mid T_\ell]\tau_L, \quad A^4[BB_n^4\tau \mid T_\ell]\tau_R \quad (\text{R8})$$

$$A^4[BB_n^5 \mid T_\ell^1]\tau\tau_L, \quad A^4[BB_n^5 \mid T_\ell^1]\tau\tau_R \quad (\text{R9})$$

$$A^5[BB_n^6]\tau\tau_L, \quad A^5[BB_n^6]\tau\tau_R \quad (\text{R10})$$

$$A^6[BB_n^7]\tau\tau_L, \quad A^6[BB_n^7]\tau\tau_R \quad (\text{R11})$$

$$A^7\tau\tau_L, \quad A^7\tau\tau_R \quad (\text{R12})$$

---

$A_{\ell,n}^{\phi}[V\{a_1/x_{\text{auth}}\}\sigma \mid V\{a_2/x_{\text{auth}}\}\sigma'] \mathcal{R} A_{\ell,n}^{\phi}[V\{a_1/x_{\text{auth}}\}\sigma' \mid V\{a_2/x_{\text{auth}}\}\sigma]$ . We now wish to show that  $\mathcal{R} \cup \mathcal{R}^{-1}$  satisfies the three properties of Definition 2. By symmetry we focus on  $\mathcal{R}$ . Overwriting the definition, we may say that a term  $N$  is a valid ballot if both  $N\sigma\tau_L$  and  $N\sigma\tau_R$  are valid ballots, where  $\sigma$  is defined

Figure 7.

**Static equivalence.** We must show for all extended processes  $A$  and  $B$ , where  $A \mathcal{R} B$ , that  $A \approx_s B$ . By Lemma 4, it is sufficient to show  $A^7 \tau \tau_L \approx_s A^7 \tau \tau_R$  for any  $N_3, \dots, N_n$  valid ballots. Let  $\phi_7 = \nu sk_T, d, r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell} \cdot (\{ballot_1/x_1\} \mid \{ballot_2/x_2\} \mid \{pk(sk_T)/z_{pk}\} \mid \{(partial_1, \dots, partial_n)/x_{partial}\} \mid \{(result_1, \dots, result_n)/x_{result}\})$ . We have to show  $\phi_7 \sigma_{N_3, \dots, N_n} \tau_L \approx_s \phi_7 \sigma_{N_3, \dots, N_n} \tau_R$ . By Lemma 9, we deduce that  $(result_1, \dots, result_\ell) \sigma_{N_3, \dots, N_n} \tau_L = (result_1, \dots, result_\ell) \sigma_{N_3, \dots, N_n} \tau_R$  and is equal to a constant (always deducible) term. Thus by Lemma 3, it is sufficient to show that  $\phi_6 \sigma_{N_3, \dots, N_n} \tau_L \approx_s \phi_6 \sigma_{N_3, \dots, N_n} \tau_R$ , where  $\phi_6$  as defined in Lemma 10. We conclude by Lemma 10.

**Internal reductions.** We must show for all extended processes  $A$  and  $B$ , where  $A \mathcal{R} B$ , that if  $A \rightarrow A'$  for some  $A'$ , then  $B \rightarrow^* B'$  and  $A' \mathcal{R} B'$  for some  $B'$ . We observe that if  $A \equiv A^1[V\{a_2/x_{auth}\}\sigma \mid BB_n^1 \mid T_\ell] \tau_L$  and  $B \equiv A^1[V\{a_2/x_{auth}\}\sigma \mid BB_n^1 \mid T_\ell] \tau_R$  – that is,  $A \mathcal{R} B$  by (R2) – then there is no extended process  $A'$  such that  $A \rightarrow A'$ ; similarly, for (R4), (R5), (R7), (R10), (R11) and (R12). We proceed by case analysis on the remaining cases.

- (R1) We have  $A \equiv A_{\ell,n}^{\phi_{sol}}[V\{a_1/x_{auth}\}\sigma \mid V\{a_2/x_{auth}\}\sigma']$  and  $B \equiv A_{\ell,n}^{\phi_{sol}}[V\{a_1/x_{auth}\}\sigma' \mid V\{a_2/x_{auth}\}\sigma]$ . If  $A \rightarrow A'$ , then it must be the case that  $A \equiv C[\bar{a}_1 \langle y_1 \rangle . 0 \mid a_1(y_1).BB_n^1] \tau_L$  and  $A' \equiv C[0 \mid BB_n^1] \tau_L$ , where  $C[\_] = A^1[\nu a_1.(- \mid V\{a_2/x_{auth}\}\sigma' \mid T_\ell)]$ . It follows from  $B \equiv C'[\bar{a}_1 \langle y_1 \rangle . 0 \mid a_1(y_1).BB_n^1] \tau_R$ , that  $B \rightarrow B'$ , where  $C'[\_] = A^1[\nu a_1.(- \mid V\{a_2/x_{auth}\}\sigma \mid T_\ell)]$  and  $B' = A^1[V\{a_2/x_{auth}\}\sigma \mid BB_n^1 \mid T_\ell] \tau_R$ . Since  $A^1[V\{a_2/x_{auth}\}\sigma' \mid BB_n^1 \mid T_\ell] \tau_L \mathcal{R} B'$  and  $A' \equiv A^1[V\{a_2/x_{auth}\}\sigma' \mid BB_n^1 \mid T_\ell] \tau_L$ , we derive  $A' \mathcal{R} B'$  by the closure of  $\mathcal{R}$  under structural equivalence.
- (R3) This case is similar to (R1). We have  $A \equiv A^2[V\{a_2/x_{auth}\}\sigma' \mid BB_n^2 \mid T_\ell] \tau_L$  and  $B \equiv A^2[V\{a_2/x_{auth}\}\sigma \mid BB_n^2 \mid T_\ell] \tau_R$ . If  $A \rightarrow A'$ , then it must be the case that  $A \equiv C[\bar{a}_2 \langle y_2 \rangle . 0 \mid a_2(y_2).BB_n^3] \tau_L$  and  $A' \equiv C[0 \mid BB_n^3] \tau_L$ , where  $C[\_] = A^3[\nu a_2.(- \mid T_\ell)]$ . It follows from  $B \equiv C[\bar{a}_2 \langle y_2 \rangle . 0 \mid a_2(y_2).BB_n^3] \tau_R$ , that  $B \rightarrow B'$ , where  $B' = A^3[BB_n^3 \mid T_\ell] \tau_R$ . Since  $A^3[BB_n^3 \mid T_\ell] \tau_L \mathcal{R} B'$  and  $A' \equiv A^3[BB_n^3 \mid T_\ell] \tau_L$ , we derive  $A' \mathcal{R} B'$  by the closure of  $\mathcal{R}$  under structural equivalence.
- (R6) We have  $A \equiv A^4[BB_{j,n}''\{N_k/y_k \mid k \in \{3, \dots, j-1\}\}\{M/y_j\} \mid T_\ell] \tau_L$  and  $B \equiv A^4[BB_{j,n}''\{N_k/y_k \mid k \in \{3, \dots, j-1\}\}\{M/y_j\} \mid T_\ell] \tau_R$  for some integer  $j \in \{3, \dots, n\}$ , valid ballots  $N_3, \dots, N_{j-1}$  and term  $M$  such that  $\text{fv}(M) \cup \bigcup_{3 \leq i \leq j-1} \text{fv}(N_i) \subseteq \text{dom}(A^4)$  and  $(\text{fn}(M) \cup \bigcup_{3 \leq i \leq j-1} \text{fn}(N_i)) \cap \text{bn}(A^4) = \emptyset$ . If  $A \rightarrow A'$ , then it must be the case that  $A \equiv C[\text{if } \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}, ballot_1/y_1, ballot_2/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\} \text{ then } P \text{ else } 0] \tau_L$ , where  $C[\_] = A^4[\_ \mid T_\ell]$ . Furthermore, if  $j < n$ , then  $P = BB_{j+1,n}'\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\}\{M/y_j\}$ ; otherwise  $P = BB_n^4\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots,$

$j-1\}\{M/y_j\}$ . We also have  $B \equiv C[\text{if } \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}, \text{ballot}_1/y_1, \text{ballot}_2/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\} \text{ then } P \text{ else } 0]\tau_R$ .

Let  $\sigma_R = \{\text{ballot}_1\tau_R/x_1, \text{ballot}_2\tau_R/x_2, \text{pk}(sk_T)/z_{\text{pk}}\}$ , we have  $\text{ballot}_1\tau_R$  is syntactically equal to  $x_1\sigma_R$  and  $\text{ballot}_2\tau_R$  is syntactically equal to  $x_2\sigma_R$ , it follows that  $B \equiv C[\text{if } \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}, x_1\sigma_R/y_1, x_2\sigma_R/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\} \text{ then } P \text{ else } 0]\tau_R$  and, moreover, since  $\varphi(C[0]\tau_R) = \nu sk_T, d, r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}, y_1, y_2.\sigma_R$  we have  $B \equiv C[\text{if } \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}, x_1/y_1, x_2/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\} \text{ then } P \text{ else } 0]\tau_R$ . We proceed by case analysis on the structure of  $A'$ :

- If  $A' \equiv C[P]\tau_L$ , then by closure of internal reduction under structural equivalence we have  $C[\text{if } \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}, x_1/y_1, x_2/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\} \text{ then } P \text{ else } 0]\tau_L \rightarrow C[P]\tau_L$  because  $\text{ballot}_1\tau_L$  is syntactically equal to  $x_1\sigma_L$ ,  $\text{ballot}_2\tau_L$  is syntactically equal to  $x_2\sigma_L$  and  $\varphi(C[0]\tau_L) = \nu sk_T, d, r_{1,1}, \dots, r_{1,\ell}, r_{2,1}, \dots, r_{2,\ell}, y_1, y_2.\sigma_L$ , where  $\sigma_L = \{\text{ballot}_1\tau_L/x_1, \text{ballot}_2\tau_L/x_2, \text{pk}(sk_T)/z_{\text{pk}}\}$ .

Assume  $A$  and  $B$  satisfy the preconditions of Corollary 1, it follows that  $B \rightarrow B' = A^4[P \mid T_\ell]\tau_R$ . We now prove our assumption. Since  $A \mathcal{R} B$ , it follows by Condition 1 of Definition 2 that  $A \approx_s B$ . Let  $\phi = \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}, x_1/y_1, x_2/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\}$ . By inspection of  $\phi_{\ell,j-1}^{\text{sol}}$ , we have  $\text{fn}(\phi) = \text{fn}(M) \cup \bigcup_{3 \leq i \leq j-1} \text{fn}(N_i)$  and since  $\text{bn}(C) = \text{bn}(A^4)$  it follows that  $\text{bn}(C) \cap \text{fn}(\phi) = \emptyset$ ; we also have  $\text{fv}(\phi) = \{x_1, x_2, z_{\text{pk}}\} \cup \text{fv}(M) \cup \bigcup_{3 \leq i \leq j-1} \text{fv}(N_i)$  and since  $\text{dom}(C) = \{x_1, x_2, z_{\text{pk}}\}$  it follows that  $\text{fv}(\phi) \subset \text{dom}(C)$ . We have shown that the preconditions of Corollary 1 are satisfied, hence  $B \rightarrow B' = A^4[P \mid T_\ell]\tau_R$ . It remains to show  $A' \mathcal{R} B'$ .

We know  $\llbracket \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}, x_1/y_1, x_2/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\}\sigma_L \rrbracket = \text{true}$  and  $\llbracket \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}, x_1/y_1, x_2/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\}\sigma_R \rrbracket = \text{true}$ ; it follows, for  $\tau \in \{\tau_L, \tau_R\}$ , that  $\llbracket \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}\}\{\text{pk}(sk_T)/z_{\text{pk}}, \text{ballot}_1/y_1, \text{ballot}_2/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\}\tau \rrbracket = \text{true}$  and we know that  $M$  is a valid ballot. We continue by case analysis on the structure of  $P$ :

1. If  $P = BB'_{j+1,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\}\{M/y_j\}$ , then we have  $j < n$ . Let  $j' = j+1$  and  $N_j = M$ , observe  $P = BB'_{j',n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j\}\}$  and  $A^4[BB'_{j',n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j\}\} \mid T_\ell]\tau_L \mathcal{R} B'$ . The result  $A' \mathcal{R} B'$  follows by closure of  $\mathcal{R}$  under structural equivalence.
  2. If  $P = BB_n^4\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\}\{M/y_j\}$ , then it must be the case that  $j = n$ . Let  $N_j = M$  and hence  $P = BB_n^4\tau$ . Since  $A^4[BB_n^4\tau \mid T_\ell]\tau_L \mathcal{R} B'$  and  $A' \equiv A^4[BB_n^4\tau \mid T_\ell]\tau_L$ , we derive  $A' \mathcal{R} B'$  by the closure of  $\mathcal{R}$  under structural equivalence.
- $A' \equiv C[0]\tau_L$ , then similarly to above we have  $C[\text{if } \phi_{\ell,j-1}^{\text{sol}}\{M/y_{\text{ballot}}, x_1/y_1, x_2/y_2, N_3/y_3, \dots, N_{j-1}/y_{j-1}\} \text{ then } P \text{ else } 0]\tau_L \rightarrow C[0]\tau_L$  and it follows by Corollary 1 that  $B \rightarrow B' = C[0]\tau_R$ . Since  $A^4[0 \mid T_\ell] \mathcal{R} B'$

and  $A' \equiv A^4[0 \mid T_\ell]$ , we derive  $A' \mathcal{R} B'$  by the closure of  $\mathcal{R}$  under structural equivalence.

- (R8) We have  $A \equiv A^4[BB_n^4 \tau \mid T_\ell]_{\tau_L}$  and  $B \equiv A^4[BB_n^4 \tau \mid T_\ell]_{\tau_R}$ , where  $BB_n^4 = \bar{d}(\langle \text{tally}_1, \dots, \text{tally}_\ell \rangle) \cdot BB_n^5$  and  $T_\ell = d(y_{\text{tally}}) \cdot \bar{d}(\langle \text{partial}(sk_T, \pi_1(y_{\text{tally}})), \dots, \text{partial}(sk_T, \pi_\ell(y_{\text{tally}})) \rangle)$ . If  $A \rightarrow A'$ , then it must be the case that  $A' \equiv A^4[BB_n^5 \mid T_\ell^1]_{\tau_{\tau_L}}$ . It follows immediately that  $B \rightarrow B'$ , where  $B' = A^4[BB_n^5 \mid T_\ell^1]_{\tau_{\tau_R}}$ . We derive  $A' \mathcal{R} B'$  by the closure of  $\mathcal{R}$  under structural equivalence.
- (R9) We have  $A \equiv A^4[BB_n^5 \mid T_\ell^1]_{\tau_{\tau_L}}$  and  $B \equiv A^4[BB_n^5 \mid T_\ell^1]_{\tau_{\tau_R}}$ . If  $A \rightarrow A'$ , then it must be the case that  $A \equiv A^5[\bar{d}(y_{\text{partial}}).0 \mid d(y_{\text{partial}}).BB_n^6]_{\tau_{\tau_L}}$  and  $A' \equiv A^5[0 \mid BB_n^6]_{\tau_{\tau_L}}$ . It follows from  $B \equiv A^5[d(y_{\text{partial}}).BB_n^6 \mid \bar{d}(y_{\text{partial}}).0]_{\tau_{\tau_R}}$  that  $B \rightarrow B'$ , where  $B' = A^5[BB_n^6]_{\tau_{\tau_R}}$ . We derive  $A' \mathcal{R} B'$  by the closure of  $\mathcal{R}$  under structural equivalence.

**Labelled reductions.** We must show for all extended processes  $A$  and  $B$ , where  $A \mathcal{R} B$ , that if  $A \xrightarrow{\alpha} A'$  such that  $\text{fv}(\alpha) \subseteq \text{dom}(A)$  and  $\text{bn}(\alpha) \cap \text{fn}(B) = \emptyset$ , then  $B \rightarrow^* \alpha \rightarrow^* B'$  and  $A' \mathcal{R} B'$  for some  $B'$ . We observe cases (R1), (R3), (R6), (R7), (R8), (R9) and (R12) cannot be reduced by labelled reductions and proceed by case analysis on the remaining cases.

- (R2) We have  $A \equiv A^1[V\{a_2/x_{\text{auth}}\}\sigma' \mid BB_n^1 \mid T_\ell]_{\tau_L}$  and  $B \equiv A^1[V\{a_2/x_{\text{auth}}\}\sigma \mid BB_n^1 \mid T_\ell]_{\tau_R}$ . If  $A \xrightarrow{\alpha} A'$  such that  $\text{fv}(\alpha) \subseteq \text{dom}(A)$  and  $\text{bn}(\alpha) \cap \text{fn}(B) = \emptyset$ , then it must be the case that  $A \equiv A^1[V\{a_2/x_{\text{auth}}\}\sigma' \mid \bar{c}(y_1).BB_n^2 \mid T_\ell]_{\tau_L}$  and  $A' \equiv A^2[V\{a_2/x_{\text{auth}}\}\sigma' \mid BB_n^2 \mid T_\ell]_{\tau_L}$  for some variable  $x_1$  where  $\alpha = \nu x_1.\bar{c}(x_1)$  and  $x_1 \neq z_{\text{pk}}$ . It follows from  $B \equiv A^1[V\{a_2/x_{\text{auth}}\}\sigma \mid \bar{c}(y_1).BB_n^2 \mid T_\ell]_{\tau_R}$ , that  $B \xrightarrow{\alpha} B'$  where  $B' = A^2[V\{a_2/x_{\text{auth}}\}\sigma \mid BB_n^2 \mid T_\ell]_{\tau_R}$ . We have  $A^2[V\{a_2/x_{\text{auth}}\}\sigma' \mid BB_n^2 \mid T_\ell]_{\tau_L} \mathcal{R} B'$  and by closure of  $\mathcal{R}$  under structural equivalence  $A' \mathcal{R} B'$ .
- (R4) We have  $A \equiv A^3[BB_n^3 \mid T_\ell]_{\tau_L}$  and  $B \equiv A^3[BB_n^3 \mid T_\ell]_{\tau_R}$ . If  $A \xrightarrow{\alpha} A'$  such that  $\text{fv}(\alpha) \subseteq \text{dom}(A)$  and  $\text{bn}(\alpha) \cap \text{fn}(B) = \emptyset$ , then it must be the case that  $A \equiv A^3[\bar{c}(y_2).BB'_{3,n} \mid T_\ell]_{\tau_L}$  and  $A' \equiv A^4[BB'_{3,n} \mid T_\ell]_{\tau_L}$  for some variable  $x_2$ , where  $\alpha = \nu x_2.\bar{c}(x_2)$  and  $x_2 \notin \{x_1, z_{\text{pk}}\}$ . It follows from  $B \equiv A^3[\bar{c}(y_2).BB'_{3,n} \mid T_\ell]_{\tau_R}$ , that  $B \xrightarrow{\alpha} B'$ , where  $B' = A^4[BB'_{3,n} \mid T_\ell]_{\tau_R}$ . Since  $A^4[BB'_{3,n} \mid T_\ell]_{\tau_L} = A^4[BB'_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\} \mid T_\ell]_{\tau_L}$  and  $A^4[BB'_{3,n} \mid T_\ell]_{\tau_R} = A^4[BB'_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\} \mid T_\ell]_{\tau_R}$  when  $j = 3$ , we have  $A^4[BB'_{3,n} \mid T_\ell]_{\tau_L} \mathcal{R} B'$  and derive  $A' \mathcal{R} B'$  by closure of  $\mathcal{R}$  under structural equivalence  $A' \mathcal{R} B'$ .
- (R5) We have  $A \equiv A^4[BB'_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\} \mid T_\ell]_{\tau_L}$  and  $B \equiv A^4[BB'_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\} \mid T_\ell]_{\tau_R}$  for some integer  $j \in \{3, \dots, n\}$  and terms  $N_3, \dots, N_{j-1}$ , where  $\bigcup_{3 \leq i \leq j-1} \text{fv}(N_i) \subseteq \text{dom}(A^4)$  and  $\text{bn}(A^4) \cap \bigcup_{3 \leq i \leq j-1} \text{fn}(N_i) = \emptyset$ . If  $A \xrightarrow{\alpha} A'$  such that  $\text{fv}(\alpha) \subseteq \text{dom}(A)$  and  $\text{bn}(\alpha) \cap \text{fn}(B) = \emptyset$ , then it must be the case that

$A \equiv A^4[a_j(y_j).BB''_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\} \mid T_\ell]_{\tau_L}$  and  $A' \equiv A^4[BB''_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\}\{M/y_j\} \mid T_\ell]_{\tau_L}$ , where  $\alpha = c(M)$  for some term  $M$ . It follows from  $B \equiv A^4[a_j(y_j).BB''_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\} \mid T_\ell]_{\tau_R}$ , that  $B \xrightarrow{\alpha} B'$ , where  $B' = A^4[BB''_{j,n}\{N_k/y_k \mid j > 3 \wedge k \in \{3, \dots, j-1\}\}\{M/y_j\} \mid T_\ell]_{\tau_R}$ . We have  $A^4[BB''_{j,n}\{N_k/y_k \mid k \in \{3, \dots, j-1\}\}\{M/y_j\} \mid T_\ell]_{\tau_L} \mathcal{R} B'$ , and derive  $A' \mathcal{R} B'$  by closure of  $\mathcal{R}$  under structural equivalence.

(R10) We have  $A \equiv A^5[BB_n^6]_{\tau\tau_L}$  and  $B \equiv A^5[BB_n^6]_{\tau\tau_R}$ . If  $A \xrightarrow{\alpha} A'$  such that  $\text{fv}(\alpha) \subseteq \text{dom}(A)$  and  $\text{bn}(\alpha) \cap \text{fn}(B) = \emptyset$ , then it must be the case that  $A' \equiv A^6[BB_n^7]_{\tau\tau_L}$  for some variable  $x_{\text{partial}}$ , where  $\alpha = \nu x_{\text{partial}}.\bar{c}\langle x_{\text{partial}} \rangle$  and  $x_{\text{partial}} \notin \{x_1, x_2, z_{\text{pk}}\}$ . It follows immediately that  $B \xrightarrow{\alpha} B'$ , where  $B' = A^6[BB_n^7]_{\tau\tau_R}$ . We have  $A^6[BB_n^7]_{\tau\tau_L} \mathcal{R} B'$  and by closure of  $\mathcal{R}$  under structural equivalence  $A' \mathcal{R} B'$ .

(R11) This case is similar to (R10). We have  $A \equiv A^6[BB_n^7]_{\tau\tau_L}$  and  $B \equiv A^6[BB_n^7]_{\tau\tau_R}$ . If  $A \xrightarrow{\alpha} A'$  such that  $\text{fv}(\alpha) \subseteq \text{dom}(A)$  and  $\text{bn}(\alpha) \cap \text{fn}(B) = \emptyset$ , then it must be the case that  $A' \equiv A^7\tau\tau_L$  for some variable  $x_{\text{result}}$ , where  $\alpha = \nu x_{\text{result}}.\bar{c}\langle x_{\text{result}} \rangle$  and  $x_{\text{result}} \notin \{x_1, x_2, x_{\text{partial}}, z_{\text{pk}}\}$ . It follows immediately that  $B \xrightarrow{\alpha} B'$ , where  $B' = A^7\tau\tau_R$ . We have  $A^7\tau\tau_L \mathcal{R} B'$  and by closure of  $\mathcal{R}$  under structural equivalence  $A' \mathcal{R} B'$ .
