

Lighter, Faster, and Constant-Time: WhirlBob, the Whirlpool variant of StriBob

Markku-Juhani O. Saarinen

Norwegian University of Science and Technology
mjos@item.ntnu.no

Abstract. WhirlBob is an Authenticated Encryption with Associated Data (AEAD) algorithm derived from the first round CAESAR candidate StriBob and the Whirlpool hash algorithm. As with StriBob, the reduced-size Sponge design has a strong provable security link with a standardized hash algorithm. The new design utilizes only the LPS or ρ keying line of Whirlpool in a flexible domain-separated BLNK Sponge mode and adds the number of rounds in π permutation from 10 to 12 as a countermeasure against Rebound Distinguishing attacks. One of the main advantages of WhirlBob over StriBob is its greatly reduced implementation footprint on resource-constrained platforms. Remarkably, the entire C reference implementation of WhirlBob 1.0 π fits onto a single page of the Appendix. On many low-end microcontrollers the total software footprint of π +BLNK = WhirlBob AEAD is less than half a kilobyte. We also report an FPGA implementation of WhirlBob. The implementation requires 4,946 logic units for a single round of WhirlBob, which compares favorably to 7,972 required for Keccak/Keyak on the same platform. The relatively small hardware gate count is also reflected as efficient bitsliced straight-line implementations, especially on 64-bit platforms. Bitslicing is an efficient countermeasure against AES-style cache timing side-channel attacks. Our constant-time bitsliced implementations run at around 35 % of the speed of 64-bit table-lookup implementations. We finally present some discussion and analysis on the relationships between Whirlpool, the Russian GOST Streebog hash, and the recently proposed draft Russian Encryption Standard Kuznyechik.

Keywords: Authenticated Encryption, Sponge designs, Whirlpool, Streebog, StriBob, CAESAR Project.

1 Introduction

WhirlBob 1.0 is an Authenticated Encryption with Associated Data (AEAD) algorithm based on the CAESAR candidate StriBob [49, 50] and NESSIE Final Portfolio [36] hash function Whirlpool 3.0 [4]. AEAD algorithms and modes such as GCM [39] provide both confidentiality and integrity protection in a single pass, thus eliminating the requirement for an MAC algorithm such as HMAC [40]. This has clear advantages for performance and implementation footprint. Extensible-Output Functions (XOFs) such as SHA3 SHAKE [41] offer similar features to AEADs in some Sponge modes [11, 12].

Fig. 1. A simplified view of a Sponge-based AEAD. Padded Secret Key, Nonce, and Associated Authenticated Data - all represented by d_u words - are first “absorbed” into the state. The π permutation is then also used to encrypt data p_i into ciphertext c_i (or vice versa) and finally to “squeeze” out a Message Authentication Code h_i .

2 Motivation: Security Goals and Parameters

WhirlBob uses StriBob’s versatile BLNK Sponge AEAD mode without modification. Outside the CAESAR context, BLNK can be also used in a wider set of applications, even to build entire secure lightweight protocol suites [47].

A sponge mode requires only a single cryptographic component; an unkeyed cryptographic permutation π (See Figure 1). As with other provable Sponge modes, we assume that π is indistinguishable from a random permutation. This work focuses on π permutation design – for BLNK padding details and analysis we refer to [26, 47, 50].

After close examination it is clear that the Russian GOST hash standard Streebog [22] was closely modeled after Whirlpool [4]. StriBob and WhirlBob only differ in the particular numerical selections for the round constants C_i , the 8 - bit S-Box S , byte permutation P , and the 8×8 MDS matrix L , which is defined over a finite field $GF(2^8)$. These components, $L \circ P \circ S$ or the “LPS permutation” is derived almost unmodified from that of Whirlpool for WhirlBob. Both StriBob and WhirlBob have 12 rounds and the same state size.

The aim is to allow the same secure LPS implementation core (such as a special instruction of a SoC CPU in a mobile or IoT device) to be used for unkeyed hashing according to the Whirlpool standard. This is useful in applications such as certificate processing. The corresponding standardized, Miyagushi-Preneel hash functions require two (or more) times as much as state and processes data in bigger chunks. Our BLNK Sponge mode naturally also supports hashing and MACing without encryption. The Sponge variants are slightly faster.

All of security parameters remain unmodified from StriBob. As with StriBob, we have an $b = 512$ bit state, which is split to $r = 256$ - bit *rate* “block size” and $c \approx 254$ - bit *capacity*, which is the secret state. According to Theorems such as those given in [26, 50] show that this is sufficient for $k = 192$ - bit secret key security level when less than 2^{64} bits are processed under same key and nonce pair. Nonce size is largely arbitrary, but in the standard variant we adopt $n = 128$ bits. See Section 4 for further security analysis.

3 WhirlBob

Despite having almost equivalent speed and size on typical 64-bit platforms, the size and performance characteristics of StriBob and WhirlBob differ significantly in hardware, low-end microcontrollers, and in bitslicing implementations. We therefore suggest using WhirlBob especially in those cases.

We give an abbreviated description of WhirlBob’s 512×512 - bit keyless π permutation as the computation follows exactly the operation of the internal key schedule of Whirlpool 3.0 [4]. The only modification is that the number of rounds is increased from $R = 10$ to $R = 12$. The key schedule operation is effectively equivalent to the “internal block cipher” W . Blocks of eight bytes from the S-Box are used as partial round keys C_i , as in WhirlPool.

WhirlBob’s permutation π is indeed highly similar to AES. In case of StriBob, the “Russian 512-bit block AES” permutation had to be laboriously uncovered from the structure (See Section 4.3), but the particularities and history of Whirlpool make the connection immediately obvious.

The 512-bit state is typically written as a matrix of 8×8 bytes. To compute $\pi(x_0) = x_{12}$ we iterate

$$x_{i+1} = L(P(S(x_i))) \oplus C_i$$

where, if we use the original AES-style notation, S is equivalent to `SubBytes`, P corresponds to `ShiftColumns`, L to `MixRows`, followed by `AddRoundKey`.

3.1 Lightweight Reference Implementation

The entire byte-oriented implementation of π fits onto a single page; See Appendix A. Remarkably, in addition to π , only the S-Box `wbob_sbox[256]` (See Section 3.2) together with minimal BLNK logic are required for full AEAD implementation. On most microcontrollers WhirlBob’s entire software footprint is in the 500B range. Slightly more is required for a shared secret handshake protocol and two-way secure BLINKER protocol [47].

This is a significant improvement over StriBob, which typically needs almost 2kB. StriBob is also much slower and larger on low-end microcontrollers due to the “heavy” MDS matrix. The reference implementation is written for compactness and clarity; it is not optimal when it comes to speed or size. We refer to section 7.3 of [4] for techniques that greatly reduce the number of XORs required, resulting in increased processing speed. Additional tables will be required and this will increase the overall implementation size.

Whirlpool ISO Standard trace test vectors have been used to verify the correctness of this π implementation, up to $R=10$ (Appendix B). One simply observes the keying “line” of these traces and ignores the encryption “line”. We offer the listing of Appendix A as WhirlBob v1 π Reference implementation (Please note the system of algorithm designations at the end of Section 5.)

Table 1. Three 4×4 miniboxes that are used to build the 8×8 S-Box in Whirlpool and WhirlBob 1.0. We may revise these for CAESAR Round 2.

x	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
$E(x)$	1	B	9	C	D	6	F	3	E	8	7	4	A	2	5	0
$E^{-1}(x)$	F	0	D	7	B	E	5	A	9	2	C	1	3	4	8	6
$R(x)$	7	C	B	D	E	4	9	F	6	3	8	A	2	5	1	0

3.2 Impact of New S-Box Structure on Implementations

Whirlpool’s S-box design utilizes three 4×4 - bit “miniboxes” given in Table 1: E , E^{-1} , and R . Figure 2 shows how these are used to construct the 8×8 - bit S-Box. This computation can even be performed on the fly on 4-bit microcontrollers.

FPGA implementations save a significant number of LUTs by explicitly utilizing the 4-bit structure rather than implementing a general 8×8 lookup table.

The byte-oriented $8 \times 64 = 512$ - bit state can be rapidly split into eight 64-bit registers (the first register representing the bit 0 of each one of the 64 bytes etc). This bitsliced mode can be maintained for the entire 12-round computation as there is no external input to the keyless permutation.

The parallelism evident in Figure 2 helps to speed up bitsliced implementation. We see that for 2/3 of the time, the S-Box has effectively two independent 4-bit execution paths. Interleaving these may greatly reduce wait states due to the superscalar architecture employed by most modern CPUs. Execution time of a bitsliced software implementation is therefore not linearly dependent on the number of instructions.

Fig. 2. The 8×8 - bit S-box is constructed from 4×4 - bit “miniboxes”.

Table 2. Comparing software implementations of WhirlBob’s π on a single core of 2.8GHz Core i7 860. No architecture-dependent intrinsics or techniques are used.

Metric	Throughput (Mbytes/sec)	Footprint (code+data bytes)	Source Code (lines, w.o. tables)
8-bit C99 Reference	4.6311	326 + 256	97
64-bit C99 Reference	95.368	1942 + 16512	128
Bitsliced C99 Reference	30.856	4592 + 758	345
Intel SSSE3 Intrinsics	123.15	1290 + 1152	307

3.4 Comparison with Other AEAD Schemes.

At the time of writing (Q3/2014) the dominant AEAD scheme is the Galois / Counter Mode (GCM) for the AES block cipher [37, 39], which is recommended for use with TLS, SSH and IPSec protocols by NSA as part of “Suite B” [17, 23, 42, 51]. GCM message authentication is based on polynomial evaluation in the finite field $\text{GF}(2^{128})$. The required multiplication can be exceedingly slow on lightweight platforms. An LFSR-style implementation of a 128×128 - bit multiplication will require thousands of cycles on 8-bit targets.

It is often be more efficient to use the CCM [38, 55] double-mode of operation on lightweight platforms, since implementing a full extra AES operation can be faster than the finite field multiplication operation. CCM and GCM are currently the only two FIPS - standardized authenticated modes. The performance characteristics of AES-CCM AEAD can be expected to very similar to WhirlBob due to their structural similarities and relative data bandwidth:

- WhirlBob: 12 rounds with 64 S-Boxes for 256 bits of data.
- AES-192-CCM: 2×12 rounds with 16 S-Boxes for 128 bits of data.

There are additional (patented) AES modes which will be faster on 8-bit platforms – such as AES-OTR [34] and AES-OCB [28], and dozens of others. Virtually all block cipher modes offer lower levels of integrity protection (2^{64} level even for 128-bit tags) and are not directly usable in wider Sponge applications such as non-randomized hashing.

At the time of writing (Q3/2014) only unoptimized reference implementations are available for most CAESAR candidates [18], making fair performance comparisons difficult. Furthermore, no other CAESAR candidate is targeted at 192-bit security level apart from AES modes. Little attention has been paid to 8-bit or hardware implementations, and the speed difference between some “reference” and “target optimized” implementations can be several orders of magnitude.

We note that leading full-featured Sponge candidates, directly SHA3 / Keccak - based Ketje [11] and Keyak [12] have significantly slower reference implementation than StriBob and Whirlbob (Table 3). WhirlBob falls very significantly from candidates such as NORX [3] and MORUS [56], which have been specifically designed for 64-bit targets. Our proposal can claim a more conservative security margin when compared to these candidates, however.

Table 3. Relative performance of some CAESAR candidates on the “Titan” AMD64 reference system in SUPERCOP testing (smaller number indicates faster speed).

MORUS 1280 - 128 [56]	0.09
NORX 64-4-1 [3]	0.19
ASCON-128n [21]	0.89
WhirlBob Intel SSSE3	1.00
WhirlBob and StriBob 64-bit Reference	1.26
Lake Keyak [12]	2.23
Ketje Sr. [11]	4.25
PRIMATES (HANUMAN, GIBBON, APE) [2]	50+

4 Security Analysis and Design Notes

Most of the security arguments and proofs offered for StriBob in [50] also apply unmodified to the new proposal, as those proofs are based on an indistinguishably arguments of the π permutation and a simple theorem (Thm. 1, Sec. 3.3. in [50]) that loosely ties the Miyagushi-Preneel mode [35, 45] with the indistinguishably of π . A random-indistinguishable π and appropriate padding rules are sufficient to construct Sponge-based hashes [6], Tree Hashes [10], MACs [9], Authenticated Encryption (AE) algorithms [8, 12], and pseudorandom extractors (SHAKEs, PRFs, and PRNGs) [7, 41].

4.1 Side-Channel and Implementation Attacks

Whirlpool is better suited for bitsliced implementation due to its particular S-Box and MDS design (as noted in Section 3.2). As an unconditional straight-line code without data-dependent table lookups, a bitsliced implementation is an effective countermeasure against cache timing attacks, which have been found to be effective against cryptographic primitives with large tables such as AES [1, 5, 44, 54].

A non-bitsliced implementation of the S-Box on Whirlpool, Streebog, or StriBob on 64-bit platforms typically requires lookup tables of up to $8 \times 256 \times 8 = 16384B$. Even though this size easily fits into the Level 2 cache of any 64-bit system, one may see that timing attacks are possible as L2 caches are not always shared even between different execution cores within a single CPU unit. This is due to the process switching operation of most 64-bit operating systems.

4.2 Historical Modifications to Whirlpool

Whirlpool has received a significant amount of analysis in the almost 15 years since its original publication. Whirlpool was the only hash function in the final NESSIE portfolio in addition to SHA-2 hashes [36]. Whirlpool has also been standardized by ISO as part of ISO/IEC 10118-3:2004 [24].

Our design is based on Whirlpool 3.0. The amended MDS matrix used by current ('03) Whirlpool is also used by WhirlBob as a countermeasure to the structural observations given in [52].

Whirlpool was found to be vulnerable to a Rebound Distinguisher [29, 30, 33]. That 2^{188} attack applies to the 10-round variant; our 12-round version should offer a comfortable security margin, especially as our security target is 2^{192} . The way the round constants are derived from the S-Box allows this change to be made in a straightforward manner.

4.3 Notes on the origins of Streebog, Kuznyechik, and StriBob

The GOST R 34.11-2012 “Streebog” standard text [22] does not describe the linear step as a 8×8 matrix-vector multiplication with $\text{GF}(2^8)$ elements like the StriBob spec [50], but as a 64×64 binary matrix multiplication. One can see that $8 \times 8 \times 8 = 512$ bits are required to describe the former, but $64 \times 64 = 4096$ bits are required for the latter. The more effective description was discovered by Kazymorov and Kazymorova in [27] by exhaustively testing all 30 irreducible polynomial basis, revealing an AES-like MDS structure. The origin of the particular numerical values of that MDS matrix and round constants is still a mystery. They do not appear to offer avenues for size or performance optimization like those in Whirlpool 3.0 and WhirlBob do.

The 8-bit S-Box used by StriBob was directly lifted from Streebog so that hardware and software components developed for Streebog could be shared or recycled when implementing StriBob. The same S-Box is also used by the very recently proposed Russian Encryption Standard “Kuznyechik” [53].

Not much about the particular design criteria of the Streebog S-Box has been published. That S-box was apparently selected at least 5 years ago as Streebog already appeared in RusCrypto '10 proceedings [32]. We can easily observe that it offers reasonable resistance against basic methods of cryptanalysis. Its differential bound [13] is $P = \frac{8}{256}$ and best linear approximation [31] holds with $P = \frac{28}{128}$. There does not seem to be any exploitable algebraic weaknesses. These are the exactly same bounds as can be found for Whirlpool S-Box, but fall clearly short from the bounds of the AES S-Box.

The Rijndael AES S-box is constructed of from finite field inversion x^{-1} operation in $\text{GF}(2^8)$ (inspired by the Nyberg construction [43]) and an affine bit transform that serves as a countermeasure against, among other things, Interpolation Attacks [25] on AES' predecessor SHARK [46]. We refer to [20] for more information about the AES design process.

The author had brief informal discussions with some members of the Streebog and Kuznyechik design team at the CTCrypt '14 workshop (05-06 June 2014, Moscow RU). Their recollection was that the aim was to choose a “randomized” S-Box that meets the basic differential, linear, and algebraic requirements. Randomization was simply iterated until a “good enough” permutation was found. This was seen as an effective countermeasure against yet-unknown attacks. At the time of Streebog S-Box selection (before 2010's) the emergence of allegedly effective AES Algebraic Attacks such as [19] was a major concern for much of the

symmetric cryptographic community. Hence it was felt appropriate to avoid too much algebraic structure in either the S-Box or MDS matrix while also ensuring necessary resistance against known attacks such as DC and LC. Algebraic attack attempts of this type against AES have since largely fizzled out, so we feel confident that the Whirlpool S-Box should be sufficient for our claimed security level, especially as it offers significantly better speeds in bitsliced implementations.

One is left with the impression that Streebog is a “whitened” or randomized copy of the original Whirlpool design. Despite its partially unknown origins and relative shortcomings on some implementation targets, we consider StriBob to be a more secure algorithm than WhirlBob if appropriately implemented. Indeed some of the more successful attacks on AES and Whirlpool have been based on their deep structural self-similarities and simplistic key schedules [14–16].

5 Conclusions

We have introduced the WhirlBob 1.0 authenticated encryption algorithm, a variant of the StriBob first round CAESAR candidate. The new proposal loans its key components from the Whirlpool 3.0 hash function, modifying it into a Sponge AEAD. WhirlBob has extremely small implementation footprint on resource-limited software and hardware platforms – typically under half a kilobyte. The reference implementation fits onto a single page of Appendix A.

The hardware-optimized design of Whirlpool components also gives WhirlBob efficient bitsliced implementation. A bitsliced implementation is an effective countermeasure against cache timing attacks, which have been a concern against AES. The $b = 8 \times 64$ - bit state size is particularly suitable for bitslicing of an byte-oriented algorithm on 64-bit platforms.

We also discussed the design choices for the S-Box and other components used in the Streebog hash and Kuznyechik cipher, which are standards or becoming standards for the Russian security market. StriBob uses this S-Box as well, and we feel that it offers better long-term security than Whirlpool, if appropriately implemented.

However WhirlBob has superb implementation characteristics on lightweight platforms and offers provable security assurance through its security reduction to the well-analyzed Whirlpool hash. Furthermore, the RAM requirement of WhirlBob AEAD is only half of that required by Whirlpool.

Note on designations. This document describes WhirlBob 1.0, which corresponds to Whirlpool 3.0’s components. Should STRIBOB be selected for the second round of the CAESAR competition, a WhirlBob tweak will be designated STRIBOBr2d2 (Round 2, Design 2) a.k.a. WhirlBob 2.0 and may differ from this description. The original StriBob based on Streebog components will be designated STRIBOBr2d1 (Round 2, Design 1.) The current official first round algorithm designation is STRIBOBr1 [50].

Acknowledgements

We thank Billy Brumley (Tampere University of Technology) for help with NEON and SSE3 implementations. The author wishes to also thank Oleksandr Kazymyrov, Vasily Shishkin, Bart Preneel, and Paulo Barreto for their helpful comments. This work was carried out during the tenure of an ERCIM “Alain Bensoussan” Fellowship Programme.

A WhirlBob 1.0 π “8-bit” Reference Implementation

This ANSI C function implements the WhirlBob 512×512 -bit π permutation.

```
void wbob_pi(uint8_t st[64]) // WhirlBob Pi
{
    int r, i, j;
    uint8_t t[64], x, *pt;

    for (r = 0; r < 12; r++) { // 12 rounds
        for (i = 0; i < 64; i++) {
            t[(i & 7) + ((i + (i << 3)) & 070)] = // P
                wbob_sbox[st[i]]; // S
        }
        // The round constants C comes from the S-box
        pt = (uint8_t *) &wbob_sbox[8 * r];
        for (i = 0; i < 8; i++)
            st[i] = pt[i]; // C in first 8
        for (i = 8; i < 64; i++)
            st[i] = 0; // zero the rest

        // Apply the circular, low weight MDS matrix
        for (i = 0; i < 64; i += 8) {
            pt = &st[i]; // start of row
            for (j = 0; j < 8; j++) {
                x = t[i + j]; // Circular MDS
                pt[j & 7] ^= x; // 01
                pt[(j + 1) & 7] ^= x; // 01
                pt[(j + 3) & 7] ^= x; // 01
                pt[(j + 5) & 7] ^= x;
                pt[(j + 7) & 7] ^= x;
                // x <- 02
                x = (x << 1) ^ (x & 0x80 ? 0x1D : 0x00);
                pt[(j + 6) & 7] ^= x; // 02
                // x <- 04
                x = (x << 1) ^ (x & 0x80 ? 0x1D : 0x00);
                pt[(j + 2) & 7] ^= x; // 04
                pt[(j + 5) & 7] ^= x; // 01 + 04 = 05
                // x <- 08
                x = (x << 1) ^ (x & 0x80 ? 0x1D : 0x00);
                pt[(j + 4) & 7] ^= x; // 08
                pt[(j + 7) & 7] ^= x; // 01 + 08 = 09
            }
        }
    }
}
```

B Test Vectors

B.1 The 12-round π transform

These are derived from ISO Test vectors of Whirlpool 3.0. We give the input x_0 and results after 1, 10 (as in Whirlpool), and full 12 rounds of processing.

$$\begin{aligned}
 x_0 &= \begin{pmatrix} 77 & 38 & E1 & B5 & 41 & A0 & 36 & EA \\ 45 & 8D & 50 & F8 & 0F & A0 & 1C & 44 \\ 72 & 88 & CE & 97 & D1 & A0 & DC & F0 \\ 16 & 95 & FF & D6 & E7 & 1D & 09 & 25 \\ 33 & BE & 30 & 9F & 01 & 2A & 59 & 09 \\ 72 & 91 & 14 & 59 & 5F & 08 & 6E & 76 \\ 07 & 18 & AF & E3 & 65 & BC & 09 & DE \\ B6 & AF & A1 & 80 & BC & EC & 2A & 98 \end{pmatrix} & x_1 = \begin{pmatrix} 1A & 78 & 4D & 7D & BD & 4C & 17 & E6 \\ 27 & 31 & 10 & AA & 63 & C5 & 9E & 25 \\ 7A & 2E & B7 & 48 & C4 & 5D & E0 & 23 \\ 6D & 0D & 61 & 9F & 6C & 1D & 80 & AE \\ 01 & A2 & D5 & 6E & DB & 41 & D9 & A0 \\ E9 & 06 & 4C & D1 & 27 & 95 & FA & 86 \\ 77 & 62 & 31 & BC & B4 & 4E & C6 & 01 \\ 6F & CD & BC & 98 & 10 & 78 & 6F & EC \end{pmatrix} \\
x_{10} &= \begin{pmatrix} B4 & 74 & E1 & 56 & 96 & 31 & B9 & 6C \\ 21 & A1 & B6 & 33 & CC & 89 & 68 & 1A \\ B1 & 97 & 25 & 86 & 7B & 2B & 3F & 09 \\ 4C & 73 & C7 & 62 & 93 & A8 & 15 & CF \\ 55 & 15 & C0 & C0 & 9A & 05 & 05 & 16 \\ 23 & 44 & 8D & 8D & D3 & 5F & B3 & 6E \\ 7E & 6C & 2D & 37 & 12 & D0 & F3 & 3E \\ CE & B8 & 04 & F2 & 8D & 9F & C9 & 99 \end{pmatrix} & x_{12} = \begin{pmatrix} 3F & 72 & C2 & 60 & EE & 28 & EF & EA \\ 42 & 8E & B5 & 3A & FB & 8A & 33 & A2 \\ 03 & E4 & 72 & 31 & 90 & A5 & 1A & D3 \\ 3E & 68 & E6 & 46 & FC & 94 & 3C & C7 \\ 80 & 42 & 9E & 2E & CB & 32 & 75 & 93 \\ 30 & AA & E2 & 21 & 21 & C8 & 99 & ED \\ 86 & 1E & 06 & 9E & 91 & 1F & 89 & 6C \\ D2 & 99 & EC & 7E & E9 & 0B & 01 & 10 \end{pmatrix}
 \end{aligned}$$

The last entry corresponds to the final output $\pi(x_0) = x_{12}$.

B.2 Authenticated Encryption

Inputs are plain ASCII.

```

K = "192-bit Secret Key value"           (24 Bytes)
N = "Nonces Used Once"                   (16 Bytes)
A = "AAD Test Vector Exact Block 32 B"   (32 Bytes)
P = "2 Block Test Vector for stribob192r2d2" (38 Bytes)

```

Authenticated ciphertext has 38 message bytes + 16 for MAC = 54 (0x36) bytes:

```

  x0 x1 x2 x3  x4 x5 x6  x7 x8 x9 xA xB  xC xD xE xF
C = 59 9C 5F 69  7F 16 30 07  B4 D5 52 30  24 0C 2B 7B |0x
    0A 93 4E 4C  63 19 4F AC  EA 2D D5 4E  BD 05 61 2C |1x
    19 92 47 FC  A1 97 AE AE  71 0F 0D ED  3E 56 5B D0 |2x
    26 FE 20 F6  4A 4F

```

For BLNK padding technical implementation details, see [50].
