# Smashing MASH-1* 

Vladimir Antipkin

#### Abstract

MASH-1 is modular arithmetic based hash function. It is presented in Part 4 of ISO/IEC 10118 standard for one and a half decade. Cryptographic strength of MASH-1 hash function is based on factorization problem of an RSA modulus along with redundancy in the input blocks of compression functions. Despite of this, we are able to introduce two large classes of moduli which allow practical time collision finding algorithm for MASH-1. In one case even multicollisions of arbitrary length can be constructed.

Keywords: hash-functions based on modular arithmetic, collision attack, MASH-1

## 1 Introduction

It becomes a common opinion that nowadays hash functions are working horses of modern cryptography. They are key ingredients in numerous schemes like public-key encryption, digital signatures, messageauthentication codes, or multiparty functionalities.

The last past years the focus on hash functions has dramatically increased, because of new attacks, mainly on MD hash functions family. All attention of cryptographic community was fixed on so called dedicated hash functions, or hash functions built upon a block cipher. As far as we know, hash-functions based on modular arithmetic raised not much interest in researches.

Hash functions based on modular arithmetic are particularly suitable for environments in which implementations of modular arithmetic of sufficient

[^0]length are already available. Anyway these hash functions are not widely adopted because of relatively poor performance.

Two constructions, MASH-1 and MASH-2 (for Modular Arithmetic Secure Hash), came as a result of a thorough design process and have been standardized in ISO/IEC 10118-4 [1] in 1998. The two hash functions differ only in the exponent used in the compression function while MASH-1 is obviously the fastest. Up to date there are no published results which would threaten security of any of these hash functions.

In this paper we present two classes of moduli which could be proper RSA moduli and simultaneously allow efficient construction of collisions for MASH-1 hash function. The fact of the existence of such moduli show that malicious third party who provide these moduli is able to forge users of MASH-1 algorithm.

## 2 Description of MASH hash functions

In this section we give brief description of MASH hash functions. For detailed description we refer to [1]. Let $N$ be an RSA modulus and $L_{N}$ denote its length in bits. Let $L_{\phi}$ be a number divisible by 16 and $L_{\phi}+1 \leq$ $L_{N} \leq L_{\phi}+16$. Properly padded input data $D$ of length divisible by $\frac{L_{\phi}}{2}$ is right-appended with $\frac{L_{\phi}}{2}$ bits denoting the binary representation of the length of the original (unpadded) data string. The resulting string is divided into a sequence of $q$ half-blocks: $D=D_{1}\|\ldots\| D_{q}, D_{i} \in V_{\frac{L_{\phi}}{2}}$, $i=1, \ldots, q$.

Every half-block $D_{i}$ is than expanded to full block $B_{i} \in V_{L_{\phi}}, i=1, \ldots, q$, in the following manner. Each consecutive half-byte of $D_{i}$ is prepended with a half-byte consisting of four binary ones, $i=1, \ldots, q$.

The hashing process consists of iteration of compression function and a finalization stage. Compression function $\phi: V_{L_{\phi}} \times V_{L_{\phi}} \rightarrow V_{L_{\phi}}$ is defined as follows:

$$
\phi\left(B_{i}, H_{i-1}\right)=\left(\left(\left(\left(H_{i-1} \oplus B_{i}\right) \vee E\right)^{e} \bmod N\right) \sim L_{\phi}\right) \oplus H_{i-1},
$$

where $H_{0}=I V$ is initialization vector fixed to all zeroes string, $E$ is a constant block equal to four ones (in the left-most position) followed by
$L_{\phi}-4$ zeros, exponent $e$ is equal to 2 for MASH- 1 and to 257 for MASH-2 (this is the only difference between these hash functions), $\sim$ is truncate operation to the corresponding number of right-most bits.

After all expanded data blocks proceed through compression function a finalization stage begins in the following manner. The intermediate block $H_{q}$ is represented as $H_{q}=H_{q 1}| | H_{q 2} \| H_{q 3}| | H_{q 4}, H_{q 1}, H_{q 2}, H_{q 3}, H_{q 4} \in V_{\frac{L_{\phi}}{4}}$. Then we define

$$
\begin{gathered}
Y_{0}=H_{q 3}, \quad Y_{1}=H_{q 1}, \quad Y_{2}=H_{q 4}, \quad Y_{3}=H_{q 2}, \\
Y_{i}=Y_{i-1} \oplus Y_{i-4}, \quad i=4, \ldots, 15, \\
D_{q+i}=Y_{2 i-2} \| Y_{2 i-1}, \quad i=1, \ldots, 8 .
\end{gathered}
$$

Data blocks $D_{q+i}, i=1, \ldots, 8$, are processed through expansion process and compression function iteration with $I V$ equal to $H_{q}$. As a result we obtain $H_{q+8} \in V_{L_{\phi}}$ and a hash value $H=H_{q+8} \bmod p$, where $p$ is a prime number with bit length at most $\frac{L_{\phi}}{2}$ and three high order bits equal to ones.

Up to date the best known (2nd) preimage and collision attacks on MASH hash functions are universal attacks, which require about $2^{\frac{L_{\phi}}{2}}$ and $2^{\frac{L_{\phi}}{4}}$ operations correspondingly. While to date no efficient attacks are known that exploit the factorization of the modulus, it is common opinion that knowledge of the factorization may reduce the security level. Therefore it is strongly recommended that factors of the modulus are kept secret. Our attacks (described below) do not take any advantage of knowledge of factors of the modulus.

## 3 First class of weak modulus of MASH-1

Let us first investigate the problem of finding fixed points of compression function, i.e. strings $H_{j-1}$ such that $\phi\left(B_{j}, H_{j-1}\right)=H_{j-1}$. We are looking for conditions on modulus $N$, strings $H_{j-1}$ and $B_{j}$, such that

$$
\begin{equation*}
\phi\left(B_{j}, H_{j-1}\right)=\left(\left(\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{e} \bmod N\right) \sim L_{\phi}\right) \oplus H_{j-1}=H_{j-1} . \tag{1}
\end{equation*}
$$

Equation (1) holds only if

$$
\begin{equation*}
\left(\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{e} \bmod N\right) \sim L_{\phi}=0 . \tag{2}
\end{equation*}
$$

Since $E \neq 0$ and $0<\left(H_{j-1} \oplus B_{j}\right) \vee E<2^{L_{\phi}}<N$, then

$$
\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{2} \bmod N \neq 0
$$

Last inequation means that (1) follows

$$
2^{L_{\phi}} \leq\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{2} \bmod N<N .
$$

Number of possible values of $\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{2} \bmod N$, for which equation (2) holds, do not exceed $\left\lfloor\frac{N}{2^{L_{\phi}}}\right\rfloor$, we can find all of them by exhaustive search. They have the form $2^{L_{\phi}} \cdot v, 1 \leq v \leq\left\lfloor\frac{N}{2^{L_{\phi}}}\right\rfloor$. But in general assumptions we do not know the factors of $N$ and so we are not able to find roots by modulus $N$. So we will consider only those numbers $2^{L_{\phi}} \cdot v$, for which we can find roots easily. These are numbers with integer roots. Since $L_{\phi}$ is an even number, than $2^{\frac{L_{\phi}}{2}}$ is a root from $2^{L_{\phi}}$. Consequently, it is necessary, that quadratic root of $v$ exists in integers. In the latter case, $A=2^{\frac{L_{\varphi}}{2}} \sqrt{v}$ is a root of $\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{2} \bmod N$ in integers. But $A<2^{\frac{L_{\phi}+16}{2}}$, and if $L_{\phi}>18$ than $A<2^{L_{\phi}-1}$. According to description of MASH-1 following inequality holds

$$
2^{L_{\phi}-1}<2^{L_{\phi}}-2^{L_{\phi}-4} \leq\left(H_{j-1} \oplus B_{j}\right) \vee E<2^{L_{\phi}} .
$$

Thus the value $A=2^{\frac{L_{\phi}}{2}} \sqrt{v}$ is not suitable.
Anyway, $A=N-2^{\frac{L_{\phi}}{2}} \sqrt{v}$ can be suitable: this number is also a root of $\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{2}$ by modulus $N$. We need that $2^{L_{\phi}}-2^{L_{\phi}-4} \leq A<2^{L_{\phi}}$, and following

$$
\begin{equation*}
2^{L_{\phi}}<N<2^{L_{\phi}}+2^{\frac{L_{\phi}}{2}} \sqrt{v} . \tag{3}
\end{equation*}
$$

Hence $L_{N}=L_{\phi}+1$ and according to $2^{L_{\phi}} \cdot v<N$ we have $v=1$, i.e. $\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{2} \bmod N=2^{L_{\phi}}$. In addition, following equality must hold

$$
\begin{equation*}
\left(H_{j-1} \oplus B_{j}\right) \vee E=N-2^{\frac{L_{\phi}}{2}} . \tag{4}
\end{equation*}
$$

Define $N=\sum_{i=0}^{L_{\phi} / 4} n_{i} 2^{4 i}, B_{j}=\sum_{i=0}^{L_{\phi} / 4-1} b_{i}^{(j)} 2^{4 i}, H_{j-1}=\sum_{i=0}^{L_{\phi} / 4-1} h_{i}^{(j-1)} 2^{4 i}, N-$ $2^{\frac{L_{\phi}}{2}}=\sum_{i=0}^{L_{\phi} / 4-1} w_{i} 2^{4 i}$. Relation (3) implies that

- $n_{L_{\phi} / 4}=1$,
- $w_{i}=n_{i}$ if $i<L_{\phi} / 8$,
- $n_{i}=0$ if $L_{\phi} / 8 \leq i<L_{\phi} / 4$,
- $w_{i}=0 x f$ if $L_{\phi} / 8 \leq i<L_{\phi} / 4$.

Here $0 x f$ is hexadecimal representation of 15 . Because of equation (4) and the fact, that $b_{i}^{(j)}=0 x f$ if $i$ is odd, following conditions on values of $h_{i}^{(j-1)}, b_{i}^{(j)}, n_{i}$ must hold:

$$
\begin{cases}h_{i}^{(j-1)} \oplus b_{i}^{(j)}=n_{i}, & \text { for even } i<L_{\phi} / 8  \tag{5}\\ h_{i}^{(j-1)}=n_{i} \oplus 0 x f, & \text { for odd } i<L_{\phi} / 8 \\ h_{i}^{(j-1)} \oplus b_{i}^{(j)}=0 x f, & \text { for even } L_{\phi} / 8 \leq i<L_{\phi} / 4-1 \\ h_{i}^{(j-1)}=0, & \text { for odd } L_{\phi} / 8<i<L_{\phi} / 4-1 \\ h_{i}^{(j-1)}, & - \text { arbitrary for } i=L_{\phi} / 4-1 \\ n_{i}=0, & \text { for } L_{\phi} / 8<i<L_{\phi} / 4 \\ n_{L_{\phi} / 4}=1 . & \end{cases}
$$

Fulfillment of these conditions implies (1). Obviously, these conditions are not contradictory.

If $j=1$ than $H_{0}=0$ and equation (1) holds if following conditions are satisfied:

$$
\begin{cases}n_{i}, & - \text { arbitrary for even } i<L_{\phi} / 8  \tag{6}\\ n_{i}=0 x f, & \text { for odd } i<L_{\phi} / 8 \\ n_{i}=0, & \text { for } L_{\phi} / 8 \leq i<L_{\phi} / 4 \\ b_{i}^{(j)}=n_{i}, & \text { for even } i<L_{\phi} / 8 \\ b_{i}^{(j)}=0 x f, & \text { for even } L_{\phi} / 8 \leq i<L_{\phi} / 4-1 \\ n_{L_{\phi} / 4}=1 . & \end{cases}
$$

Using the same approach it is possible to find intermediate and data values such that resulting compression function values differ only in one bit, i.e.

$$
\begin{equation*}
\phi\left(B_{j}, H_{j-1}\right)=\left(\left(\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{2} \bmod N\right) \sim L_{\phi}\right) \oplus H_{j-1}=H_{j-1} \oplus 2^{k} \tag{7}
\end{equation*}
$$

for certain $k, 0 \leq k<L_{\phi}$, or equivalently

$$
\begin{equation*}
\left(\left(\left(H_{j-1} \oplus B_{j}\right) \vee E\right)^{2} \bmod N\right) \sim L_{\phi}=2^{k} . \tag{8}
\end{equation*}
$$

Using similar computations we obtain that $k$ must be even, and following inequality should hold

$$
\begin{equation*}
2^{L_{\phi}}<N<2^{L_{\phi}}+2^{\frac{k}{2}} \tag{9}
\end{equation*}
$$

At the same time

$$
\begin{equation*}
\left(H_{j-1} \oplus B_{j}\right) \vee E=N-2^{\frac{k}{2}} \tag{10}
\end{equation*}
$$

From (9) we obtain that bits of $N$, starting from bit number $k / 2$, are all equal zero (with exception of bit number $L_{\phi}+1$ ), i.e.

- $n_{i}=0$ if $\left\lceil\frac{k}{8}\right\rceil \leq i<L_{\phi} / 4$;
- right-most $4-t$ bits of $n_{i}$ are equal zero if $i=\left\lfloor\frac{k}{8}\right\rfloor$ and $t \equiv\left(\frac{k}{2}\right)(\bmod$ 4), $t \neq 0$.

Denote $N-2^{\frac{k}{2}}=\sum_{i=0}^{L_{\phi} / 4-1} w_{i} 2^{4 i}$. Bits of $N-2^{\frac{k}{2}}$, starting from bit number $k / 2$, are all equal 1 , i.e.

- if $i \geq\left\lceil\frac{k}{8}\right\rceil$, then $w_{i}=0 x f$;
- if $i=\left\lfloor\frac{k}{8}\right\rfloor$, then right-most $4-t$ bits of $w_{i}$ are all equal 1 , where $t \equiv\left(\frac{k}{2}\right)(\bmod 4), t \neq 0$;
- other bits of $w_{i}$ coincide with corresponding bits of $n_{i}$.

Equation (10) holds if the following conditions on $h_{i}^{(j-1)}, b_{i}^{(j)}, n_{i}$ fulfill.

$$
\begin{cases}h_{i}^{(j-1)} \oplus b_{i}^{(j)}=n_{i}, & \text { for even } i<\lfloor k / 8\rfloor  \tag{11}\\ h_{i}^{(j-1)}=n_{i} \oplus 0 x f, & \text { for odd } i<\lfloor k / 8\rfloor \\ h_{i}^{(j-1)} \oplus b_{i}^{(j)}=0 x f, & \text { for even }\lceil k / 8\rceil \leq i<L_{\phi} / 4-1, \\ h_{i}^{(j-1)}=0, & \text { for odd }\lceil k / 8\rceil \leq i<L_{\phi} / 4-1, \\ h_{i}^{(j-1)}, & - \text { arbitrary for } i=L_{\phi} / 4-1, \\ h_{i}^{(j-1)}=w_{i} \oplus 0 x f, & \text { for odd } i=\lfloor k / 8\rfloor \\ h_{i}^{(j-1)} \oplus b_{i}^{(j)}=w_{i}, & \text { for even } i=\lfloor k / 8\rfloor \\ \text { right-most bits of } N & \text { starting from } \frac{k}{2} \text { are all equal zero, } \\ n_{L_{\phi} / 4}=1 & \end{cases}
$$

For $j=1$ and $H_{0}=0$ fulfilment of the following conditions is enough for equation (7) to hold.

$$
\begin{cases}b_{i}^{(1)}=n_{i}, & \text { for even } i<\lfloor k / 8\rfloor,  \tag{12}\\ n_{i}=0 x f, & \text { for odd } i<\lfloor k / 8\rfloor, \\ b_{i}^{(1)}=0 x f, & \text { for even }\lceil k / 8\rceil \leq i<L_{\phi} / 4-1, \\ w_{i}=0 x f, & \text { for odd } i=\lfloor k / 8\rfloor, \\ b_{i}^{(1)}=w_{i}, & \text { for even } i=\lfloor k / 8\rfloor, \\ \text { right-most bits of } N & \text { starting from } \frac{k}{2} \text { are all equal zero, } \\ n_{L_{\phi} / 4}=1 . & \end{cases}
$$

Analysis of (11) and (12) shows that if for some even $k$ conditions (11) or (12) hold, than these conditions hold for greater even values of $k$. It should be noticed that conditions (5) and (6) are particular cases of conditions (11) and (12) then $k=L_{\phi}$. From (9) it is easy to see, that decrease of the value of $k$, imply decrease of the set of such $N$, for which conditions (11) and (12) hold.

Proceeding from derived results, we will built a collision for MASH-1 with weak modulus. We choose $k=L_{\phi}-16$. Suppose modulus $N$ is chosen in such a way that 4th, 6th and 7th conditions of (12) are satisfied. We choose the first data block $B_{1}$ of the first message according to conditions of (12), the second data block $B_{2}$ of the first message - according to conditions of (5). In case $k=L_{\phi}-16$ such blocks exist ( $k / 8$ is even number). We choose the first data block $B^{\prime}{ }_{1}$ of the second message according to conditions of (6), the second data block $B^{\prime}{ }_{2}$ of the second message - according to conditions of (11). As a result, for the first message we obtain $H_{0}=I V=0, H_{1}=2^{k}, H_{2}=2^{k}$. For the second message we obtain $H^{\prime}{ }_{0}=I V=0, H^{\prime}{ }_{1}=0, H^{\prime}{ }_{2}=2^{k}$. Chosen messages are different, because they yield different intermediate values $H_{1}$ and $H^{\prime}{ }_{1}$. Chosen blocks have identical length, so they result in a collision for the whole hash function.

It is obvious, that described above construction can be easily transformed to obtain multi-collisions.

## 4 Second class of weak modulus of MASH-1

Now let us consider another approach for collision finding. We will look for so called single block collision or collision for compression function, i.e. we will try to find such values $H_{j-1}, B_{j}^{(1)}$ and $B_{j}^{(2)}$, that

$$
\begin{equation*}
\phi\left(B_{j}^{(1)}, H_{j-1}\right)=\phi\left(B_{j}^{(2)}, H_{j-1}\right) . \tag{13}
\end{equation*}
$$

From (13) it follows that $\left(\left(\left(H_{j-1} \oplus B_{j}^{(1)}\right) \vee E\right)^{2} \bmod N\right) \sim L_{\phi}=\left(\left(\left(H_{j-1} \oplus B_{j}^{(2)}\right) \vee E\right)^{2} \bmod N\right) \sim L_{\phi}$, which deliberately holds if

$$
\left(\left(H_{j-1} \oplus B_{j}^{(1)}\right) \vee E\right)^{2} \equiv\left(\left(H_{j-1} \oplus B_{j}^{(2)}\right) \vee E\right)^{2} \bmod N .
$$

Since we do not know the factors of $N$, we can only examine the case

$$
\left(\left(H_{j-1} \oplus B_{j}^{(1)}\right) \vee E\right)=-\left(\left(H_{j-1} \oplus B_{j}^{(2)}\right) \vee E\right)(\bmod N),
$$

i.e.

$$
\begin{equation*}
\left(\left(H_{j-1} \oplus B_{j}^{(1)}\right) \vee E\right)+\left(\left(H_{j-1} \oplus B_{j}^{(2)}\right) \vee E\right)=N . \tag{14}
\end{equation*}
$$

Define $A_{1}=\left(H_{j-1} \oplus B_{j}^{(1)}\right) \vee E$ and $A_{2}=\left(H_{j-1} \oplus B_{j}^{(2)}\right) \vee E$. From (14) it follows that $L_{N}=L_{\phi}+1$ and at least 4 right-most bits of $N$ are all equal to 1. Half-bytes of $A_{1}$ and $A_{2}$ with odd numbers coincide and are equal to $h_{i}^{(j-1)} \oplus 0 x f, i=1,3, \ldots$, with the exception of right-most half-byte, which is equal to $0 x f$.

Further we will investigate if modulus $N$ can be represented as a sum of $A_{1}$ and $A_{2}$. Define $A_{j}=\sum_{i=0}^{L_{\phi} / 4-1} a_{i}^{(j)} 2^{4 i}, j=1,2$. We have

$$
\begin{equation*}
N=A_{1}+A_{2}=\sum_{i=0}^{L_{\phi} / 8-1}\left(a_{2 i}^{(1)}+a_{2 i}^{(2)}\right) 2^{8 i}+\sum_{i=0}^{L_{\phi} / 8-1} 2 a_{2 i+1}^{(1)} 2^{8 i+4} \tag{15}
\end{equation*}
$$

Hence three right-most bits of each half-byte with odd number of $N$ equal three left-most bits of corresponding half-byte with odd number of $A_{1}$ and $A_{2}$.

Let us consider the left-most five bits of $N$. It follows from (15), that they should be equal to binary representation of $a_{0}^{(1)}+a_{0}^{(2)}$. On the other hand $a_{0}^{(1)}+a_{0}^{(2)} \leq 15+15<31$. Hence if all five left-most bits of $N$ are equal to 1 , i.e. $N \equiv 31(\bmod 32)$, than $N$ can not be represented as a sum $A_{1}+A_{2}$. If at least one of five left-most bits is equal to zero, than we can obtain $a_{0}^{(1)} \neq a_{0}^{(2)}$ in such a way, that five left-most bits of $N$ are equal to $a_{0}^{(1)}+a_{0}^{(2)}$.

Let us consider the bits of $N$ with numbers starting from $8 i$ to $8 i+4$. These bits are equal to binary representation if $a_{2 i}^{(1)}+a_{2 i}^{(2)}+\varepsilon$, where $\varepsilon$ is a bit of $A_{1}$ with number $8 i-1$. Obviously, for every values of these bits of $N$, it is always possible to obtain such $a_{2 i}^{(1)}, a_{2 i}^{(2)}, \varepsilon$, that their sum possesses the necessary value.

Hence, if $L_{N}=L_{\phi}+1,4$ right-most bits of $N$ are equal to 1 and $N \neq 31(\bmod 32)$, than we can always obtain such numbers $A_{1}$ and $A_{2}$ (and $A_{1} \neq A_{2}$ ), that $N=A_{1}+A_{2}$ and half-bytes of $A_{1}$ and $A_{2}$ with even numbers coincide.

Let $N$ be represented in the mentioned above manner. We chose as $H_{j-1}$ an arbitrary number, that is less then $2^{L_{\phi}}$, and whose half-bytes with odd numbers are inverse of half-bytes with odd numbers of $A_{1}$ (with exception of right-most half-byte). Than we can obtain such $B_{j}^{(1)}$ and $B_{j}^{(2)}$, that $A_{i}=\left(H_{j-1} \oplus B_{j}^{(i)}\right) \vee E, i=1,2$. In this case (13) holds and we get a collision for compression function (with chosen value of $H_{j-1}$ ).

Let us consider the case $j=1$. This lead us to the following additional condition: half-bytes of $A_{1}$ and $A_{2}$ with odd numbers are equal to $0 x f$. This follows that bits of $N$ with numbers $8 t_{1}+t_{2}, t_{1}=0,1, \ldots, t_{2} \in$ $\{5,6,7\}$, must be equal to 1 , and each set of five bits with numbers $8 t_{1}, 8 t_{1}+$ $1, \ldots, 8 t_{1}+4, t_{1}=1,2, \ldots$ must contain at least one bit equal to 1 . In this case it is possible to represent $N$ as a sum $A_{1}+A_{2}$. Now we are left to take as $B_{1}^{(1)}$ and $B_{1}^{(2)}$ the values $A_{1}$ and $A_{2}$, and obtain a collision.

## 5 Conclusion

We have demonstrated the existence of weak moduli which lead to total break of collision resistance of MASH-1 hash function. Our attacks do not use any knowledge of secret factors of the modulus. Users of MASH-1 hash function can be enforced to use weak modulus by malicious third party who is capable of their generation.
