Abstract. In [12] a Zero-Knowledge scheme ZK(2) was designed from a solution of a set of multivariate quadratic equations over a finite field. In this paper we will give two methods to generalize this construction for polynomials of any degree d, i.e. we will design two Zero-Knowledge schemes ZK(d) and $\tilde{ZK}(d)$ from a set of polynomial equations of degree d. We will show that $\tilde{ZK}(d)$ is optimal in term of the number of computations to be performed and that ZK(d) is optimal in term of the number of bits to be send. Moreover this property is still true for all kinds of polynomials: for example if the polynomials are sparse or dense. Finally, we will present two examples of applications: with Brent equations, or with morphisms of polynomials.

Key words: Authentication scheme, Zero-Knowledge, Multivariate polynomials.

1 Introduction

The first Zero-Knowledge schemes were based on the factorization problem (for example Fischer-Micali-Rackoff in 1984, or Fiat-Shamir in 1986) or the Graph Isomorphism Problem. However the factorization problem is not expected to be a NP complete problem (since it is in NP and Co NP) and it has sub-exponential algorithms (such as NFS) and even polynomial algorithms on quantum computers (Shor algorithm). Then, it was proved in 1991 by O. Goldreich, S. Micali and A. Widgerson that any problem of NP has a Zero-Knowledge proof ([4]). But the general construction (cf [4]) of Zero-Knowledge proofs from any problem of NP is usually not very efficient. This is why various Zero-Knowledge schemes have been specifically designed from some well suited and well chosen NP complete schemes based on simple combinatorial problems expected to be exponentially difficult, such as PKP of Adi Shamir [13], PP of David Pointcheval [11] or CLE [15] or SD [14] of Jacques Stern for example. Recently ([12]) such a scheme was designed from the MQ problem, i.e. the problem of finding a solution from a set of multivariate quadratic equations over a finite field. This MQ problem is related to various primitives in cryptography [2, 7–9], and is NP-complete over any finite field ([3, 10]).

In this paper, we will generalize the construction of [12] in order to design a Zero-Knowledge authentication from a solution of any set of multivariate polynomials of degree d over a finite field (i.e. not only d = 2). We will describe two schemes extending the results of [12]. The Zk(d) scheme is optimal if we focus on the number of bits to be sent and the ZK(d) scheme is optimal if we consider the number of computations. This is true for any kind of polynomials (dense or sparse). For practical applications the case d = 3 (i.e. cubic equations) is particularly important, since from these polynomials we will be able to design Zero-Knowledge schemes based on the (NP-complete) Morphism problem (MP) or from the Brent equations related to the optimal way to solve sets of linear equations (i.e. improvements of the Gauss elimination). We will explain in this paper why these two problems are really interesting for cryptography. We can notice that MP (morphism of Polynomial) is NP hard while IP (isomorphism of Polynomials) is expected not to be NP hard (since it has an Arthur-Merlin game for yes or no answers). We will detail the case d = 3 and give only the features of the general schemes ZK(d) and ZK(d).

2 Zero-Knowledge Protocols and Commitments

In an interactive Protocol, there are two entities: the prover and the verifier. The Prover wants to convince the verifier that she knows a secret. Both interact and at the end, the verifier accepts or refuses. In Zero-Knowledge Protocols there is a possibility of fraud. A cheater will be able to answer some of the questions (but not all of them). The protocol must be designed such that an answer to one of the question does not give any indication on the secret but if someone is able to answer all the questions then this will reveal the Prover's secret. We will use the following definitions in order to describe the properties that we want to be satisfied by our protocols:

- 1. The protocol has **perfect correctness** is a legitimate prover is always accepted.
- 2. The protocol is **statistically zero knowledge** if there exists an efficient simulating algorithm U such that for every feasible Verifier strategy V, the distributions produced by the simulator and the proof protocol are statistically indistinguishable.
- 3. The protocol is **proof of zero knowledge with error knowledge** α if there is a knowledge extractor K and a polynomial Q such that if p denotes the probability that K finds a valid witness for x using its access to a prover P^* and p_x denotes the probability that P^* convinces the honest verifier on x, and $p_x > \alpha$, then we have $p \ge Q(p_x - \alpha)$.

In our protocols, we will need string commitment schemes. A string commitment function is denoted by Com. The commitment scheme runs in two phases. In the first phase, the sender computes a commitment value $c = Com(s; \rho)$ and sends c to the receiver, where s is the committed string and ρ is a random string. In the second phase, the sender gives (s, ρ) and the receiver verifies if $c = Com(s; \rho)$. we require the two following properties of Com.

- 1. The commitment scheme is **statistically hiding** if for uniform (x, ρ) and (x', ρ') the distributions $Com(s, \rho)$ and $Com(x', \rho')$ are statistically indistinguishable. This means that the commitment to x reveals (almost) no information on x even to an infinitely powerful Verifier.
- 2. The commitment scheme is **computationally binding** if the probability to that two different values (x, ρ) and (x', ρ') produce the same $c = Com(x, \rho) = Com(x', \rho')$ is negligible in polynomial time, i.e. the chances to change the committed value after the first phase are very small.

A practical construction of such a commitment is given in [5].

3 Systems of Multivariate equations of degree d

We consider the following function of degree d from \mathbb{F}_q^n to \mathbb{F}_q^m :

$$F(x) = (f_1(x), f_2(x), \dots, f_m(x))$$

where $\forall \ell, 1 \leq \ell \leq m$, and $x = (x_1, \ldots, x_n)$:

$$f_{\ell}(x) = \sum_{1 \le i_1 \le \dots \le i_d \le n} \gamma_{i_1 \dots i_d}^{\ell} x_{i_1} x_{i_2} \dots x_{i_d} + \sum_{1 \le i_1 \le \dots \le i_{d-1} \le n} \gamma_{i_1 \dots i_{d-1}}^{\ell} x_{i_1} x_{i_2} \dots x_{i_{d-1}} + \dots + \sum_{1 \le i_1 \le i_2 \le n} \gamma_{i_1 i_2}^{\ell} x_{i_1} x_{i_2} + \sum_{1 \le i_1 \le n} \gamma_{i_1}^{\ell} x_{i_1}$$

We omit the constant term. Let

$$G(r_0, r_1, \dots, r_{d-1}) = \sum_{i=1}^d (-1)^{d-i} \sum_{\substack{S \subset \{0, \dots, d-1\} \\ |S|=i}} F(\sum_{j \in S} r_j)$$

Then G is d-linear. For F, a multivariate function of degree d, we define a binary relation $R_F = \{(v, x) \in \mathbb{F}_q^m \times \mathbb{F}_q^n; v = F(x)\}$. The problem is: Given F and $v \in \mathbb{F}_q^m$ find $s \in \mathbb{F}_q^n$ such that F(s) = v, i.e. $s \in R_F(v)$.

4 ZK(3) Schemes

We consider the following cubic functions: $F(x) = (f_1(x), f_2(x), \dots, f_m(x))$ where $\forall \ell, 1 \leq \ell \leq m$ and $x = (x_1, \dots, x_n)$

$$f_{\ell}(x) = \sum_{1 \le i \le j \le k \le n} \gamma_{ijk}^{\ell} x_i x_j x_k + \sum_{1 \le i \le j \le n} \gamma_{ij}^{\ell} x_i x_j + \sum_{1 \le i \le n} \gamma_i^{\ell} x_i$$

We omit the constant term. Let

$$G(x,y,z) = F(x+y+z) - F(x+y) - F(x+z) - F(y+z) + F(x) + F(y) + F(z)$$

We have: $G(x, y, z) = (g_1(x, y, z), g_2(x, y, z), \dots, g_m(x, y, z))$ where $\forall \ell, 1 \le \ell \le m, x = (x_1, \dots, x_n), y = (y_1, \dots, y_n)$ and $z = (z_1, \dots, z_n)$

$$g_{\ell}(x, y, z) = \sum_{1 \le i \le j \le k \le n} \gamma_{ijk}^{\ell} (x_i y_j z_k + x_i y_k z_j + x_j y_i z_k + x_j y_k z_i + x_k y_i z_j + x_k y_j z_i)$$

Then G is trilinear.

The problem is: Given F and $v \in \mathbb{F}_q^m$ find $s \in \mathbb{F}_q^n$ such that F(s) = v. The public key is (F, v). The secret is s such that F(s) = v. The Prover is going to convince the Verifier of his knowledge of s.

4.1 3-pass scheme

For simplicity, the random string in *Com* is not written explicitly. If X is a set, $x \in_R E$ means that x is randomly chosen in X with the uniform distribution.

1. The Prover picks up $r_0, r_1, t_0 \in_R \mathbb{F}_q^n$ and $e_0, f_0, h_0 \in_R \mathbb{F}_q^m$. Then she computes

$$\begin{aligned} r_2 &= s - r_1 - r_0, \ t_1 &= r_0 - t_0 \\ e_1 &= F(r_0) - e_0, \ f_1 &= F(r_0 + r_1) - f_0, \ h_1 &= F(r_0 + r_2) - h_0 \end{aligned}$$

The Prover sends to the Verifier

 $\begin{array}{l} c_0 = Com(r_1,r_2,G(t_0,r_1,r_2)-e_0+f_0+h_0)\\ c_1 = Com(r_1,t_0,e_0,f_0), \ c_2 = Com(r_1,t_1,e_1,f_1)\\ c_3 = Com(r_2,t_0,e_0,h_0), \ c_4 = Com(r_2,t_1,e_1,h_1) \end{array}$

- 2. The verifier chooses a query $\mathcal{Q} \in_R \{0, 1, 2, 3\}$ and sends \mathcal{Q} to the prover.
- 3. (a) If $\mathcal{Q} = 0$ then the Prover sends $(r_0, r_1, t_1, e_1, f_1)$. The Verifier checks if $c_1 = Com(r_1, r_0 t_1, F(r_0) e_1, F(r_0 + r_1) f_1), c_2 = Com(r_1, t_1, e_1, f_1)$
 - (b) If Q = 1 then the Prover sends $(r_0, r_2, t_1, e_1, h_1)$. The Verifier checks if $c_3 = Com(r_2, r_0 t_1, F(r_0) e_1, F(r_0 + r_2) h_1), c_4 = Com(r_2, t_1, e_1, h_1)$
 - (c) If Q = 2 then the Prover sends $(r_1, r_2, t_1, e_1, f_1, h_1)$. The Verifier checks if $c_0 = Com(r_1, r_2, v G(t_1, r_1, r_2) + e_1 f_1 h_1 F(r_1 + r_2) + F(r_1) + F(r_2)), c_2 = Com(r_1, t_1, e_1, f_1), c_4 = Com(r_2, t_1, e_1, h_1)$
 - (d) If Q = 3 then the Prover sends $(r_1, r_2, t_0, e_0, f_0, h_0)$. The Verifier checks if $c_0 = Com(r_1, r_2, G(t_0, r_1, r_2) - e_0 + f_0 + h_0), c_1 = Com(r_1, t_0, e_0, f_0), c_3 = Com(r_2, t_0, e_0, h_0)$

The verifier outputs 1 if the she gets the correct value in the commitments, 0 otherwise.

4.2 Properties of the 3-pass scheme

It is easy to see that the verifier always accepts an interaction with the honest prover. Thus the 3-pass scheme has perfect correctness.

Theorem 1 The 3-pass protocol is statistically zero knowledge when the commitment scheme Com is statistically hiding.

Proof. We construct a black-box simulator \mathcal{S} which have oracle access to a cheating verifier \mathcal{CV} takes F and v, and outputs a simulated transcripts with probability 3/4 as follows. The simulator randomly chooses a value $\mathcal{Q}^* \in_R \{0, 1, 2, 3\}$ and vectors $s', r'_0, r'_1, t'_0 \in_R \mathbb{F}_q^n$ and $e'_0, f'_0, h'_0 \in_R \mathbb{F}_q^m$, where \mathcal{Q}^* is a prediction what value the cheating verifier \mathcal{CV} will not choose. Then it computes

$$r_2' = s' - (r_0' + r_1'), \ t_1' \leftarrow r_0' - t_0', \ e_1' \leftarrow F(r_0') - e_0'$$

Moreover it sets:

1. If $Q^* = 0$, $f'_1 = v - F(s') + F(r'_0 + r'_1) - f'_0$, else $f'_1 = F(r'_0 + r'_1) - f'_0$. 2. If $Q^* = 1$, $h'_1 = v - F(s') + F(r'_0 + r'_2) - f'_0$, else $h'_1 = F(r'_0 + r'_2) - h'_0$. 3. If $Q^* = 3$, $c'_0 = Com(r'_1, r'_2, v - G(t'_1, r'_1, r'_2) - f'_1 - h'_1 + e'_1 - F(r'_1 + r'_2) + F(r'_1) + F(r'_2))$, else $c'_0 = Com(r'_1, r'_2, G(t'_0, r'_1, r'_2) - f'_0 - h_0 + e'_0)$

It also computes:

$$\begin{array}{l} c_1' = Com(r_1',t_0',e_0',f_0'), \ c_2' = Com(r_1',t_1',e_1',f_1') \\ c_3' = Com(r_2',t_0',e_0',h_0'), \ c_4' = Com(r_2',t_1',e_1',h_1') \end{array}$$

and sends $(c'_0, c'_1, c'_2, c'_3, c'_4)$ to \mathcal{CV} .

Receiving a query \mathcal{Q} from \mathcal{CV} the simulator outputs \perp if $\mathcal{Q} = \mathcal{Q}^*$ and stops. If S does not output \perp , it produces a transcript as follows:

- If Q = 0, it outputs $((c'_0, c'_1, c'_2, c'_3, c'_4), 0, (r'_0, r'_1, t'_1, e'_1, f'_1))$
- If Q = 1, it outputs $((c'_0, c'_1, c'_2, c'_3, c'_4), 1, (r'_0, r'_2, t'_1, e'_1, h'_1))$
- $\text{ If } \mathcal{Q} = 2, \text{ it outputs } ((c'_0, c'_1, c'_2, c'_3, c'_4), 2, (r'_1, r'_2, t'_1, e'_1, f'_1, h'_1)) \\ \text{ If } \mathcal{Q} = 3, \text{ it outputs } ((c'_0, c'_1, c'_2, c'_3, c'_4), 3, (r'_1, r'_2, t'_0, e'_0, f'_0, h'_0))$

We can check that if \mathcal{S} does not output \perp , the transcript is accepted. For example, we consider the case where $Q^* = 0$ and Q = 2. The output is $((c'_0, c'_1, c'_2, c'_3, c'_4, c'_3, c'_4, c'_4, c'_3, c'_3, c'_4, c'_4, c'_4, c'_3, c'_4, c'_4,$ c'_4), 2, $(r'_1, r'_2, t'_1, e'_1, f'_1, h'_1)$). Thus, we have the right values for c'_2 and c'_4 . Now, c'_0 is computed as follows: $c'_0 = Com(r'_1, r'_2, v - G(t'_1, r'_1, r'_2) + e'_1 - f'_1 - h'_1 - F(r'_1 + r'_2) + F(r'_1) + f(r'_2)$). Here $f'_1 = v - F(s') + F(r'_0 + r'_1) - f'_0$. Thus we obtain $c'_0 = Com(r'_1, r'_2, G(t'_0, r'_1, r'_2) - f'_0 - h_0 + e'_0)$ and the transcript is accepted. The other cases are checked similarly.

We now show that the distribution of the output \mathcal{S} is statistically close to the distribution of a real transcript since the commitment is statistically hiding. A real transcript between the the legitimate prover P and a cheating verifier \mathcal{CV} on (F, v, s) is denoted by $\langle P(s), \mathcal{CV} \rangle (F, v)$. The simulator output is denoted by $\langle \mathcal{S}, \mathcal{CV} \rangle (F, v)$. We analyze the output distribution.

First first we consider the case where Q = 0. Then

$$\langle P(s), \mathcal{CV} \rangle (F, v) = ((c_0, c_1, c_2, c_3, c_4), 0, (r_0, r_1, t_1, e_1, f_1)) \\ \langle \mathcal{S}, \mathcal{CV} \rangle (F, v) = ((c'_0, c'_1, c'_2, c'_3, c'_4), 0, (r'_0, r'_1, t'_1, e'_1, f'_1))$$

Assume that $(r'_0, r'_1, t'_0, e'_0, f'_0) = (r_0, r_1, t_0, e_0, f_0)$. Then we obtain $t'_1 = t_1, e'_1 = e_1, f'_1 = f_1$ and $c'_1 = c_1, c'_2 = c_2$ in all cases $Q^* = 1, 2, 3$. The second case is when Q = 1. Then

$$\langle P(s), \mathcal{CV} \rangle (F, v) = ((c_0, c_1, c_2, c_3, c_4), 1, (r_0, r_2, t_1, e_1, h_1)) \langle \mathcal{S}, \mathcal{CV} \rangle (F, v) = ((c'_0, c'_1, c'_1, c'_3, c'_4), 1, (r'_0, r'_2, t'_1, e'_1, h'_1))$$

This case is very similar to the previous one. We get $t'_1 = t_1$, $e'_1 = e_1$, $h'_1 = h_1$ and $c'_3 = c_3$, $c'_4 = c_4$ in all cases $Q^* = 0, 2, 3$. The third case is Q = 2. Then

$$\langle P(s), \mathcal{CV} \rangle (F, v) = ((c_0, c_1, c_2, c_3, c_4), 2, (r_1, r_2, t_1, e_1, f_1, h_1)) \langle \mathcal{S}, \mathcal{CV} \rangle (F, v) = ((c'_0, c'_1, c'_2, c'_3, c'_4), 2, (r'_1, r'_2, t'_1, e'_1, f'_1, h'_1))$$

When $Q^* = 0$, assume that $(r'_0, r'_1, t'_0, e'_0, f'_0, h'_0) = (r_0 + s' - s, r_1, t_0 + s' - s, e_0 - F(r_0) + F(r_0 + s' - s), f_0 - F(r_0 + r_1) + v - F(s') + F(r_0 + r_1 + s' - s), h_0 - F(r_0 + r_2) + F(r_0 + r_2 + s' - s))$. When $Q^* = 1$, assume that $(r'_0, r'_1, t'_0, e'_0, f'_0, h'_0) = (r_0 + s' - s, r_1, t_0 + s' - s, e_0 - F(r_0) + F(r_0 + s' - s), f_0 - F(r_0 + r_1) + F(r_0 + r_1 + s' - s), h_0 - F(r_0 + r_2) + v - F(s') + F(r_0 + r_2 + s' - s))$. When $Q^* = 1$, assume that $(r'_0, r'_1, t'_0, e'_0, f'_0, h'_0) = (r_0 + s' - s, r_1, t_0 + s' - s, e_0 - F(r_0) + F(r_0 + s' - s), f_0 - F(r_0 + r_1) + F(r_0 + r_1 + s' - s), h_0 - F(r_0 + r_2) + F(r_0 + r_2 + s' - s))$. We can check that for all these cases we obtain: $r'_2 = r_2, t_1 = t'_1, e'_1 = e_1, f'_1 = f_1, h'_1 = h_1$ and then $c'_0 = c_0, c'_2 = c_2, c'_4 = c_4$. The last case is Q = 2. Then

$$\langle P(s), \mathcal{CV} \rangle (F, v) = ((c_0, c_1, c_2, c_3, c_4), 3, (r_1, r_2, t_0, e_0, f_0, h_3)) \\ \langle \mathcal{S}, \mathcal{CV} \rangle (F, v) = ((c'_0, c'_1, c'_2, c'_3, c'_4), 2, (r'_1, r'_2, t'_0, e'_0, f'_0, h'_0))$$

Assume that $(r'_0, r'_1, t'_0, e'_0, f'_0, h'_0) = (r_0s' - s, r_1, t_0, e_0, f_0, h_0)$, then we obtain $r'_2 = r_2, c'_0 = c_0, c'_1 = c_1$ and $c'_3 = c_3$. Since the commitment is statistically hiding, we get that when S does not output \bot , the distribution of the output of S is statistically close to the distribution of the real transcript. \Box

Theorem 2 The 3-pass protocol is proof of zero knowledge with zero knowledge error 3/4 when the commitment scheme Com is computationally binding.

Proof. Suppose that there exists a false prover C that can answer all the questions. Then either C will compute a collision for Com or will extract a solution for (F, v). Let $((c_0, c_1, c_2, c_3, c_4), \mathcal{Q}_0, Rsp_0), ((c_0, c_1, c_2, c_3, c_4), \mathcal{Q}_1, Rsp_1), ((c_0, c_1, c_2, c_3, c_4), \mathcal{Q}_2, Rsp_2), ((c_0, c_1, c_2, c_3, c_4), \mathcal{Q}_3, Rsp_3)$, be four transcripts such that $\mathcal{Q}_i = i$ and all the responses are accepted. Consider the situation where the responses are parsed as $Rsp_0 = (r_0^{(0)}, r_1^{(0)}, t_1^{(0)}, e_1^{(0)}, f_1^{(0)}), Rsp_1 = (r_0^{(1)}, r_2^{(1)}, t_1^{(1)}, e_1^{(1)}, h_1^{(1)}), Rsp_2 = (r_1^{(2)}, r_2^{(2)}, t_1^{(2)}, e_1^{(2)}, f_1^{(2)}), Rsp_3 = (r_1^{(3)}, r_2^{(3)}, t_0, e_0, f_0, h_0).$ We obtain:

$$c_{0} = Com(r_{1}^{(2)}, r_{2}^{(2)}, v - G(t_{1}^{(2)}, r_{1}^{(2)}, r_{2}^{(2)}) - f_{1}^{(2)} - h_{1}^{(2)} + e_{1}^{(2)} -F(r_{1}^{(2)} + r_{2}^{(0)}) + F(r_{1}^{(2)}) + F(r_{2}^{(2)})) = Com(r_{1}^{(3)}, r_{2}^{(3)}, G(t_{0}, r_{1}^{(3)}, r_{2}^{(3)}) + f_{0} + h_{0} - e_{0})$$
(1)

$$c_{1} = Com(r_{1}^{(0)}, r_{0}^{(0)} - t_{1}^{(0)}, F(r_{0}^{(0)}) - e_{1}^{(0)}, F(r_{0}^{(0)} + r_{1}^{(0)}) - f_{1}^{(0)}) = Com(r_{1}^{(3)}, t_{0}, e_{0}, f_{0})) (2)$$

$$c_{2} = Com(r_{1}^{(0)}, t_{1}^{(0)}, e_{1}^{(0)}, f_{1}^{(0)}) = Com(r_{1}^{(2)}, t_{1}^{(2)}, e_{1}^{(2)}, f_{1}^{(2)})$$

$$c_{3} = Com(r_{2}^{(1)}, r_{0}^{(1)} - t_{1}^{(1)}, F(r_{0}^{(1)}) - e_{1}^{(1)}, F(r_{0}^{(1)} + r_{2}^{(1)}) - h_{1}^{(1)}) = Com(r_{2}^{(3)}, t_{0}, e_{0}, h_{0})) (4)$$

$$c_{4} = Com(r_{2}^{(1)}, t_{1}^{(1)}, e_{1}^{(1)}, h_{1}^{(1)}) = Com(r_{2}^{(2)}, t_{1}^{(2)}, e_{1}^{(2)}, h_{1}^{(2)})$$

$$(5)$$

If two tuples of the arguments of *Com* are are distinct on either of the above equations, then we have a collision for *Com*. Otherwise, these equalities give:

$$\begin{aligned} h_1^{(1)} &\stackrel{(5)}{=} h_1^{(2)}, r_1^{(0)} \stackrel{(2)}{=} r_1^{(3)} \stackrel{(1)}{=} r_1^{(2)}, t_1^{(0)} \stackrel{(3)}{=} t_1^{(1)} \stackrel{(5)}{=} t_1^{(2)}, r_0^{(0)} \stackrel{(3,4)}{=} r_0^{(1)} \end{aligned} \\ \text{and} \quad r_2^{(2)} \stackrel{(1)}{=} r_2^{(3)} \stackrel{(4)}{=} r_2^{(1)}, e_1^{(2)} \stackrel{(3)}{=} e_1^{(0)} \stackrel{(2,4)}{=} e_1^{(1)}, f_1^{(0)} \stackrel{(3)}{=} f_1^{(2)} \end{aligned}$$

So, all upper scripts are useless and from (1) we have:

$$v = G(t_1 + t_0, r_1, r_2) + f_1 + h_1 - e_1 + F(r_1 + r_2) - F(r_1) - F(r_2) + f_0 + h_0 - e_0$$

Then, from (2) and (4) we have $r_0 = t_0 + t_1$, $F(r_0) = e_0 + e_1$, $F(r_0 + r_1) = f_0 + f_1$ and $F(r_0 + r_2) = h_0 + h_1$, so if we replace these values in the previous equality, we obtain: $v = G(r_0, r_1, r_2) + F(r_0 + r_1) + F(r_0 + r_2) + F(r_1 + r_2) - F(r_0) - F(r_1) - F(r_2) = F(r_0 + r_1 + r_2)$ This means that a solution $r_0 + r_1 + r_2$ for v is extracted.

Let p_s be the probability that P^* convinces the honest verifier on s and p the probability that all the 3 transcripts are accepted. Suppose that $p_s > \frac{3}{4}$. Depending on the fact that the 4 transcripts are accepted or not, we get $p_s \leq 1 \cdot p + \frac{3}{4}(1-p)$. This implies that $p \geq 4(p_s - \frac{3}{4})$. Thus the proof of Theorem 2 is complete.

4.3 Computations in the 3-pass scheme

We give the maximum number of computations that have to be done either by the prover or by the receiver in the case of \mathbb{F}_2 . We must calculate the number of computations for F and for G. Moreover we see that F is computed at most 3 times and G is computed just one time. We only count multiplications. In \mathbb{F}_2 , we have: $x_i^3 = x_i^2 = x_i$. We can write:

$$f_{\ell}(x) = \sum_{i=1}^{n} x_i \left[\gamma_i^{\ell} + \gamma_{ii}^{\ell} + \gamma_{iii}^{\ell} + \sum_{j=i+1}^{n} x_j \left(\gamma_{ij}^{\ell} + \gamma_{ijj}^{\ell} + \sum_{k=j+1}^{n} \gamma_{ijk}^{\ell} x_k \right) \right]$$

Let M denotes the number of multiplications needed to compute F. Using the above expression for F, we obtain $M \simeq \frac{n^3}{6}m$. In the following table, we give the characteristics of the scheme ZK(3) and the values that we obtain when we

choose n = 84, m = 80, in order to have 80-bit security (cf. [2]). Moreover if we want an impersonation probability less than 2^{-30} , we need to perform at least 73 rounds. R stands for the number of rounds and C for the maximum number of computations that have to be done either by the prover or by the receiver. The values are given in Table 1.

Remark. We may need less computations. It depends on the number of non

Table	1.	ZK	(3)	Scheme
-------	----	----	-----	--------

	Formulas	Parameters for 2^{80} security

zero coefficients. This is the case for Brent equations as explain in Section 8.

4.4 5-pass scheme

Here we describe briefly a 5-pass scheme. Proofs are sketched in Appendix A.

1. The Prover picks up at random $r_0, r_1, t_0 \in \mathbb{F}_q^n$ and $e_0, f_0, h_0 \in \mathbb{F}_q^m$. Then she computes $r_2 = s - r_1 - r_0$. The Prover sends to the Verifier

$$\begin{aligned} c_0 &= Com(r_1, r_2, G(t_0, r_1, r_2) - e_0 + f_0 + h_0) \\ c_1 &= Com(r_1, t_0, e_0, f_0) \\ c_2 &= Com(r_1, t_1, e_1, f_1) \\ c_3 &= Com(r_2, t_0, e_0, h_0) \\ c_4 &= Com(r_2, t_1, e_1, h_1) \end{aligned}$$

- 2. The verifier picks $\alpha \in_R \mathbb{F}_q$ and sends α to the prover.
- 3. The prover computes:

$$(t_1, e_1 f_1, h_1) = (\alpha r_0 - t_0, \alpha F(r_0) - e_0, \alpha F(r_0 + r_1) - f_0, \alpha F(r_0 + r_2) - h_0)$$

and sends (t_1, e_1f_1, h_1) to the verifier.

4. The verifier picks $\mathcal{Q} \in_R \{0, 1, 2\}$ and sends \mathcal{Q} to the prover.

- 5. (a) If $\mathcal{Q} = 0$, then the prover sends (r_0, r_1) . The verifier checks if $c_0 = Com(r_0, r_1, \alpha r_0 t_1, \alpha F(r_0) e_1, \alpha F(r_0 + r_1) f_1)$.
 - (b) If $\mathcal{Q} = 1$, then the prover sends (r_0, r_2) . The verifier checks if $c_1 = Com(r_0, r_2, \alpha r_0 t_1, \alpha F(r_0) e_1, \alpha F(r_0 + r_2) h_1)$.
 - (c) If Q = 2, then the prover sends (r_1, r_2) . The verifier checks if $c_2 = Com(r_1, r_2, \alpha(v F(r_1 + r_2) + F(r_1) + F(r_2)) G(t_1, r_1, r_2) f_1 h_1 + e_1)$.

As for the 3-pass scheme, we have perfect correctness and the following results:

Theorem 3 The 5-pass protocol is statistically zero knowledge when the commitment scheme Com is statistically hiding.

Theorem 4 The 5-pass protocol is proof of zero knowledge with zero knowledge error 2/3 + 1/3q when the commitment scheme Com is computationally binding.

5 The $\tilde{ZK}(3)$ Scheme.

In this section, we propose another scheme inspired from [12]. The idea is to transform the cubic system into a quadratic one and the to use the scheme given in [12]. As we will see, the number of computations is smaller, but the number of communication bits is more important.

We investigate the transformation of a system with cubic equations to a system with quadratic equations. We will introduce new variables. Once we have obtained a system of equations with quadratic polynomials, we can apply the identification scheme of [12]. We will calculate the number of multiplications in this case. In our system, we have $F(x) = (f_1(x), f_2(x), \ldots, f_m(x))$ where $\forall \ell, 1 \leq \ell \leq m$,

and $x = (x_1, \ldots, x_n)$. We introduce the new variables $\forall i, j, 1 \leq i \leq j \leq n, X_{ij} = x_i x_j$. The number of new variables is $\frac{n(n-1)}{2}$, if q = 2, and $\frac{n(n+1)}{2}$, if $q \neq 2$. In our new system, we have

$$\tilde{F} = (\tilde{f}_1, \dots, \tilde{f}_m, (\tilde{f}_{ij})_{1 \le i \le j \le n})$$

where for $\tilde{x} = (x_1, \ldots, x_n, (X_{ij})_{1 \le i \le j \le n})$ and $1 \le \ell \le m$,

$$f_{\ell}(\tilde{x}) = \sum_{1 \leq i \leq j \leq k \leq n} \gamma_{ijk}^{\ell} X_{ij} x_k + \sum_{1 \leq i \leq j \leq n} \gamma_{ij}^{\ell} X_{ij} + \sum_{1 \leq i \leq n} \gamma_i^{\ell} x_i$$

and for $1 \leq i \leq j \leq n$, $f_{ij}(\tilde{x}) = X_{ij} - x_i x_j$. Here the number of variables is $\tilde{n} \simeq n + \frac{n^2}{2}$ and the number of equations is $\tilde{m} = m + \frac{n^2}{2}$. As before, Mdenotes the number of multiplications needed to compute F. \tilde{M} denotes the number of multiplications for the computation of \tilde{F} . We choose q = 2. Then $\tilde{M} = M + \frac{n(n-1)}{2}$. Thus $\tilde{M} \simeq M \simeq \frac{n^3}{6}$. \tilde{C} stands for the maximum number of computations that have to be done either by the prover or by the receiver. If \tilde{R} denotes the number of rounds performed in order to have an impersonation probability less than 2^{-30} , then $\tilde{R} = 52$ (cf. [12]). The following table gives the characteristics of the $\tilde{ZK}(3)$ Scheme and the values we get when n = 84 and m = 80.

Table 2. $\tilde{ZK}(3)$ Scheme

	Formulas	Parameters for 2^{80} security
Public key (bit)	\tilde{m}	3483
Secret key (bit)	n	84
M	$\frac{n^3}{6} \times m$	7902720
Communication (bit)	$(2 \times 160 + 2 + 2\tilde{n} + \tilde{m}) \times \tilde{R}$	560508
Number of multiplications	$\tilde{C} = 3\tilde{M}\tilde{R}$	2^{31}

6 ZK(d) and ZK(d) Schemes for any d

6.1 The ZK(d) Scheme

We will design a 3-pass scheme We consider the following function of degree d from \mathbb{F}_q^n to \mathbb{F}_q^m :

$$F(x) = (f_1(x), f_2(x), \dots, f_m(x))$$

where $\forall \ell, 1 \leq \ell \leq m$,

$$f_{\ell}(x) = \sum_{1 \le i_i \le \dots \le i_d \le n} \gamma_{i_1 \dots i_d}^{\ell} x_{i_1} x_{i_2} \dots x_{i_d} +$$

$$\sum_{1 \le i_i \le \dots \le i_{d-1} \le n} \gamma_{i_1 \dots i_{d-1}}^{\ell} x_{i_1} x_{i_2} \dots x_{i_{d-1}} + \dots + \sum_{1 \le i_i \le i_2 \le n} \gamma_{i_1 i_2}^{\ell} x_{i_1} x_{i_2} + \sum_{1 \le i_i \le n} \gamma_{i_1}^{\ell} x_{i_1} x_{i_2} + \sum_{i_i \le n} \gamma_{i_i} x_{i_i} x_{i_i} x_{i_i} x_{i_i} + \sum_{i_i \le n} \gamma_{i_i} x_{i_i} x_{i_i} x_{i_i} x_{i_i} + \sum_{i_i \le n} \gamma_{i_i} x_{i_i} x_$$

and $x = (x_1, \ldots, x_n)$. We omit the constant term. Let

$$G(r_0, r_1, \dots, r_{d-1}) = \sum_{i=1}^d (-1)^{d-i} \sum_{\substack{S \subset \{0, \dots, d-1\} \\ |S|=i}} F(\sum_{j \in S} r_j)$$

Then G is d-linear.

The problem is: Given F and $v \in \mathbb{F}_q^m$ find $s \in \mathbb{F}_q^n$ such that F(s) = v. The public key is (F, v). The secret is s such that F(s) = v.

1. The Prover picks up at random $r_0, r_1, \ldots, r_{d-2}, t_0 \in_R \mathbb{F}_q^n$, $f_0 \in_R \mathbb{F}_q^m$, and $\forall p, 1 \leq p \leq d-2, \forall i_1, \ldots i_p, 1 \leq i_1 < i_2 < \ldots i_p \leq d-1, f_0^{i_1 \ldots i_p}, \in_R \mathbb{F}_q^m$. Then she computes

$$r_{d-1} = s - \sum_{i=1}^{d-2} r_i$$

$$t_1 = r_0 - t_0$$

$$f_1 = F(r_0) - f_0$$

and

$$\begin{aligned} \forall p, \ 1 \le p \le d-2, \ \forall i_1, \dots i_p, \ 1 \le i_1 < i_2 < \dots i_p \le d-1 \\ f_1^{i_1 \dots i_p} = F(r_0 + r_{i_1} + \dots + r_{i_p}) - f_0^{i_1 \dots i_p} \end{aligned}$$

Then the Prover sends to the Verifier

$$c_{0} \leftarrow Com\left(r_{1}, \dots, r_{d-1}, G(t_{0}, r_{1}, \dots, r_{d-1}) + \sum_{p=1}^{d-2} (-1)^{d-p} \sum_{i_{1} \leq i_{1} < \dots < i_{p} \leq d-1} f_{0}^{i_{1} \dots i_{p}} + (-1)^{d} f_{0}\right)$$

$$\forall i, 1 \leq i \leq d-1$$

$$c_{2i-1} \leftarrow Com\left(r_{1}, \dots, r_{i-1}, r_{i+1}, \dots, r_{d-1}, t_{0}, f_{0}, d_{0}, d_$$

The verifier chooses a query $Q \in_R \{0, 1, \ldots, d\}$ and sends Q to the prover.

2. (a) If $\mathcal{Q} = 0$, then the Prover sends $(r_1, r_2, \ldots, r_{d-1}, t_0, f_0, \forall p, 1 \le p \le d-2, \forall i_1, \ldots i_p, 1 \le i_1 < i_2 < \ldots i_p \le d-1, f_0^{i_1 \ldots i_p}$. The Verifier checks if

$$c_0 = Com \Big(r_1, \dots, r_{d-1}, G(t_0, r_1, \dots, r_{d-1}) + \sum_{p=1}^{d-2} (-1)^{d-p} \Big)$$
$$\sum_{1 \le i_1 < \dots < i_p \le d-1} f_0^{i_1 \dots i_p} + (-1)^d f_0 \Big)$$

and $\forall i, 1 \leq i \leq d-1$,

$$c_{2i-1} = Com \Big(r_1, \dots, r_{i-1}, r_{i+1}, \dots, r_{d-1}, t_0, f_0, \\ \forall p, \ 1 \le p \le d-2, \ \forall i_1, \dots, i_p, \ 1 \le i_1 < i_2 < \dots, i_p \le d-1, \\ \text{such that } \forall j, \ i_j \ne i, \ f_0^{i_1 \dots i_p} \Big)$$

(b) If Q = d, then the Prover sends $(r_1, r_2, \dots, r_{d-1}, t_1, f_1, \forall p, 1 \le p \le d-2, \forall i_1, \dots, i_p, 1 \le i_1 < i_2 < \dots i_p \le d-1, f_1^{i_1 \dots i_p}). \forall i, 1 \le i \le d-1,$ The Verifier checks if

$$c_0 = Com \Big(r_1, \dots, r_{d-1}, v - G(t_1, r_1, \dots, r_{d-1}) - \sum_{p=1}^{d-2} (-1)^{d-p} \Big)$$

$$\sum_{\substack{1 \le i_1 < \dots < i_p \le d-1 \\ (-1)^d f_1 + \sum_{i=1}^d (-1)^{d-i} \sum_{\substack{S \subset \{1,\dots,d-1\} \\ |S|=i}} F(\sum_{j \in S} r_j)} F(\sum_{j \in S} r_j) \Big)$$

and $\forall i, 1 \leq i \leq d-1$,

$$c_{2i} = Com \Big(r_1, \dots, r_{i-1}, r_{i+1}, \dots, r_{d-1}, t_1, f_1, \\ \forall p, \ 1 \le p \le d-2, \ \forall i_1, \dots, i_p, \ 1 \le i_1 < i_2 < \dots i_p \le d-1, \ \text{such} \\ \text{that} \ \forall j, \ i_j \ne i, \ f_1^{i_1 \dots i_p} \Big)$$

(c) if $\mathcal{Q} = i$, then the prover sends $(r_0, r_1, \ldots, r_{i-1}, r_{i+1}, \ldots, r_{d-1}, t_1, f_1, \forall p, 1 \leq p \leq d-2, \forall i_1, \ldots i_p, 1 \leq i_1 < i_2 < \ldots i_p \leq d-1,$ such that $\forall j, i_j \neq i, f_1^{i_1 \ldots i_p}$) The Verifier checks if

$$c_{2i-1} = Com \Big(r_1, \dots, r_{i-1}, r_{i+1}, \dots, r_{d-1}, r_0 - t_1, F(r_0) - f_1, \\ \forall p, \ 1 \le p \le d-2, \ \forall i_1, \dots, i_p, \ 1 \le i_1 < i_2 < \dots, i_p \le d-1, \\ \text{such that } \forall j, \ i_j \ne i, \ F(r_0 + r_{i_1} + \dots + r_{i_p}) - f_1^{i_1 \dots i_p} \Big)$$

and

$$c_{2i} = Com(r_1, \dots, r_{i-1}, r_{i+1}, \dots, r_{d-1}, t_1, f_1, \\ \forall p, \ 1 \le p \le d-2, \ \forall i_1, \dots, i_p, \ 1 \le i_1 < i_2 < \dots i_p \le d-1, \\ \text{such that } \forall j, \ i_j \ne i, \ f_1^{i_1 \dots i_p})$$

As for the the case d = 3, we have perfect correctness and the following results (see Appendix B for details):

Theorem 5 The 3-pass protocol ZK(d) is statistically zero knowledge when the commitment scheme Com is statistically hiding.

Theorem 6 The 3-pass protocol is proof of zero knowledge with zero knowledge error $\frac{d}{d+1}$ when the commitment scheme Com is computationally binding.

Remark. As for the case d = 3, it is possible to design a 5-pass scheme.

6.2 The $\tilde{ZK}(d)$ Scheme

Here we explain how it is possible to design the $Z\tilde{K}(d)$ Scheme. Again there are two functions F and \tilde{F} . If M (resp. \tilde{M}) denotes the number of computations for F (resp. \tilde{F}), then $M \simeq n^d/d!$ and $\tilde{M} \simeq \frac{n^d}{d!} + n^{\lceil \frac{d}{2} \rceil} / \lceil \frac{d}{2} \rceil! \simeq M$. For ZK(d), there are n variables and m equations. For $Z\tilde{K}(d)$, there are $\tilde{n} \simeq n + n^{\lceil \frac{d}{2} \rceil} / \lceil \frac{d}{2} \rceil!$ variables and $\tilde{m} \simeq m + n^{\lceil \frac{d}{2} \rceil} / \lceil \frac{d}{2} \rceil!$ equations. There are more multiplications in ZK(d) and more communication bits in $Z\tilde{K}(d)$. The values for both schemes are given in Table 3. Here we have an impersonation probability less than 2^{-30} .

	ZK(d) scheme	$\tilde{ZK}(d)$ scheme
Public key (bits)	m	$\tilde{m} \simeq m + n^{\left\lceil \frac{d}{2} \right\rceil} / \left\lceil \frac{d}{2} \right\rceil!$
Secret key (bits)	n	n
M	$rac{n^d}{d!} imes m$	$\frac{n^d}{d!} imes m$
Rounds	$R = \left\lceil \frac{30\ln(2)}{\ln(1+1/d)} \right\rceil$	$\tilde{R} = 52$
Number of	$\left(5dn + \left\lceil \frac{\ln d}{2} \right\rceil + 2^{d-1} - 1\right) \cdot R$	
Communication	or	$\left (322+2n+m+3n^{\lceil \frac{d}{2} \rceil}/\lceil \frac{d}{2} \rceil!) \cdot \tilde{R} \right $
bits	$(3dn + \lceil \frac{\ln d}{2} \rceil + 2^d - 2) \cdot R$	
Multiplications	$C = 9(2^{d-1} - 1 + d!)MR$	$ ilde{C} = 3 ilde{M} ilde{R}$

Table 3. ZK(d) and $\tilde{ZK}(d)$ Schemes

6.3 Relations for sparse systems

In the previous computations, we have supposed that we have the maximum number of coefficients. Then we obtained that in both cases, $M \simeq \tilde{M} \simeq \frac{n^d}{d!}$. Then the total number of multiplications is a function of M or \tilde{M} and the number of rounds. For sparse systems, M or \tilde{M} will be smaller but we will still have the same relations between C, M and R (and similarly \tilde{C} , \tilde{M} and \tilde{R}). Here again, we can see that there are more variables and more communications bits in the $\tilde{ZK}(d)$ schemes and more computations in the ZK(d) schemes.

7 Relations between the number of computations and the number of coefficients

We begin with the ZK(d) scheme. We have:

$$f_{\ell}((x_1, x_2, \dots, x_n)) = \sum_{(i_1, \dots, i_d) \in S_d^{\ell}} \gamma_{i_1 \dots i_d}^{\ell} x_{i_1} x_{i_2} \dots x_{i_d} + \sum_{i_i, \dots, i_{d-1} \in S_{d-1}^{\ell}} \gamma_{i_1 \dots i_{d-1}}^{\ell} x_{i_1} x_{i_2} \dots x_{i_{d-1}} + \dots + \sum_{i_i, i_2 \in S_2^{\ell}} \gamma_{i_1 i_2}^{\ell} x_{i_1} x_{i_2} + \sum_{i_i \in S_2^{\ell}} \gamma_{i_1}^{\ell} x_{i_1}$$

The number of multiplications for f_{ℓ} is given by

$$d|S_d^{\ell}| + (d-1)|S_{d-1}^{\ell}| + (d-2)|S_{d-2}^{\ell}| + \dots + 2|S_2^{\ell}| + |S_1^{\ell}|$$

and for F the number M of multiplications is

$$M = \sum_{\ell=1}^{m} \left[d|S_d^{\ell}| + (d-1)|S_{d-1}^{\ell}| + (d-2)|S_{d-2}^{\ell}| + \dots + 2|S_2^{\ell}| + |S_1^{\ell}| \right]$$

Moreover, F is computed at most $2^{d-1} - 1$ times during the process. For g_l we have $(d!(d-1)+1)|S_d^{\ell}|$ multiplications and for G, $\sum_{\ell=1}^m (d!(d-1)+1)|S_d^{\ell}|$ multiplications and G is computed one time. Finally, for one round, the number of multiplications is given by

$$\left(\sum_{\ell=1}^{m} \left[\left(d(2^{d-1}-1) + d!(d-1) + 1 \right) |S_{d}^{\ell}| + (d-1) |S_{d-1}^{\ell}| + (d-2) |S_{d-2}^{\ell}| + \dots + 2|S_{2}^{\ell}| + |S_{1}^{\ell}| \right] \right) \quad (\sharp)$$

and then we have to multiply by the number of rounds R to get C. For the $\tilde{Z}K(d)$ scheme, we have $\tilde{M} = M + n^{\lceil \frac{d}{2} \rceil} / \lceil \frac{d}{2} \rceil!$. Then $\tilde{C} = 3\tilde{M}\tilde{R}$.

8 The particular case of Brent equations

In this section, we introduce the Brent equations. Suppose we want to multiply two $N \times N$ matrices. The naive method will use N^2 multiplications. In fact for N = 2, Strassen's algorithm ([16]) requires 7 multiplications instead of 8 multiplications and Laderman showed that when N = 3 it is possible to use 23 multiplications instead of $3^3 = 27$ ([6]). For N = 2, 7 is the least number we can obtain. For N = 3, it is not known if 23 is the least number in the non-commutative case. In [1], it is shown that obtaining the product of two matrices $N \times N$ can be done using s multiplications is equivalent to solve the following system of cubic

equations: $\sum_{k=1}^{s} \gamma_{ijk} \alpha_{abk} \beta_{cdk} = \delta_{bc} \delta_{ia} \delta_{jd} \qquad a, b, c, d, i, j \in \{1, 2, \dots, n\}$ Here we have $n = 3sN^2$, $m = N^6$. If we use formula (\sharp), we obtain that the

Here we have $n = 3sN^2$, $m = N^6$. If we use formula (\sharp), we obtain that the number of multiplications is $22 \times s \times N^6$ if we use the ZK(3) scheme. It is also interesting to design an authentication public key cryptographic scheme as close as possible to Brent equations. In order to do this, we choose a system similar to Brent equations but for which we know a particular solution. It is possible to proceed as follows:

- 1. We consider the finite field $\mathbb{Z}/2\mathbb{Z}$
- 2. We take the Brent equations with s = 22 in order obtain an open problem in the non-commutative case
- 3. We pick randomly variables α, β, γ in $\mathbb{Z}/2\mathbb{Z}$
- 4. We deduce the corresponding constants
- 5. We then use either ZK(3) or ZK(3) to have a zero-knowledge protocol.

9 Morphisms of polynomials and systems of cubic equations

9.1 The MP Problem

The IP problem (Isomorphism of Polynomials) has been used to construct pubic key schemes (cf [9]). On one hand, this is not a NP-complete problem since it admits an Arthur-Merlin game when the answer is yes and when the answer is no). On the other hand, the MP problem(morphisms of polynomials) where matrices are not supposed to be invertible is proved to be NP-complete ([3, 10]) and thus is much more difficult. So it is interesting to design a public key authentication scheme based on MP. We explain briefly below how it is possible to construct such a scheme by transforming MP very efficiently into a system of equations of degree 3 and then applying our ZK(3) or $\tilde{Z}K(3)$ protocols.

9.2 From MP to polynomials of degree 3

We consider the two following systems:

$$(\mathcal{A}) \quad c_k = \sum_{1 \le i \le n, \ 1 \le j \le n} \gamma_{ij}^k a_i a_j + \sum_{i=1}^n \mu_i^k a_i, \quad 1 \le k \le u$$
$$(\mathcal{B}) \quad z_t = \sum_{1 \le i \le p, \ 1 \le j \le p} \alpha_{ij}^t x_i x_j + \sum_{i=1}^p \beta_i^t x_i, \quad 1 \le t \le v$$

We want to find 2 matrices $M = (m_{rs})_{\substack{1 \le r \le v \\ 1 \le s \le u}}$ and $H = (h_{df})_{\substack{1 \le d \le n \\ 1 \le f \le p}}$ such that

$$M\begin{pmatrix}c_1\\\vdots\\c_u\end{pmatrix} = \begin{pmatrix}z_1\\\vdots\\z_v\end{pmatrix} \quad \text{and} \quad H\begin{pmatrix}x_1\\\vdots\\x_p\end{pmatrix} = \begin{pmatrix}a_1\\\vdots\\a_n\end{pmatrix}$$

For all $t, 1 \le t \le v$, on one hand, we have:

other hand, we have: $z_t = \sum_{\substack{1 \le i \le p \\ 1 \le j \le p}} \alpha_{ij}^t x_i x_j + \sum_{i=1} \beta_i^t x_i$. This gives $\forall t \ 1 \le t \le t$

$$v, \ \forall f, 1 \leq f \leq p, \ \forall b, 1 \leq b \leq p, \ \alpha_{fb}^t + \beta_f^t = \sum_{\substack{s=1 \ 1 \leq i \leq n \\ 1 \leq j \leq n}}^u \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{s=1}^u \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{s=1}^u \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{s=1}^u \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{s=1}^u \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{s=1}^u \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{s=1}^u \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{s=1}^u \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{s=1}^u \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{jb} + \beta_f^t = \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{if} h_{jb} + \beta_f^t = \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{if} h_{jb} + \beta_f^t = \sum_{\substack{1 \leq i \leq n \\ 1 \leq j \leq n}} \gamma_{ij}^s m_{ts} h_{if} h_{$$

 $\sum_{s=1}^{n} \sum_{i=1}^{n} \mu_{i}^{s} m_{ts} h_{if}.$ Thus we obtain vp^{2} cubic equations and np + vu unknowns.

10 Conclusion

In [12], a very efficient zero-knowledge proof based on the MQ problem (multivariate quadratic polynomials) is given. In this paper we proved that this construction can be generalized to polynomials of degree d for any $d \ge 3$. We studied several constructions and we presented here the two most efficient ones denoted by ZK(d) and $\tilde{Z}K(d)$. ZK(d) is quasi optimal in term of communication bits and $\tilde{Z}K(d)$ is quasi optimal in term of number of computations. This result is true for dense or sparse systems. We also presented two important specific problems (Brent equations and morphisms of polynomials) that can be transformed into efficient public key schemes using ZK(d) and $\tilde{Z}K(d)$.

A 5-pass scheme for ZK(3)

In this appendix, we give sketches of proof for the 5-passes scheme.

1. The Prover picks up at random $r_0, r_1, t_0 \in \mathbb{F}_q^n$ and $e_0, f_0, h_0 \in \mathbb{F}_q^m$. Then she computes $r_2 = s - r_1 - r_0$. The Prover sends to the Verifier

 $c_{0} = Com(r_{1}, r_{2}, G(t_{0}, r_{1}, r_{2}) - e_{0} + f_{0} + h_{0})$ $c_{1} = Com(r_{1}, t_{0}, e_{0}, f_{0})$ $c_{2} = Com(r_{1}, t_{1}, e_{1}, f_{1})$ $c_{3} = Com(r_{2}, t_{0}, e_{0}, h_{0})$ $c_{4} = Com(r_{2}, t_{1}, e_{1}, h_{1})$

- 2. The verifier picks $\alpha \in_R \mathbb{F}_q$ and sends α to the prover.
- 3. The prover computes:

$$(t_1, e_1 f_1, h_1) = (\alpha r_0 - t_0, \alpha F(r_0) - e_0, \alpha F(r_0 + r_1) - f_0, \alpha F(r_0 + r_2) - h_0)$$

and sends (t_1, e_1f_1, h_1) to the verifier.

- 4. The verifier picks $\mathcal{Q} \in_R \{0, 1, 2\}$ and sends \mathcal{Q} to the prover.
- 5. (a) If $\mathcal{Q} = 0$, then the prover sends (r_0, r_1) . The verifier checks if $c_0 = Com(r_0, r_1, \alpha r_0 t_1, \alpha F(r_0) e_1, \alpha F(r_0 + r_1) f_1)$.

- (b) If $\mathcal{Q} = 1$, then the prover sends (r_0, r_2) . The verifier checks if $c_1 = Com(r_0, r_2, \alpha r_0 t_1, \alpha F(r_0) e_1, \alpha F(r_0 + r_2) h_1)$.
- (c) If Q = 2, then the prover sends (r_1, r_2) . The verifier checks if $c_2 = Com(r_1, r_2, \alpha(v F(r_1 + r_2) + F(r_1) + F(r_2)) G(t_1, r_1, r_2) f_1 h_1 + e_1)$.

As for the 3-pass scheme, we have perfect correctness and the following results(Proofs are sketched in Appendix A:

Theorem 7 The 5-pass protocol is statistically zero knowledge when the commitment scheme Com is statistically hiding.

Proof sketch. Let S be a simulator which takes F and v without knowing s, and interacts with a cheating verifier \mathcal{CV} . We show that the simulator can impersonate the honest prover with probability 2/3. The simulator randomly chooses a value $Ch^* \in_R \{0, 1, 2\}$ and vectors $s', r'_0, r'_1, t'_0 \in_R \mathbb{F}_q^n$ and $e'_0, f'_0, h'_0 \in_R \mathbb{F}_q^m$, where Ch^* is a prediction what value the cheating verifier \mathcal{CV} will not choose. Then it computes

$$\begin{aligned} r'_2 \leftarrow s' - (r'_0 + r'_1) \\ c'_0 \leftarrow Com(r'_0, r'_1, t'_0, e'_0, f'_0) \\ c'_1 \leftarrow Com(r'_0, r'_2, t'_0, e'_0, h'_0) \\ c'_2 \leftarrow Com(r'_1, r'_2, G(t'_0, r'_1, r'_2) + f'_0 + h'_0 - e'_0) \end{aligned}$$

and sends (c'_0, c'_1, c'_2) to \mathcal{CV} . Then receiving a challenge α from \mathcal{CV} , it computes:

$$t'_1 = \alpha r'_0 - t'_0$$

 $e'_1 = \alpha F(r'_0) - e'_0$

Now

if $Ch^* = 0$ it sets $f'_1 = \alpha(v - F(s')) + F(r'_0 + r'_1) - f'_0$, else $f'_1 = \alpha F(r'_0 + r'_1) - f'_0$ if $Ch^* = 1$ it sets $h'_1 = \alpha(v - F(s')) + F(r'_0 + r'_2) - h'_0$, else $f'_1 = \alpha F(r'_0 + r'_2) - h'_0$ Then it sends $(t'_1, e'_1 f'_1, h'_1)$ to \mathcal{CV}

Due to the statistically hiding property of Com, a challenge Ch from \mathcal{CV} is different from Ch^* with probability 2/3. If $Ch \neq Ch^*$, then (r'_0, r'_1) , (r'_0, r'_2) , and (r'_1, r'_2) are accepted responses to Ch = 0, 1 and 2 respectively.

Theorem 8 The 5-pass protocol is proof of zero knowledge with zero knowledge error 2/3+1/3q when the commitment scheme Com is computationally binding.

Proof sketch. Let $((c_1, c_1, c_2), \alpha_i, (\tilde{t}_1^{(i)}, \tilde{e}_1^{(i)}, \tilde{f}_1^{(i)}, \tilde{h}_1^{(i)}), Ch_j, Rsp^{(i,j)})$ be six transcripts for $i \in \{0, 1\}$ and $j \in \{0, 1, 2\}$ such that

 $Dec(F, v, ((c_1, c_1, c_2), \alpha_i, (\tilde{t}_1^{(i)}, \tilde{e}_1^{(i)}, \tilde{f}_1^{(i)}), Ch_j, Rsp^{(i,j)}p) = 1, \alpha_0 \neq \alpha_1$, and $Ch_j = j$. Then, by using the six transcripts, we show that we are able either to break the binding property of *Com* or extract a solution for v. Consider the situation where the responses are parsed as

$$Rsp^{(0,0)} = (\tilde{r}_0^{(0)}, \tilde{r}_1^{(0)})$$

$$\begin{aligned} Rsp^{(0,1)} &= (\tilde{r}_0^{(0)}, \tilde{r}_2^{(0)}) \\ Rsp^{(0,2)} &= (\tilde{r}_1^{(0)}, \tilde{r}_2^{(0)}) \\ Rsp^{(1,0)} &= (\tilde{r}_0^{(1)}, \tilde{r}_1^{(1)}) \\ Rsp^{(1,1)} &= (\tilde{r}_0^{(1)}, \tilde{r}_2^{(1)}) \\ Rsp^{(1,2)} &= (\tilde{r}_1^{(1)}, \tilde{r}_2^{(1)}) \end{aligned}$$

Then we have:

$$c_{0} = Com(\tilde{r}_{0}^{(0)}, \tilde{r}_{1}^{(0)}, \alpha_{0}\tilde{r}_{0}^{(0)} - \tilde{t}_{1}^{(0)}, \alpha_{0}F(\tilde{r}_{0}^{(0)}) - \tilde{e}_{1}^{(0)}, \alpha_{0}F(\tilde{r}_{0}^{(0)} + \tilde{r}_{1}^{(0)}) - \tilde{f}_{1}^{(0)})$$

$$= Com(\tilde{r}_{0}^{(1)}, \tilde{r}_{1}^{(1)}, \alpha_{1}\tilde{r}_{0}^{(1)} - \tilde{t}_{1}^{(1)}, \alpha_{1}F(\tilde{r}_{0}^{(1)}) - \tilde{e}_{1}^{(1)}, \alpha_{1}F(\tilde{r}_{0}^{(1)} + \tilde{r}_{1}^{(1)}) - \tilde{f}_{1}^{(1)})$$
(6)

$$c_{1} = Com(\tilde{r}_{0}^{(0)}, \tilde{r}_{2}^{(0)}, \alpha_{0}\tilde{r}_{0}^{(0)} - \tilde{t}_{1}^{(0)}, \alpha_{0}F(\tilde{r}_{0}^{(0)}) - \tilde{e}_{1}^{(0)}, \alpha_{0}F(\tilde{r}_{0}^{(0)} + \tilde{r}_{2}^{(0)}) - \tilde{h}_{1}^{(0)})$$

$$= Com(\tilde{r}_{0}^{(1)}, \tilde{r}_{2}^{(1)}, \alpha_{1}\tilde{r}_{0}^{(1)} - \tilde{t}_{1}^{(1)}, \alpha_{1}F(\tilde{r}_{0}^{(1)}) - \tilde{e}_{1}^{(1)}, \alpha_{1}F(\tilde{r}_{0}^{(1)} + \tilde{r}_{2}^{(1)}) - \tilde{h}_{1}^{(1)})$$
(7)

$$c_{2} = Com(\tilde{r}_{1}^{(0)}, \tilde{r}_{2}^{(0)}, \alpha_{0}(v - F(\tilde{r}_{1}^{(0)} + \tilde{r}_{2}^{(0)}) + F(\tilde{r}_{1}^{(0)}) + F(\tilde{r}_{2}^{(0)})) - G(\tilde{t}_{1}^{(0)}, \tilde{r}_{1}^{(0)}, \tilde{r}_{2}^{(0)}) -\tilde{f}_{1}^{(0)} - \tilde{h}_{1}^{(0)} + \tilde{e}_{1}^{(0)}) = Com(\tilde{r}_{1}^{(1)}, \tilde{r}_{2}^{(1)}, \alpha_{1}(v - F(\tilde{r}_{1}^{(1)} + \tilde{r}_{2}^{(1)}) + F(\tilde{r}_{1}^{(1)}) + F(\tilde{r}_{2}^{(1)})) - G(\tilde{t}_{1}^{(1)}, \tilde{r}_{1}^{(1)}, \tilde{r}_{2}^{(1)}) -\tilde{f}_{1}^{(1)} - \tilde{h}_{1}^{(1)} + \tilde{e}_{1}^{(1)})$$
(8)

If two tuples of the arguments of Com are are distinct on either of the above equations, the binding property of Com is broken. Otherwise, (6) gives:

$$\tilde{r}_0^{(0)} = \tilde{r}_0^{(1)}, \ \tilde{r}_1^{(0)} = \tilde{r}_1^{(1)}$$

This implies:

$$(\alpha_0 - \alpha_1)\tilde{r}_0^{(0)} = -\tilde{t}_1^{(1)} + \tilde{t}_1^{(0)}$$
$$(\alpha_0 - \alpha_1)\tilde{F}(r_0^{(0)}) = -\tilde{e}_1^{(1)} + \tilde{e}_1^{(0)}$$
$$(\alpha_0 - \alpha_1)\tilde{F}(r_0^{(0)} + r_1^{(0)}) = -\tilde{f}_1^{(1)} + \tilde{f}_1^{(0)}$$

If we use (7), we obtain two more equations:

$$\tilde{r}_2^{(0)} = \tilde{r}_2^{(1)}$$
 and $(\alpha_0 - \alpha_1)\tilde{F}(r_0^{(0)} + r_2^{(0)}) = -\tilde{h}_1^{(1)} + \tilde{h}_1^{(0)}$

Now (8) gives

$$\alpha_0(v - F(\tilde{r}_1^{(0)} + \tilde{r}_2^{(0)}) + F(\tilde{r}_1^{(0)}) + F(\tilde{r}_2^{(0)})) - G(\tilde{t}_1^{(0)}, \tilde{r}_1^{(0)}, \tilde{r}_2^{(0)}) - \tilde{f}_1^{(0)} - \tilde{h}_1^{(0)} + \tilde{e}_1^{(0)} = \alpha_1(v - F(\tilde{r}_1^{(1)} + \tilde{r}_2^{(1)}) + F(\tilde{r}_1^{(1)}) + F(\tilde{r}_2^{(1)})) - G(\tilde{t}_1^{(1)}, \tilde{r}_1^{(1)}, \tilde{r}_2^{(1)}) - \tilde{f}_1^{(1)} - \tilde{h}_1^{(1)} + \tilde{e}_1^{(1)})$$

This implies that

$$(\alpha_0 - \alpha_1)v = (\alpha_0 - \alpha_1) \Big[F(\tilde{r}_1^{(0)} + \tilde{r}_2^{(0)}) - F(\tilde{r}_1^{(0)}) - F(\tilde{r}_2^{(0)}) + G(\tilde{r}_0^{(0)}, \tilde{r}_1^{(0)}, \tilde{r}_2^{(0)}) \\ + F(\tilde{r}_0^{(0)} + \tilde{r}_1^{(0)}) + F(\tilde{r}_0^{(0)} + \tilde{r}_2^{(0)}) - F(\tilde{r}_0^{(0)}) \Big]$$

Thus we obtain $v = F(\tilde{r}_0^{(0)} + \tilde{r}_1^{(0)} + \tilde{r}_2^{(0)})$. This means that a solution $\tilde{r}_0^{(0)} + \tilde{r}_1^{(0)} + \tilde{r}_2^{(0)}$ for v is extracted.

B Proofs for the ZK(d) Scheme

Theorem 9 The 3-pass protocol is statistically zero knowledge when the commitment scheme Com is statistically hiding.

Proof sketch. Let S be a simulator which takes F and v without knowing s, and interacts with a cheating verifier \mathcal{CV} . We show that the simulator can impersonate the honest prover with probability $\frac{d}{d+1}$. The simulator randomly chooses a value $Ch^* \in_R \{0, 1, \ldots, d\}$ and vectors $s', r'_0, r'_1, \ldots, r'_{d-2}, t'_0 \in_R \mathbb{F}_q^n$, $f'_0 \in_R \mathbb{F}_q^m$, and $\forall p, 1 \leq p \leq d-2$, $\forall i_1, \ldots i_p$, $1 \leq i_1 < i_2 < \ldots i_p \leq d-1$, $f_0^{i_1 \ldots i_p}$, $\in_R \mathbb{F}_q^m$, where Ch^* is a prediction what value the cheating verifier \mathcal{CV} will not choose. Then it computes

$$\begin{aligned} r'_{d-1} \leftarrow s' - \sum_{i=1}^{d-2} r'_i \\ t'_1 \leftarrow r'_0 - t'_0 \\ f'_1 \leftarrow F(r'_0) - f'_0 \\ \forall p, \ 1 \le p \le d-2, \ \forall i_1, \dots i_p, \ 1 \le i_1 < i_2 < \dots i_p \le d-1, \\ f_1^{'i_1 \dots i_p} \leftarrow F(r'_0 + r'_{i_1} + \dots + r'_{i_p}) - f_0^{'i_1 \dots i_p} \end{aligned}$$

Moreover it sets:

$$\begin{split} & \text{1. If } Ch^* = 0, \\ & c_0' = v - G(t_1', r_1', \dots, r_{d-1}') - \sum_{p=1}^{d-2} (-1)^{d-p} \sum_{1 \leq i_1 < \dots < i_p \leq d-1} f_1^{'i_1 \dots i_p} - \\ & (-1)^d f_1' \sum_{i=1}^d (-1)^{d-i} \sum_{s \in \{1, \dots, d-1\}} F(\sum_{j \in S} r_j'), \\ & \text{else } c_0 = G(t_0', r_1', \dots, r_{d-1}') + \sum_{p=1}^{d-2} (-1)^{d-p} \sum_{1 \leq i_1 < \dots < i_p \leq d-1} f_0^{'i_1 \dots i_p} \\ & + (-1)^d f_0' \\ & \text{2. If } Ch^* = i, 1 \leq i \leq d-1, f_1^{'12 \dots (i-1)(i+1) \dots (d-1)} = \\ & v - F(s') + F(r_0' + r_1 + \dots + r_{i-1}' + r_{i+1} + \dots + r_{d-1}') \\ & - f_0^{'12 \dots (i-1)(i+1) \dots (d-1)}, \\ & \text{else } f_1^{'12 \dots (i-1)(i+1) \dots (d-1)} = F(r_0' + r_1 + \dots + r_{i-1}' + r_{i+1} + \dots + r_{d-1}') \\ & - f_0^{'12 \dots (i-1)(i+1) \dots (d-1)}, \end{split}$$

It also computes:

$$\begin{aligned} \forall i, \ 1 \leq i \leq d-1 \\ c'_{2i-1} \leftarrow Com\Big(r'_1, \dots, r'_{i-1}, r'_{i+1}, \dots, r'_{d-1}, t'_0, f'_0, \\ \forall p, \ 1 \leq p \leq d-2, \ \forall i_1, \dots i_p, \ 1 \leq i_1 < i_2 < \dots i_p \leq d-1, \\ \text{ such that } \forall j, \ i_j \neq i, \ f_0^{'i_1 \dots i_p} \Big) \\ c_{2i} \leftarrow Com\Big(r'_1, \dots, r'_{i-1}, r'_{i+1}, \dots, r'_{d-1}, t'_1, f'_1, \\ \forall p, \ 1 \leq p \leq d-2, \ \forall i_1, \dots i_p, \ 1 \leq i_1 < i_2 < \dots i_p \leq d-1, \\ \text{ such that } \forall j \ i_j \neq i, \ f_1^{'i_1 \dots i_p} \Big) \end{aligned}$$

and sends $c'_0, c'_1, c'_2, \ldots, c'_{2d-2}$ to $t\mathcal{CV}$.

Due to the statistically hiding property of Com, a challenge Ch from \mathcal{CV} is different from Ch^* with probability $\frac{d}{d+1}$. If $Ch \neq Ch^*$, then $(r_1, r_2, \ldots, r_{d-1}, t_0, f_0, \forall p, 1 \leq p \leq d-2, \forall i_1, \ldots, i_p, 1 \leq i_1 < i_2 < \ldots, i_p \leq d-1, f_0^{i_1 \ldots i_p})$, and $\forall i, 1 \leq i \leq d-1, (r_0, r_1, \ldots, r_{i-1}, r_{i+1}, \ldots, r_{d-1}, t_1, f_1, \forall p, 1 \leq p \leq d-2, \forall i_1, \ldots i_p, 1 \leq i_1 < i_2 < \ldots i_p \leq d-1$, such that $\forall j \ i_j \neq i, \ f_1^{i_1 \ldots i_p}$) are accepted responses to $Ch = 0, 1, \ldots (d-1)$.

Theorem 10 The 3-pass protocol is proof of zero knowledge with zero knowledge error $\frac{d}{d+1}$ when the commitment scheme Com is computationally binding.

Proof sketch. Let $\forall i, 0 \leq i \leq d$, let $((c_0, c_1, c_2, \dots, c_{2d-2}), Ch_i, Rsp_i)$ be d + 1 transcripts such that $Ch_i = i$ and $Dec(F, v; (c_0, c_1, c_2, \dots, c_{2d-2}), Ch_i, Rsp_i) = 1$ for $i \in \{0, 1, 2, \dots, d\}$. Then, by using the four transcripts, we show that we are able either to break the binding property of *Com* or extract a solution for v. Consider the situation where the responses are parsed as

$$Rsp_0 = (\tilde{r}_1^{(0)}, \tilde{r}_2^{(0)}, \dots, \tilde{r}_{d-1}^{(0)}, \tilde{t}_0^{(0)}, \tilde{f}_0^{(0)},$$

$$\begin{aligned} \forall p, \ 1 \leq p \leq d-2, \ \forall i_1, \dots i_p, \ 1 \leq i_1 < i_2 < \dots i_p \leq d-1, \ \tilde{f}_0^{(0), i_1 \dots i_p}) \\ \forall i, \ 1 \leq i \leq d-1, \\ Rsp_i &= (\tilde{r}_0^{(i)}, \tilde{r}_1^{(i)}, \dots, \tilde{r}_{i-1}^{(i)}, \tilde{r}_{i+1}^{(i)}, \dots, \tilde{r}_{d-1}^{(i)}, \tilde{t}_1^{(i)}, \tilde{f}_1^{(i)}, \\ \forall p, \ 1 \leq p \leq d-2, \ \forall i_1, \dots i_p, \ 1 \leq i_1 < i_2 < \dots i_p \leq d-1, \\ \text{ such that } \forall j, \ i_j \neq i, \ \tilde{f}_1^{(i), i_1 \dots i_p}) \\ Rsp_d &= (\tilde{r}_1^{(d)}, \tilde{r}_2^{(d)}, \dots, \tilde{r}_{d-1}^{(d)}, \tilde{t}_1^{(0)}, \\ \forall p, \ 1 \leq p \leq d-2, \ \forall i_1, \dots i_p, \ 1 \leq i_1 < i_2 < \dots i_p \leq d-1, \\ \tilde{f}_1^{(d), i_1 \dots i_p}) \end{aligned}$$

We obtain:

$$\begin{split} c_{0} &= Com \Big(\tilde{r}_{1}^{(d)}, \dots, \tilde{r}_{d-1}^{(d)}, v - G(\tilde{t}_{1}^{(d)}, \tilde{r}_{1}^{(d)}, \dots, \tilde{r}_{d-1}^{(d)}) - \sum_{p=1}^{d-2} (-1)^{d-p} \\ &\sum_{1 \leq i_{1} < \dots < i_{p} \leq d-1} \tilde{f}_{1}^{(d),i_{1}\dots,i_{p}} - \\ (-1)^{d} \tilde{f}_{1}^{(d)} + \sum_{i=1}^{d} (-1)^{d-i} \sum_{s \in \binom{1,\dots,d-1}{|s| = i}} F(\sum_{j \in S} \tilde{r}_{j}^{(d)}) \Big) \\ &= Com \Big(\tilde{r}_{1}^{(0)}, \dots, \tilde{r}_{d-1}^{(0)}, G(\tilde{t}_{0}^{(0)}, \tilde{r}_{1}^{(0)}, \dots, \tilde{r}_{d-1}^{(0)}) + \sum_{p=1}^{d-2} (-1)^{d-p} \\ &\sum_{1 \leq i_{1} < \dots < i_{p} \leq d-1} \tilde{f}_{0}^{(0),i_{1}\dots,i_{p}} + (-1)^{d} \tilde{f}_{0}^{(0)} \Big) \\ &\forall i, 1 \leq i \leq d-1, \\ c_{2i-1} &= Com \Big(\tilde{r}_{1}^{(i)}, \dots, \tilde{r}_{i-1}^{(i)}, \tilde{r}_{i+1}^{(i)}, \dots, \tilde{r}_{d-1}^{(i)}, \tilde{r}_{0}^{(i)} - \tilde{t}_{1}^{(i)}, F(\tilde{r}_{0}^{(i)}) - \tilde{f}_{1}^{(i)}, \\ \forall p, 1 \leq p \leq d-2, \forall i_{1}, \dots, i_{p}, 1 \leq i_{1} < i_{2} < \dots, i_{p} \leq d-1, \\ \text{such that } \forall j, i_{j} \neq i, F(\tilde{r}_{0}^{(i)} + \tilde{r}_{i+1}^{(i)}, \dots, \tilde{r}_{d-1}^{(i)}, \tilde{t}_{0}^{(0)}, \tilde{f}_{0}^{(0)}, \\ \forall p, 1 \leq p \leq d-2, \forall i_{1}, \dots, i_{p}, 1 \leq i_{1} < i_{2} < \dots, i_{p} \leq d-1, \\ \text{such that } \forall j, i_{j} \neq i, \tilde{f}_{i-1}^{(0)}, \tilde{r}_{i+1}^{(i)}, \dots, \tilde{r}_{d-1}^{(i)}, \tilde{t}_{1}^{(i)}, \tilde{f}_{1}^{(i)}, \\ \forall p, 1 \leq p \leq d-2, \forall i_{1}, \dots, i_{p}, 1 \leq i_{1} < i_{2} < \dots, i_{p} \leq d-1, \\ \text{such that } \forall j, i_{j} \neq i, \tilde{f}_{i-1}^{(0),i_{1}\dots, i_{p}} \Big) \\ &= Com \Big(\tilde{r}_{1}^{(i)}, \dots, \tilde{r}_{i-1}^{(i)}, \tilde{r}_{i+1}^{(i)}, \dots, \tilde{r}_{d-1}^{(i)}, \tilde{t}_{1}^{(i)}, \tilde{f}_{1}^{(i)}, \\ \forall p, 1 \leq p \leq d-2, \forall i_{1}, \dots, i_{p}, 1 \leq i_{1} < i_{2} < \dots, i_{p} \leq d-1, \\ \text{such that } \forall j, i_{j} \neq i, \tilde{f}_{1}^{(i),i_{1}\dots, i_{p}} \Big) \\ &= Com \Big(\tilde{r}_{1}^{(d)}, \dots, \tilde{r}_{i-1}^{(d)}, \tilde{r}_{i+1}^{(d)}, \dots, \tilde{r}_{d-1}^{(d)}, \tilde{t}_{1}^{(d)}, \tilde{f}_{1}^{(d)}, \\ \forall p, 1 \leq p \leq d-2, \forall i_{1}, \dots, i_{p}, 1 \leq i_{1} < i_{2} < \dots, i_{p} \leq d-1, \\ \text{such that } \forall j, i_{j} \neq i, \tilde{f}_{1}^{(d),i_{1}\dots, i_{p}} \Big) \end{aligned}$$

If two tuples of the arguments of Com are are distinct on either of the above equations, the binding property of Com is broken. Otherwise the conditions on c_0 give:

$$\tilde{r}_1^{(0)} = \tilde{r}_1^{(d)}, \dots, \tilde{r}_{d-1}^{(0)} = \tilde{r}_{d-1}^{(d)}$$

$$v = G(\tilde{t}_0^{(0)} + \tilde{t}_1^{(d)}, \tilde{r}_1^{(d)}, \dots, \tilde{r}_{d-1}^{(d)}) + \sum_{p=1}^{d-2} (-1)^{d-p}$$
$$\sum_{1 \le i_1 < \dots < i_p \le d-1} (\tilde{f}_0^{(0), i_1 \dots i_p} + \tilde{f}_1^{(d), i_1 \dots i_p})$$
$$+ (-1)^d (\tilde{f}_0^{(0)} + \tilde{f}_1^{(d)}) - \sum_{i=1}^d (-1)^{d-i} \sum_{\substack{S \subset \{1, \dots, d-1\}\\|S| = i}} F(\sum_{j \in S} \tilde{r}_j^{(d)}) \Big)$$

The conditions on c_{2i-1} give:

The conditions on c_{2i} give:

We obtain:

More generally

$$F(\tilde{r}_{0}^{(1)} + \tilde{r}_{i_{1}}^{(d)} + \ldots + \tilde{r}_{i_{p}}^{(d)}) = F(\tilde{r}_{0}^{(1)} + \tilde{r}_{i_{1}}^{(1)} + \ldots + \tilde{r}_{i_{p}}^{(1)}) = \tilde{f}_{0}^{(1),i_{1}\dots i_{p}} + \tilde{f}_{1}^{(1),i_{1}\dots i_{p}} = \tilde{f}_{0}^{(0),i_{1}\dots i_{p}} + \tilde{f}_{1}^{(d),i_{1}\dots i_{p}}$$

Finally, we obtain

$$v = F(\tilde{r}_0^{(1)} + \tilde{r}_1^{(d)} + \ldots + \tilde{r}_{d-1}^{(d)})$$

This means that a solution $\tilde{r}_0^{(1)} + \tilde{r}_1^{(d)} + \ldots + \tilde{r}_{d-1}^{(d)}$ for v is extracted.
