# FeW: A Lightweight Block Cipher 

Manoj Kumar ${ }^{1,2}$, Saibal K. Pal ${ }^{1}$ and Anupama Panigrahi ${ }^{2}$<br>${ }^{1}$ Scientific Analysis Group, DRDO, Delhi, INDIA<br>${ }^{2}$ Department of Mathematics, University of Delhi, INDIA mktalyan@yahoo.com

#### Abstract

In this paper, we propose a new lightweight block cipher called FeW ${ }^{1}$ which encrypts 64-bit plaintext using key size 80/128 bits and produces 64-bit ciphertext. FeW is a software oriented design with the aim of achieving high efficiency in software based environments. We use a mix of Feistel and generalised Feistel structures (referred as Feistel-M structure hereinafter) to enhance the security of our design against basic cryptanalytic attacks like differential, linear, impossible differential and zero correlation attacks. Security analysis of this scheme proves its strength against present day cryptanalytic attacks.

Keywords: Block Cipher, Feistel structure, Generalised Feistel structure, Lightweight Cryptography, SPN

## 1. Introduction

Lightweight cryptography [26] has emerged as a vast research direction in the area of cryptography. Research in this direction started in the beginning of $21^{\text {st }}$ century to meet the requirement of cryptographic algorithms requiring very low implementation area and less power consumption. There was requirement for product designers and developers to provide security features in tiny and handheld devices. This was the time when Rijndael [10] was selected as AES and there was a need for lightweight ciphers for specific applications. RFID tags and sensor networks are the examples of products that employ lightweight cryptographic algorithms. Lightweight block ciphers like PRESENT [4], HIGHT [14], LBlock [38], TWINE [34], SIMON and SPECK family [7], TEA [39], DES Light weight variant [23] and other lightweight designs [8,12,13,19,31,40,15,22,35] with different design constructions [20] have been published in last 15 years. PRESENT and CLEFIA have been chosen as a lightweight encryption standard by International Organisation of Standardisation (ISO) and International Electro-technical Commission. Wide publicity of PRESENT, inspired researchers to designs new and more efficient lightweight block cipher. Various new cryptanalytic attacks and their combinations [21] have also been discovered and applied on block ciphers in last few years. Some cryptanalytic attacks have been applied on full round ciphers and some have been shown to be prone to various attacks.

[^0]Lightweight block cipher designs are mainly based on two structures: Feistel and SPN. The concept of confusion and diffusion given by Shannon [29] is used in both structures to design the secure cryptographic algorithms. These design principles are still the best concept to design a new block ciphers. Feistel structure was proposed by Horst Feistel and the first block cipher design based on this structure was LUCIFER [28]. In this structure, input plaintext is encrypted by dividing it in two equal parts and using a round function (comprising of non-linear substitution and linear permutation which gives confusion and diffusion) on one part while the other part remains unchanged for the next round. DES [6] is the first widely used Feistel Network based block cipher design which was in use for almost two decades. Schneier and Kelsey [32] examined the concept given by Feistel and they generalized this structure and called it unbalanced Feistel networks (UFNs). UFNs consists a series of rounds in which one part of block operates on the rest of the block. However, in a UFN the two parts need not be of same size. But UFNs did not receive much attention from the cryptographic community for designing the block cipher. The first choice between balance Feistel network (BFN) and UFN is obviously BFN based designs. Generalized balance Feistel networks are the generalization of Balance Feistel which encrypts the plaintext block by dividing it into $n$ equal parts. If the confusion and diffusion is applied on the whole block length in each round while encryption then the structure is called SPN. In this structure we require that round subkeys are of same size as block length. The current cryptographic standard for block ciphers AES [10] have been designed using the SPN structure.
As compared to SPN based ciphers, Feistel based ciphers seem to be a better choice for lightweight ciphers as it does not need inversion of the round function and inverse of S-box involved in round function. Feistel based design performs less computation as compared to SPN based designs, because half of the input block is processed through round function, whereas SPN based designs apply substitution and permutation on full input block in every round. Therefore we choose the Feistel structure with SPN round function to design a new lightweight block cipher. Some previous designs also have used similar operations in round function as we have used in our design. SMS4 [9] block cipher is used in Chinese WAPI standard which uses shifts and xor on 32 bit words in its round function and key scheduling. We have used two different shift and xor operations on 16 bit words inside the round function. Key schedule of FeW is designed using the key expansion concept similar to the PRESENT. Generalised Feistel based designs CLEFIA [36] have used two different round functions but we have used two different functions which are applied on mixed input data of two 16 bit Feistel branches. Our design is based on Feistel-M structures, which proves to be very helpful in enhancing the security of our design against cryptanalytic attacks.

This paper is organised as follows. In section 2, we describe the design specifications of lightweight block cipher FeW in detail. Key schedule for key size 80 -bit is presented in section 3. Security evaluation of FeW against some basic cryptanalytic attacks is described in section 4. Finally, we conclude the paper in section 5.

Notations: We have used the following notations in this paper while describing the lightweight block cipher FeW:

| - | $\mathrm{P}_{\mathrm{m}}:$ | 64-bit input plaintext block |
| :--- | :--- | :--- |
| - | $\mathrm{C}_{\mathrm{m}}:$ | 64-bit output ciphertext block |
| - | $\mathrm{MK}-80:$ | 80-bit user supplied key |
| - | $\mathrm{MK}-128:$ | 128-bit user supplied key |
| - | $\mathrm{RK}_{\mathrm{i}}:$ | 16-bit subkey extracted from Key register MK |
| - | $\mathrm{K}_{\mathrm{i}}:$ | 32-bit subkey for round i (concatenation of $\mathrm{RK}_{2 \mathrm{i}}$ and $\mathrm{RK}_{2 \mathrm{i}+1}$ ) |
| - | $\mathrm{F}:$ | Round function |
| - | $\mathrm{WF}_{1}:$ | Weight Function 1 used inside F |
| - | $\mathrm{WF}_{2}:$ | Weight Function 2 used inside F |
| - | $\oplus$ | Bitwise exclusive-OR operation |
| - | $\lll \mathrm{n}$ | Left cyclic shift by $n$ bits |
| - | $\gg \mathrm{n}$ | Right shift by $n$ bits |
| - | $[\mathrm{i}]_{2}$ | Binary representation of integer i |
| - | $\\|:$ | Concatenation of two bit strings |
| - | $\&:$ | Bitwise And between two bit strings |

## 2. FeW: Lightweight Block Cipher

We describe the Encryption algorithm and Key Schedule of lightweight block cipher FeW in this section:

### 2.1 Specifications of $\mathbf{F e W}$

FeW encrypts plaintext in blocks of size 64 bits (This is the commonly preferred block size in case of lightweight block ciphers). Design of FeW (Fig.1) is based on Feistel-M structure which is broadly a Balanced Feistel based design but its round function process 32 bit word like generalised Feistel based designs. The round function F uses two different functions $\mathrm{WF}_{1}$ and $\mathrm{WF}_{2}$ and applies these on two 16 bit words. This type of mixing method is used first time in a block cipher. We have shown that this significantly improves the immunity of our design against cryptanalytic attacks.
FeW takes 64 -bit of plaintext data as input and produces a 64 -bit data of ciphertext as output. There are total 32 rounds in FeW . We obtain 64-bit ciphertext by swapping the output words of the last round. FeW uses two options for the size of Master key MK: 80 bits and 128 bits. Based on two key sizes, we name the two versions of FeW , the first version with 80 -bit key size as $F e W-80$ and the second version with 128 -bit key size as FeW-128.

Fig.1: One round of FeW (Feistel-M)

### 2.2 Encryption Algorithm

First we divide 64-bit plaintext $\mathrm{P}_{\mathrm{m}}$ into two halves namely $\mathrm{P}_{0}$ and $\mathrm{P}_{1}$. Each of these halves is of size 32-bit. We have 64-bit input plaintext $\mathrm{P}_{\mathrm{m}}$ as concatenation of two 32-bit words $\mathrm{P}_{0}$ and $\mathrm{P}_{1}$ as follows:

$$
\mathrm{P}_{0} \| \mathrm{P}_{1} \leftarrow \mathrm{P}_{\mathrm{m}}
$$

Encryption procedure of FeW is described as follows:
(a) For $\mathrm{i}=0$ to 31 , apply round functions F on 32-bit word $\mathrm{P}_{\mathrm{i}+1}$ and xor it with $\mathrm{P}_{\mathrm{i}}$ to produce $\mathrm{P}_{\mathrm{i}+2}$ :

$$
\mathrm{P}_{\mathrm{i}+2} \leftarrow \mathrm{P}_{\mathrm{i}} \oplus \mathrm{~F}\left(\mathrm{P}_{\mathrm{i}+1}, \mathrm{~K}_{\mathrm{i}}\right)
$$

(b) Apply swap function on the output of the last round:

$$
\left(\mathrm{P}_{33}, \mathrm{P}_{32}\right) \leftarrow\left(\mathrm{P}_{32}, \mathrm{P}_{33}\right)
$$

(c) We obtain two 32 bit ciphertext words:

$$
\left(\mathrm{C}_{0}, \mathrm{C}_{1}\right) \leftarrow\left(\mathrm{P}_{33}, \mathrm{P}_{32}\right)
$$

Finally, we obtain the 64-bit ciphertext $\mathrm{C}_{\mathrm{m}}$ as concatenation of $\mathrm{C}_{0}$ and $\mathrm{C}_{1}$ as follows:

$$
\mathrm{C}_{\mathrm{m}} \leftarrow \mathrm{C}_{0} \| \mathrm{C}_{1}
$$

Now we describe below the Round functions F in detail:

### 2.3 Round function $F$

F is the round function of FeW and its internal structure is shown in Fig 2. It takes 32 bit input $X_{i}$ and produces 32 bit output $\mathrm{Y}_{\mathrm{i}}$.

$$
\text { F: }\{0,1\}^{32} \rightarrow\{0,1\}^{32}
$$

We have used two different weight functions $\mathrm{WF}_{1}$ and $\mathrm{WF}_{2}$ inside F , both of these functions take 16 bit input and produce 16 bit output. Weight functions $\mathrm{WF}_{1}$ and $\mathrm{WF}_{2}$ are described in section 2.3.1 and 2.3.2 in detail. In each round, $F$ is applied on 32 bit input $X_{i}$ as follows:
(i) $\quad \mathrm{X}_{\mathrm{i}} \oplus \mathrm{K}_{\mathrm{i}}$
(ii) $\quad \mathrm{C}_{(8)}\left\|\mathrm{D}_{(8)}\right\| \mathrm{E}_{(8)} \| \mathrm{F}_{(8)}$
(iii) $\quad\left(\mathrm{A}=\mathrm{C}_{(8)} \| \mathrm{F}_{(8)}\right) \|\left(\mathrm{B}=\mathrm{E}_{(8)} \| \mathrm{D}_{(8)}\right)$
$\mathrm{A} \& \mathrm{~B}$ are processed through weight functions $\mathrm{WF}_{1}$ and $\mathrm{WF}_{2}$. Finally, 32-bit output $\mathrm{Y}_{\mathrm{i}}$ is the concatenating of 16 -bit outputs from $\mathrm{WF}_{1}$ and $\mathrm{WF}_{2}$. This 32 -bit output $\mathrm{Y}_{\mathrm{i}}$ from round function $F$ is xored with 32-bit word $P_{i}$ to get $P_{i+2}$ as described below:

$$
\begin{aligned}
& \mathrm{P}_{\mathrm{i}+2} \leftarrow \mathrm{P}_{\mathrm{i}} \oplus \mathrm{~F}\left(\mathrm{X}_{\mathrm{i}}\right) \\
& \text { i.e. } \mathrm{P}_{\mathrm{i}+2} \leftarrow \mathrm{P}_{\mathrm{i}} \oplus \mathrm{Y}_{\mathrm{i}}
\end{aligned}
$$

Fig. 2: Round Function F

### 2.3.1 Weight Function $\mathbf{W F}_{1}$

This function takes 16 -bit input and produces 16 -bit output. Weight function $\mathrm{WF}_{1}$ consists of application of S-box 4 times in parallel as non-linear operation and cyclic shifts and exclusive-or operation as linear mixing operation $L_{1}$. Weight function $\mathrm{WF}_{1}$ is described below in detail:

$$
\begin{gathered}
\mathrm{WF}_{1}:\{0,1\}^{16} \longrightarrow\{0,1\}^{16} \\
\mathrm{Y} \leftarrow \mathrm{WF}_{1}\left(\mathrm{~A}=\mathrm{A}_{0}\left\|\mathrm{~A}_{1}\right\| \mathrm{A}_{2} \| \mathrm{A}_{3}\right)
\end{gathered}
$$

First, we apply $4 \times 4$ S-box in parralal 4 times on $A$ to get $U$ then apply cyclic shifs on $U$ and xor these with U to get Y as output of function $\mathrm{WF}_{1}$ as follows:

$$
\begin{gathered}
\mathrm{U}_{0} \leftarrow \mathrm{~S}\left(\mathrm{~A}_{0}\right) \\
\mathrm{U}_{1} \leftarrow \mathrm{~S}\left(\mathrm{~A}_{1}\right) \\
\mathrm{U}_{2} \leftarrow \mathrm{~S}\left(\mathrm{~A}_{2}\right) \\
\mathrm{U}_{3} \leftarrow \mathrm{~S}\left(\mathrm{~A}_{3}\right) \\
\mathrm{U} \leftarrow\left(\mathrm{U}_{0}\left\|\mathrm{U}_{1}\right\| \mathrm{U}_{2} \| \mathrm{U}_{3}\right) \\
\mathrm{Y} \leftarrow(\mathrm{U} \oplus \mathrm{U} \lll 1 \oplus \mathrm{U} \lll 5 \oplus \mathrm{U} \lll 9 \oplus \mathrm{U} \lll 12)
\end{gathered}
$$

### 2.3.2 Weight Function $\mathbf{W F}_{2}$

Similar to $\mathrm{WF}_{1}, \mathrm{WF}_{2}$ also takes 16 -bit input and produces 16 -bit output. $\mathrm{WF}_{2}$ consists of application of S -box 4 times in parallel and apply cyclic shifts on V and xor these with V to get Z as output of $\mathrm{WF}_{2}$ as linear mixing operation $\mathrm{L}_{2}$ which is different from $\mathrm{L}_{1} . \mathrm{WF}_{2}$ is described below in detail:

$$
\mathrm{WF}_{2}:\{0,1\}^{16} \rightarrow\{0,1\}^{16}
$$

$$
\mathrm{Z} \longleftarrow \mathrm{WF}_{2}\left(\mathrm{~B}=\mathrm{B}_{0}\left\|\mathrm{~B}_{1}\right\| \mathrm{B}_{2} \| \mathrm{B}_{3}\right)
$$

First, we apply 4 x 4 S-box in parralal 4 times on B to get V then apply shift and xor V to get Z as output of function $\mathrm{WF}_{2}$ as follows:

$$
\begin{gathered}
\mathrm{V}_{0} \leftarrow \mathrm{~S}\left(\mathrm{~B}_{0}\right) \\
\mathrm{V}_{1} \leftarrow \mathrm{~S}\left(\mathrm{~B}_{1}\right) \\
\mathrm{V}_{2} \leftarrow \mathrm{~S}\left(\mathrm{~B}_{2}\right) \\
\mathrm{V}_{3} \leftarrow \mathrm{~S}\left(\mathrm{~B}_{3}\right) \\
\mathrm{V} \leftarrow \mathrm{~V}_{0}\left\|\mathrm{~V}_{1}\right\| \mathrm{V}_{2} \| \mathrm{V}_{3} \\
\mathrm{Z} \leftarrow \mathrm{~V} \oplus \mathrm{~V} \lll 4 \oplus \mathrm{~V} \lll 7 \oplus \mathrm{~V} \lll 11 \oplus \mathrm{~V} \lll 15
\end{gathered}
$$

### 2.4 S-Box

We have used the same $4 \times 4$ S-box in encryption, decryption and key schedule of lightweight block cipher $\mathrm{FeW}-80$ and $\mathrm{FeW}-128$. This S-box has already been used in block cipher HummingBird2 [11]. Saarinan [30] also has given cryptographic analysis of all $4 \times 4$ bit S-boxes and this S-box falls in the category of Golden S-boxes:

| x | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | A | B | $C$ | $D$ | $E$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |$|$

Table 1: S-box S

### 2.5 Key Schedule for MK-80

There is no related key attack reported on PRESENT like key schedule till now. We also prefer the same type of key schedule for our design. First, store MK-80 in a key register called MK as

$$
\mathrm{MK}=\mathrm{k}_{0} \mathrm{k}_{1} \mathrm{k}_{2} \mathrm{k}_{3} . . . . . . . . . . . \mathrm{k}_{78} \mathrm{k}_{79} .
$$

We obtain round subkeys $\mathrm{RK}_{0}$ by extracting leftmost 16 bits of current contents of MK and proceed in the following way to obtain the other round subkeys:
a. While $i<64$, update the register MK in the following steps:

1. $\mathrm{MK} \lll<13$
2. $\left[\mathrm{k}_{0} \mathrm{k}_{1} \mathrm{k}_{2} \mathrm{k}_{3}\right] \leftarrow \mathrm{S}\left[\mathrm{k}_{0} \mathrm{k}_{1} \mathrm{k}_{2} \mathrm{k}_{3}\right]$ $\left[\mathrm{k}_{64} \mathrm{k}_{65} \mathrm{k}_{66} \mathrm{k}_{67}\right] \leftarrow \mathrm{S}\left[\mathrm{k}_{64} \mathrm{k}_{65} \mathrm{k}_{66} \mathrm{k}_{67}\right]$ $\left[\mathrm{k}_{76} \mathrm{k}_{77} \mathrm{k}_{78} \mathrm{k}_{79}\right] \leftarrow \mathrm{S}\left[\mathrm{k}_{76} \mathrm{k}_{77} \mathrm{k}_{78} \mathrm{k}_{79}\right]$
3. $\left[\mathrm{k}_{68} \mathrm{k}_{69} \mathrm{k}_{70} \mathrm{k}_{71} \mathrm{k}_{72} \mathrm{k}_{73} \mathrm{k}_{74} \mathrm{k}_{75}\right] \leftarrow\left[\mathrm{k}_{68} \mathrm{k}_{69} \mathrm{k}_{70} \mathrm{k}_{71} \mathrm{k}_{72} \mathrm{k}_{73} \mathrm{k}_{74} \mathrm{k}_{75}\right] \oplus[\mathrm{i}]_{2}$
b. Increment $i$ by 1 and extract leftmost 16 bits of current contents of MK as round subkey $\mathrm{RK}_{\mathrm{i}}$.

## 3. Security Analysis

There is a large variety of cryptanalytic attacks which can be applied on block ciphers. We give secrurity estimates of our design against some basic cryptanalytic attacks in this section.

### 3.1 Differential Cryptanalysis

Differential attack [6] is one of the most basic cryptanalytic attacks applied on block ciphers. This attack was invented by Biham and Shamir in 1990 and applied on DES. This attack exploits the high probability differences in input and ouput of an encryption system and these high probability input and output occurences of certain pairs are used to recover round subkeys from the outermost rounds. Linear components of a cipher produces the certain outputs with probability 1 , while this is not the case for the non linear components (S-box in our design). These are examined and high probability input and output differences of these componenets (S-box) are used to form differential trail of the cipher by joining 1 round high probability differentials trails. FeW uses a $4 \times 4 \mathrm{~S}$-box as its only non linear component. We give a Difference Distribution table (DDT) for this S-box by counting the occurences of all possible input and output differences. DDT (16x16) of Sbox is given in table 5 (Appendix D).
Maximum differential probability for arbitrary input difference producing a output difference in a single S-box application is $4 / 16=2^{-2}$. This value ensures that even if there is only one active $S$-box in each round, still differential attack will require $2^{64}$ chosen palintexts(full codebook) to distinguish it from random permutation.

### 3.1.1 Experimental results on $L_{1}$ and $L_{2}$

We applied $L_{1}$ and $L_{2}$ on all possible input differences and observed the output differences using computer programs, the following observations (table 2 ) are made between input and output differences which are very useful in proving our design secure against the Differential and Linear attacks:

| Minimum number of non zero nibbles <br> $\left(\mathrm{L}_{1}\right.$ and $\left.\mathrm{L}_{2}\right)$ |  |
| :---: | :---: |
| Input Difference | Output Difference |
| 1 | 4 |
| 2 | 3 |
| 3 | 2 |
| 4 | 1 |

Table 2: Number of non zero nibbles
There are two cases on the bases of observations made on linear permutation layers of round functions $\mathrm{WF}_{1}$ and $\mathrm{WF}_{2}$ :

1. Input difference with 1 non zero nibble gives output difference with at least 4 non zero nibbles and next round input difference with 4 non zero nibbles produces output difference with 1 non zero nibble and vice versa.
2. Input difference with 2 non-zero nibbles gives 3 non zero nibbles and the process continues with 3 non zero nibbles as input to the next round and 2 non zero nibbles as output and vice versa.

Branch number of a function is defined by Rijmen [27] and Kanda [16] for SPN based designs and Feistel based designs with SPN type round function. We define below the Branch number of the linear permutation layers used in FeW and differential \& linear Branch number of FeW . We use the similar techniques as in $[18,37]$ to show the resistance of FeW to Differential and linear attacks.

Definition 1: (Branch Number) If X is 16 bit input to the function $f$ and X is written as concatenation of 4 nibbles $x_{0}, x_{1}, x_{2}$ and $x_{3}$ each of size 4 bit. By defining the number of non zero nibbles in $f$ by $\operatorname{Hw}(f)$, we define the branch number of the function

$$
f:\{0,1\}^{16} \rightarrow\{0,1\}^{16}
$$

by $\beta(f)$ as follows:

$$
\beta(f)=\min _{\mathrm{X} \neq 0, \mathrm{X} \in\{0,1\}^{16}}(\mathrm{Hw}(\mathrm{X})+\mathrm{Hw}(f(\mathrm{X}))
$$

Definition 2: Differential Branch number $\beta_{d}$ of a linear permutation layer $L$ is defined as:

$$
\beta_{\mathrm{d}}(\mathrm{~L})=\underset{\Delta \mathrm{X} \neq 0, \mathrm{X}_{1}, \mathrm{X}_{2} \in\{0,1\}^{16}}{\min }(\operatorname{Hw}(\Delta \mathrm{X})+\operatorname{Hw}(\mathrm{L}(\Delta \mathrm{X}))
$$

where $\Delta \mathrm{X}=\mathrm{X}_{1} \oplus \mathrm{X}_{2}$ is input difference to the linear layers of FeW and $\mathrm{L}(\Delta \mathrm{X})=\mathrm{L}\left(\mathrm{X}_{1}\right)$ $\oplus \mathrm{L}\left(\mathrm{X}_{2}\right)$ is output difference. In case of FeW , Differential Branch number of the linear layer $L_{1}$ and $L_{2}$ used in $F$ is 5 , which is verified by a Computer programme (Table 2).

Theorem 1: If $\mathrm{P}_{\mathrm{i}} \| \mathrm{P}_{\mathrm{i}+1}$ is the 64-bit input to $\mathrm{i}^{\text {th }}$ round of FeW and $\mathrm{X}_{\mathrm{i}}$ is the 32 bit input and $Y_{i}$ is the 32 bit output to the round function $F$ at $i^{\text {th }}$ round. We obtain the following relationship between the input and output of three consecutive rounds (i.e. $\mathrm{i}^{\text {th }}, i+1^{\text {th }}$ and $i+2^{\text {th }}$ rounds).

$$
X_{i} \oplus X_{i+2}=Y_{i+1}
$$

Proof: We draw 3 rounds of FeW in Fig. 3, We consider structure of FeW broadly a Feistel structure. We have the following relations between the intermediate states, input and output to the round function:

$$
\begin{align*}
& \mathrm{X}_{\mathrm{i}}=\mathrm{P}_{\mathrm{i}+1}  \tag{i}\\
& \mathrm{X}_{\mathrm{i}+1}=\mathrm{P}_{\mathrm{i}+2}  \tag{ii}\\
& \mathrm{X}_{\mathrm{i}+2}=\mathrm{P}_{\mathrm{i}+3}  \tag{iii}\\
& \mathrm{Y}_{\mathrm{i}}=\mathrm{P}_{\mathrm{i}} \oplus \mathrm{P}_{\mathrm{i}+2}  \tag{iv}\\
& \mathrm{Y}_{\mathrm{i}+1}=\mathrm{P}_{\mathrm{i}+1} \oplus \mathrm{P}_{\mathrm{i}+3}  \tag{v}\\
& \mathrm{Y}_{\mathrm{i}+2}=\mathrm{P}_{\mathrm{i}+2} \oplus \mathrm{P}_{\mathrm{i}+4} \tag{vi}
\end{align*}
$$

We have the following desired relation using equations (i), (iii) \& (v) between input and output to the round function W :

$$
\begin{equation*}
\mathrm{Y}_{\mathrm{i}+1}=\mathrm{X}_{\mathrm{i}} \oplus \mathrm{X}_{\mathrm{i}+2} \tag{vii}
\end{equation*}
$$

Fig. 3: Three consecutive rounds of FeW (Broadly Feistel structure)
Theorem 2: If $\Delta \mathrm{X}_{\mathrm{i}} \oplus \Delta \mathrm{X}_{\mathrm{i}+2}$ is not equal to zero, then three consecutive rounds of FeW have at least 5 differentially active S -boxes.

Proof: We denote the linear transformation layers ( $L_{1}$ and $L_{2}$ ) in round function $F$ by $L$ and use theorem 1 with linearity of L , we have the following relation:

$$
\begin{equation*}
\Delta \mathrm{X}_{\mathrm{i}} \oplus \Delta \mathrm{X}_{\mathrm{i}+2}=\Delta \mathrm{Y}_{\mathrm{i}+1}=\mathrm{L}\left(\mathrm{~L}^{-1}\left(\Delta \mathrm{Y}_{\mathrm{i}+1}\right)=\mathrm{L}\left(\Delta \mathrm{~L}^{-1}\left(\mathrm{Y}_{\mathrm{i}+1}\right)\right)\right. \tag{viii}
\end{equation*}
$$

Since applying inverse of L on the output to round function at round i , we get the same number of non zero nibbles as there are in the input to round function. Therefore, we have the following relation:

$$
\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}+1}\right)=\operatorname{Hw}\left(\Delta \mathrm{L}^{-1}\left(\mathrm{Y}_{\mathrm{i}+1}\right)\right)
$$

We know the relation $\operatorname{Hw}(\alpha)+\operatorname{Hw}(\beta) \geq \operatorname{Hw}(\alpha \oplus \beta)$ between the number of non zero nibbles in two binary strings $\alpha$ and $\beta$ [16]. Using this relation, we get:

$$
\begin{equation*}
\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}}\right)+\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}+2}\right) \geq \operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}} \oplus \Delta \mathrm{X}_{\mathrm{i}+2}\right) \tag{x}
\end{equation*}
$$

Using (viii), (ix) \& (x) and $\beta_{d}(L)$ we have the following relation which asserts that any 3 consecutive rounds will have at least 5 differentially active $S$-boxes if $\Delta X_{i} \oplus \Delta X_{i+2} \neq 0$ :

$$
\begin{aligned}
\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}}\right)+\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}+1}\right)+\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}+2}\right) & =\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}}\right)+\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}+2}\right)+\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}+1}\right) \\
& =\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}}\right)+\operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}+2}\right)+\operatorname{Hw}\left(\Delta \mathrm{L}^{-1}\left(\mathrm{Y}_{\mathrm{i}+1}\right)\right)
\end{aligned}
$$

$$
\begin{aligned}
& \geq \operatorname{Hw}\left(\Delta \mathrm{X}_{\mathrm{i}} \oplus \Delta \mathrm{X}_{\mathrm{i}+2} \oplus \Delta \mathrm{~L}^{-1}\left(\mathrm{Y}_{\mathrm{i}+1}\right)\right) \\
& =\operatorname{Hw}\left(\mathrm{L}\left(\Delta \mathrm{~L}^{-1}\left(\mathrm{Y}_{\mathrm{i}+1}\right)\right) \oplus \Delta \mathrm{L}^{-1}\left(\mathrm{Y}_{\mathrm{i}+1}\right)\right) \\
& =5
\end{aligned}
$$

Theorem 3: Any four consecutive rounds of FeW ( $\mathrm{i}^{\text {th }}$ to $\mathrm{i}+3^{\text {rd }}$ round) can have at the most one differentially inactive round function.

Proof: We use the Fig. 3 to prove the theorem. If round function to $\mathrm{i}^{\text {th }}$ round is differentially active then we must have 64-bit input to this round of the form $\left(\Delta \mathrm{P}_{\mathrm{i}} \neq 0\right) \|\left(\Delta \mathrm{P}_{\mathrm{i}+1}=0\right)$, which implies that $\Delta \mathrm{X}_{\mathrm{i}}=0 \& \Delta \mathrm{Y}_{\mathrm{i}}=0$. Number of active S -boxes in this round are zero. Input to $i+1^{\text {th }}$ round will be of the form $\left(\Delta P_{i+1}=0\right) \|\left(\Delta P_{i+2}=\Delta P_{i} \neq 0\right)$, which gives us that $\Delta X_{i+1} \neq 0 \& \Delta Y_{i+1} \neq 0$. Minimum number of active $S$-boxes in this round is 1 . We obtain input to $i+2^{\text {nd }}$ round of the form ( $\left.\Delta P_{i+2}=\Delta P_{i} \neq 0\right) \|\left(\Delta P_{i+3} \neq 0\right)$, which means $\Delta X_{i+2} \neq 0 \& \Delta Y_{i+2} \neq 0$. Minimum number of active S-boxes for this round are 4. For the input ot the round function of $i+3^{\text {rd }}$ round (i.e $\Delta X_{i+3}$ ) to be be differentially passive, we should get input to this round of the form ( $\left.\Delta P_{i+3}=\Delta P_{i} \neq 0\right) \|\left(\Delta P_{i+4}=0\right)$. This type of input ( $\Delta \mathrm{P}_{\mathrm{i}+4}=0$ ) is possible in the case when $\Delta \mathrm{P}_{\mathrm{i}} \oplus \Delta \mathrm{Y}_{\mathrm{i}+2}=0$. Susbstituting this value in terms of input, we get $\Delta \mathrm{P}_{\mathrm{i}} \oplus \mathrm{F}\left(\Delta \mathrm{P}_{\mathrm{i}+3}\right)=0$. Finally, writing $\mathrm{P}_{\mathrm{i}+3}$ in terms of $\Delta \mathrm{P}_{\mathrm{i}+2}$, we get $\Delta \mathrm{P}_{\mathrm{i}} \oplus \mathrm{F}\left(\mathrm{F}\left(\Delta \mathrm{P}_{\mathrm{i}+2}\right)\right)=0$, which can be represented in terms of input to $\mathrm{i}^{\text {th }}$ round as follows:

$$
\Delta \mathrm{P}_{\mathrm{i}} \oplus \mathrm{~F}\left(\mathrm{~F}\left(\Delta \mathrm{P}_{\mathrm{i}}\right)\right)=0
$$

We searched this relation for all possible input differences $\Delta \mathrm{P}_{\mathrm{i}} \neq 0$ using a Computer programme but this relation was not satisfied for any $\Delta P_{i} \neq 0$.

We derived the above results considering the strucure of FeW broadly a Feistel structure, while FeW is based on Fesitel-M structure, which mix the Feistel branches and apply two different functions. We found the minimum number of active S -boxes (Table 3) in each round of FeW with Feistel-M structure. Maximum differential probability of the $4 \times 4$ S-box used in FeW is $2^{-2}$. Table 3 shows that the minimum number of active S -boxes in 11 rounds is 34 , which confirms that single differential charcatersitics is bounded by $2^{-68}$. It is not possible to mount any useful differential attack beyond 16 rounds.

| \#Round | \#Active S-boxes(min) |
| :---: | :---: |
| 1 | 0 |
| 2 | 1 |
| 3 | 5 |
| 4 | 10 |
| 5 | 14 |
| 6 | 17 |
| 7 | 20 |
| 8 | 24 |
| 9 | 27 |
| 10 | 30 |
| 11 | 34 |

Table 3: Number of Active S-boxes

To show full round FeW immune to Differential attack, we provide a lower bound on the number of active S-boxes in 27 round differential charcteristic. The following theorem shows the resistance of full round FeW against the Differential attack.
Theorem 4: Any differential characteristic for 27 rounds of FeW has a minimum 45 active S-boxes and hence the probability of this differential characteristic is $2^{-90}$.

Proof: We can easily prove this using the fact that any 3 round of FeW has a minimum of 5 differentially active S-boxes. Therefore $3 \mathrm{x} 9=27$ rounds will have minimum of $5 \mathrm{x} 9=45$ differentially active S-boxes. So, the probability of a single 27 round differential trail is ( $2^{-}$ $\left.{ }^{2}\right)^{45}=2^{-90}$. If we use 27 round trail to recover round subkeys for 32 round FeW , it will require $2^{90}$ chosen plaintext which is more than the amount of data available. This theorem ensures that full round FeW is secure enough against differential attack.

### 3.2 Impossible Differential Cryptanalysis

Impossbile Differential attack [3] is an extension of basic differential attack This attack works with differentials of probability 0 as opposed to basic differential attack which requires differentials of high probability. This attack recovers keys using impossible differential by dropping the keys from the list of all possible key candidates which satisfies the impossible differntial and the key (or keys) remaning in the list are the candidates for the correct key. This attack has given best result on some ciphers like CLEFIA. We obtain the following best 6 round impossible differential trail for FeW :

$$
(\alpha 00000000000 \text { 0000) 6R } \rightarrow(000000000000 \alpha 000)
$$

where $\alpha$ denote any non zero 4 bit nibble and * denote any 4 bit nibble. We get contradication at round 3 between two events of probability 1 (Table 4). Using this impossible differential trail and allowing the attacker to add 3 round on the top and 6 rounds at the bottom of this trail, on can still break FeW reduced to at the most 15 rounds.

| \#R | 6 R Impossible Differential | $\operatorname{Pr}$ |
| :---: | :---: | :---: |
| 0 | $\alpha 000000000000000$ |  |
| 1 | $00000000 \alpha 0000000$ | 1 |
| 2 | $\alpha 0000000 * * * * 0000$ | 1 |
| 3 | $* * * * 0000 * * * * * * * *$ | 1 |
| 3 | $* * * * * * * * * * * * 0000$ | 1 |
| 4 | $* * * * 0000000 \alpha 0000$ | 1 |
| 5 | $000 \alpha 000000000000$ | 1 |
| 6 | $000000000000000 \alpha$ |  |

Table 4: Impossible Differential trail

### 3.3 Linear Cryptanalysis

FeW can be shown resistant to Linear cryptanalysis [24] similar to the case of resistence to differential attack. First we define Linear Branch number of the linear layer L of FeW :

Definition 3: Linear Branch number $\beta_{l}$ of a function L is defined as:

$$
\beta_{l}(L)=\min _{\alpha \neq 0, \alpha \in\{0,1\}^{16}}\left(H w(\alpha)+H w\left(L^{*}(\alpha)\right)\right.
$$

where $\alpha$ is output mask value and $\mathrm{L}^{*}(\alpha)$ is input mask value to the linear layer . $\mathrm{L}^{*}$ is the linear function concerned to L . In case of FeW , Linear Branch number of the linear layers $L_{1}$ and $L_{2}$ used in $F$ is 5 , which is verified by a Computer programme.

Theorem 4: Any linear characteristic for 27 rounds of FeW has a minimum 45 active Sboxes and hence the maximal bias of this 27 round linear trail is $2^{-90}$.

Proof: We again consider FeW as a Feistel structure only. Linear branch number of linear layers $\mathrm{L}_{1}$ and $\mathrm{L}_{2}$ of FeW is 5 and the maximal bias of the S -box is $2^{-2}$. Any 3 rounds linear trail of FeW has a minimum 5 linearly active S -boxes which can be easily verified (Fig. 3). Any output mask value $\alpha$ to round function F corresponds to input mask value $\beta$ and this becomes output mask value to the next round. If we get $\alpha$ as input mask value again then there are minimum 5 linearly active S -boxes in 3 round linear trail since the branch number of Layer $L$ is 5 .

Fig. 4: Linear trail of FeW (Broadly a Fesitel Structure)
By using Matsui`s [24] Piling-up lemma, we get maximal bias for 3 round linear trail:

$$
2^{4} \times\left(2^{-2}\right)^{5}=2^{-6}
$$

Applying the same lemma again, we get the maximal bias of 27 round linear trail:

$$
2^{8} \times\left(2^{-6}\right)^{9}=2^{-46}
$$

If we assume that full round is attacked using 27 round differential trail, then the amount of known plaintext/ciphertext data requirement is of order $2^{90}$ which is more than the available data limit.

### 3.4 Zero Correlation Cryptanalysis

Zero correlation attack [5] is an extension of linear attack and this is similar to the impossible differential attack which is the extension of differential attack. This attack was published by Bogdanov \& Rijmen and they applied this attack on CLEFIA reduced to 13 rounds using 9 round zero correlation trail. CLEFIA like structures have the maximum 9 round zero correlation trail. But, our design is Feistel-M based design so it is not possible to get even 9 round zero correlation trail for this type of designs. Similar to the impossible differential cryptanalysis of FeW , zero correlation trail for FeW exist ony for 6 rounds and FeW can be attacked using this attack upto the maximum 15 rounds.

### 3.5 Related Key Cryptanalysis

We exploit the weakness of Key schedule in Related key attack[1]. We have designed the Key schedule of FeW in a similar way to the lightweight block cipher PRESENT's Key schedule. Our key schedule is stronger than the Key schedule of PRESENT. We have made 3 application of non linear S-box for each 16-bit subkey derivation. As a result, all subkey bits are nonlinear function of key bits after 11 rounds. Till now, there is no significant attack on PRESENT's key schedule, therefore we assume that this attack can not be applied to FeW which has a stronger key schedule than PRESENT.

## 3. Conclusion

We described a new lightweight block cipher $F e W$ by introducing a new type of mixing between Feistel and generalised Feistel structures based designs. We called this structure a Feistel-M structure which is used for the first time in the design of lightweight block cipher FeW . We analysed the security of FeW against some basic cryptanalytic attacks and this design is secure enough against these attacks. There is a large variety of attacks which can be applied to block ciphers, therefore we invite all researchers to apply and report their attacks on FeW.

## Acknowledgements

The first author would like to thank Dr. PK Saxena, Director SAG for his support and Ms. Pratibha Yadav for her valuable guidance and continuous support to work in this direction. I am thankful to Dr. Dhananjoy Dey for giving his precious time in valuable discussions on design principles \& cryptanalysis and Ms. Noopur Shrotriya for her valuable guidance in computer implementations. I thank Mr. Sohan Lal and Ms. Anita Dwivedi for help in testing the data of Cipher. I also thank Dr. PR Mishra for spending his valuable time in reading the paper and suggesting the useful and important corrections in the paper.

## Appendix B: Key schedule (MK-128)

First, store MK-128 in a key register called MK as MK= $k_{0} k_{1} k_{2} k_{3} \ldots \ldots . . . . k_{127}$. We obtain round subkeys $\mathrm{RK}_{0}$ by extracting leftmost 16 bits of current contents of MK and proceed in the following way to obtain the other round subkeys:
a. While $i<64$, update the register MK in the following steps:
(i) $\mathrm{MK} \lll 13$
(ii) $\left[\mathrm{k}_{0} \mathrm{k}_{1} \mathrm{k}_{2} \mathrm{k}_{3}\right] \leftarrow \mathrm{S}\left[\mathrm{k}_{0} \mathrm{k}_{1} \mathrm{k}_{2} \mathrm{k}_{3}\right]$
$\left[\mathrm{k}_{4} \mathrm{k}_{5} \mathrm{k}_{6} \mathrm{k}_{7}\right] \leftarrow \mathrm{S}\left[\mathrm{k}_{4} \mathrm{k}_{5} \mathrm{k}_{6} \mathrm{k}_{7}\right]$
$\left[\mathrm{k}_{64} \mathrm{k}_{65} \mathrm{k}_{66} \mathrm{k}_{67}\right] \leftarrow \mathrm{S}\left[\mathrm{k}_{64} \mathrm{k}_{65} \mathrm{k}_{66} \mathrm{k}_{67}\right]$
$\left[\mathrm{k}_{76} \mathrm{k}_{77} \mathrm{k}_{78} \mathrm{k}_{79}\right] \leftarrow \mathrm{S}\left[\mathrm{k}_{76} \mathrm{k}_{77} \mathrm{k}_{78} \mathrm{k}_{79}\right]$
(iii) $\left[\mathrm{k}_{68} \mathrm{k}_{69} \mathrm{k}_{70} \mathrm{k}_{71} \mathrm{k}_{72} \mathrm{k}_{73} \mathrm{k}_{74} \mathrm{k}_{75}\right] \leftarrow\left[\mathrm{k}_{68} \mathrm{k}_{69} \mathrm{k}_{70} \mathrm{k}_{71} \mathrm{k}_{72} \mathrm{k}_{73} \mathrm{k}_{74} \mathrm{k}_{75}\right] \oplus[\mathrm{i}]_{2}$
b. Increment $i$ by 1 and extract leftmost 16 bits of current contents of MK as round subkey $\mathrm{RK}_{\mathrm{i}}$.

## Appendix C: Decryption Algorithm (FeW-80)

FeW is balance Feistel-M based design, therefore decryption algorithm of FeW uses the same round function as encryption algorithm. The only difference is that the round subkey is used in reverse direction. Decryption procedure is described as follows:

First we divide 64-bit ciphertext $\mathrm{C}_{\mathrm{m}}$ into two halves of size 32 bit each namely $\mathrm{C}_{0}$ and $\mathrm{C}_{1}$. We have 64-bit input ciphertext $\mathrm{C}_{\mathrm{m}}$ as below:

$$
\mathrm{C}_{0} \| \mathrm{C}_{1} \leftarrow \mathrm{C}_{\mathrm{m}}
$$

Decryption procedure of FeW is expressed as follows:
(a) For i $=0$ to 31 , apply round functions F on 32 -bit word $\mathrm{C}_{\mathrm{i}+1}$ and xor it with $\mathrm{C}_{\mathrm{i}}$ to produce $\mathrm{C}_{\mathrm{i}+2}$

$$
\mathrm{C}_{\mathrm{i}+2} \leftarrow \mathrm{C}_{\mathrm{i}} \oplus \mathrm{~F}\left(\mathrm{C}_{\mathrm{i}+1} \oplus \mathrm{~K}_{31-\mathrm{i}}\right)
$$

(b) Finally, apply the following swap function on the output of last round

$$
\left(\mathrm{C}_{33}, \mathrm{C}_{32}\right) \leftarrow\left(\mathrm{C}_{32}, \mathrm{C}_{33}\right)
$$

(c) We obtain the following 32 bit plaintext words $\mathrm{P}_{0}$ and $\mathrm{P}_{1}$ :

$$
\left(\mathrm{P}_{0}, \mathrm{P}_{1}\right) \leftarrow\left(\mathrm{C}_{33}, \mathrm{C}_{32}\right)
$$

We obtain the 64-bit plaintext as concatenation of two 32 bit words $\mathrm{P}_{0}$ and $\mathrm{P}_{1}$ as follows:

$$
\mathrm{P}_{\mathrm{m}} \leftarrow \mathrm{P}_{0} \| \mathrm{P}_{1}
$$
