# Low Space Complexity CRT-based Bit-Parallel $G F\left(2^{n}\right)$ Polynomial Basis Multipliers for Irreducible Trinomials 

Jiajun Zhang and Haining Fan

#### Abstract

By selecting the largest possible value of $k \in(n / 2,2 n / 3]$, we further reduce the AND and XOR gate complexities of the CRT-based hybrid parallel $G F\left(2^{n}\right)$ polynomial pasis multipliers for the irreducible trinomial $f=u^{n}+u^{k}+1$ over $G F(2)$ : they are always less than those of the current fastest parallel multipliers - quadratic multipliers, i.e., $n^{2}$ AND gates and $n^{2}-1$ XOR gates. Our experimental results show that among the 539 values of $n \in[5,999]$ such that $f$ is irreducible for some $k \in[2, n-2]$, there are 317 values of $n$ such that $k \in(n / 2,2 n / 3]$. For these irreducible trinomials, the AND and XOR gate complexities of the CRT-based hybrid multipliers are reduced by $15.3 \%$ on average. Especially, for the 124 values of such $n$, the two kinds of multipliers have the same time complexity, but the space complexities are reduced by $15.5 \%$ on average. As a comparison, the previous CRT-based multipliers consider the case $k \in[2, n / 2]$, and the improvement rate is only $8.4 \%$ on average.

## I. Introduction

Low complexity multipliers are key modules of $G F\left(2^{n}\right)$-based cryptographic chips. Their theoretical space and time complexity, namely, the total number of 2-input AND/XOR gates (the $G F(2)$ multiplication/addition) and their corresponding gate delays (denoted by " $T_{A}$ " and " $T_{X}$ "), depend on various factors, for example, the method to represent field elements: polynomial, normal and dual bases; the underlying multiplication algorithms: quadratic and subquadratic algorithms etc. Pure quadratic and subquadratic multipliers are of great theoretical importance. They have the lowest time and space complexities respectively, but their disadvantages are
also obvious: the largest space and time complexities respectively. On the other hand, hybrid approaches in [1], [2] and [3] provide a trade-off between the time and space complexities. These multipliers first perform a few subquadratic iterations to reduce the whole space complexities, and then one quadratic step on small input operands to achieve lower time complexity. Therefore, this hybrid approach is often adopted in practical applications.

Recently, two different hybrid multipliers are presented in [4] and [5]. The former uses the matrix representation, and adopts the " 1 -quadratic-and-then-subquadratic" computational mode. This method reduces the total space complexity for current ASIC implementations. The latter uses the polynomial representation, and follows the " 1 -subquadratic-and-then-quadratic" computational mode first proposed in [6]. Thanks to the property of the ceiling function " $\lceil\cdot\rceil$ ", the time complexity of this multiplier matches the fastest bit-parallel multiplier - the quadratic multiplier - when $u^{n}+u^{k}+1$ is irreducible for some $k \in[(n-1) / 3, n / 2]$. Its highlight is the AND and XOR space complexities: the following bounds of the fastest bit-parallel multipliers were broken for the first time:

$$
\begin{cases}\text { \# AND gates: } & n^{2} \\ \text { \# XOR gates: } & n^{2}-1\end{cases}
$$

In this work, we report a further reduction of the space complexities obtained in [5] for some irreducible trinomials $u^{n}+u^{k}+1$ where $k \in(n / 2,2 n / 3]$. Before explaining our motivation, we recall the multiplier in [5] first.

Let $f(u)=u^{n}+u^{k}+1(n>2)$ be an irreducible trinomial of degree $n$ over $G F(2)$. All elements of the finite field $G F\left(2^{n}\right):=G F(2)[u] /(f(u))$ can be represented using a polynomial basis $\left\{x^{i} \mid 0 \leq i \leq n-1\right\}$, where $x$ is a root of $f$. Given two field elements $a(x)=\sum_{i=0}^{n-1} a_{i} x^{i}$ and $b(x)=\sum_{i=0}^{n-1} b_{i} x^{i}$, where $a_{i}, b_{i} \in G F(2)$, the classical polynomial basis multiplication algorithm computes the $G F\left(2^{n}\right)$ product $c(x)=\sum_{i=0}^{n-1} c_{i} x^{i}$ of $a(x)$ and $b(x)$ using the following two steps. For the sake of simplicity, we omit " $(x)$ " in polynomial " $a(x)$ " and denote $a(x)$ by $a$.
(i) Conventional polynomial multiplication:

$$
s=a \cdot b=\sum_{t=0}^{2 n-2} s_{t} x^{t}
$$

where

$$
s_{t}=\sum_{\substack{i+j=t  \tag{1}\\ 0 \leq i, j<n}} a_{i} b_{j}= \begin{cases}\sum_{i=0}^{t} a_{i} b_{t-i}, & 0 \leq t \leq n-1, \\ \sum_{i=t+1-n}^{n-1} a_{i} b_{t-i}, & n \leq t \leq 2 n-2 .\end{cases}
$$

(ii) Reduction $\bmod f=x^{n}+x^{k}+1$ :

$$
\begin{equation*}
c=\sum_{i=0}^{n-1} c_{i} x^{i}=s \bmod f \tag{2}
\end{equation*}
$$

The product $c$ obtained in the second step is the remainder of $s$ divided by $f$, i.e.,

$$
s=f \cdot q+c
$$

In order to apply the Chinese Remainder Theorem (CRT) in the second step, mutipliers in [5] adopt the following identity:

$$
\begin{equation*}
s=f \cdot q+c=(f+1) q+(c+q) . \tag{3}
\end{equation*}
$$

We note that addition and subtraction are the same in fields of characteristic 2.
This identity converts the seemingly unbreakable step (ii) "modulo the degree- $n$ irreducible trinomial $f$ " into the following two problems:
(A). Compute the quotient $q$ of $s$ divided by $f+1$;
(B). Compute the remainder $(c+q)$ of $s$ divided by $f+1$.

Then the product $c$ of elements $a$ and $b$ can be constructed by $c=q+(c+q)$.
Because the degree- $n$ polynomial $f+1=x^{n}+x^{k}$ is clearly reducible, the CRT can be used to devide problem (B), i.e., $a \cdot b \bmod \left(x^{n}+x^{k}\right)$, into the following two smaller subproblems [5]:
(B.1). $a \cdot b \bmod x^{k}$;
(B.2). $a \cdot b \bmod \left(x^{n-k}+1\right)$.

Thus the product $c$ of elements $a$ and $b$ is now devided into three problems: (A), (B.1) and (B.2). In order to understand the advantage of this method, we make a rough estimate of the AND (or XOR) gate complexities of these three problems. We consider only the quadratic part and ignore the linear part. From the analysis in [5], these three complexities are $C_{\mathrm{A}}=n^{2} / 2$, $C_{1}=k^{2} / 2$ and $C_{2}=(n-k)^{2}$ respectively. Fig 1 (a) and Fig 1 (b) illustrate them for the two special cases $k=n / 3$ and $k=n / 2$ respectively. For the case $k=n / 3$, the summation of $C_{\mathrm{A}}+C_{1}+C_{2}$ is $n^{2}$, which is approximately equal to the AND (or XOR) gate complexity of the fastest quadratic multiplier. In fact, mutipliers in [5] are not better than the best quadratic multipliers for the case $0<k \leq n / 3$. However, for the case $k=n / 2$, this summation is only $7 n^{2} / 8$, which is the best case discussed in [5].

Now we explain our motivation. The CRT divides the size-n problem (B) into two smaller subproblems (B.1) and (B.2) of sizes $k$ and $n-k$ respectively. According to the balancing

Fig. 1. Approximate AND (or XOR) gate Complexities
principle of the algorithm design, it is better to select $k$, if possible, such that the difference between sizes of subproblems (B.1) and (B.2), i.e., $|k-(n-k)|=|2 k-n|$, is as small as possible. Mutipliers in [5] just follow this principle, and select the largest possible $k$ in the range of $[1, n / 2]$ as the best candidate. In fact, the time complexities of other quadratic multipliers are often functions of $k$ too. For a given value of $n$, it is, therefore, better to select some optimal value of $k$ if it is possible. For example, XOR gate delays of the shifted polynomial basis multiplier in [7] and the polynomial basis Montgomery in [8] are as follows:

$$
\begin{cases}\left\lceil\log _{2}(n+k)\right\rceil, & 2 k>n \\ \left\lceil\log _{2}(2 n-k-1)\right\rceil, & 2 k<n\end{cases}
$$

Because a polynomial is irreducible iff its reciprocal polynomial is irreducible, the optimal value of $k$ is just the one that $|k-n / 2|$, or equivalently $|2 k-n|$, is minimal for these multipliers.

But a more careful observation shows that the function

$$
C_{\mathrm{A}}+C_{1}+C_{2}=n^{2} / 2+k^{2} / 2+(n-k)^{2}
$$

namely, the approximate AND (or XOR) gate complexities of the CRT-based multiplier, reaches its minimal value when $k=2 n / 3$, i.e., Fig 1 (c). Therefore, we consider multipliers based on irreducible trinomial $f=u^{n}+u^{k}+1$ for the case $n / 2<k \leq 2 n / 3$ in this work. Our experimental results show that among the 539 values of $n$ such that $4<n<1000$ and $u^{n}+u^{k}+1$ is irreducible over $G F(2)$ for some $k>1$, the proposed multipliers beat those in [5] for 122 values of $n$ : they have the same time complexity, but the space complexities are reduced by $8.4 \%$ on average.

In the following, we first derive explicit formulae of $c=a b$ for the case $n / 2<k \leq 2 n / 3$ and then compare their complexities with previous multipliers.

## II. The Expression of $c=a b \in G F\left(2^{n}\right)$ FOR $n / 2<k<2 n / 3$

In this section, we consider the case $n / 2<k<2 n / 3$. The special case $k=2 n / 3$ will be discussed later because its expression is different slightly. We first derive the expressions of the quotient and the remainder of $s=a \cdot b$ divided by $(f+1)=x^{n}+x^{k}$, and then present the expression of $c=a b$ in $G F\left(2^{n}\right)$.
A. Compute the quotient $q$ of $s=a \cdot b$ divided by $(f+1)=x^{n}+x^{k}$

Since $\operatorname{degree}(q) \leq n-2$ in (3), we can define $q$ as $q:=\sum_{i=0}^{n-2} q_{i} x^{i}$. Replacing $f$ in (3) by $f=x^{n}+x^{k}+1$, we have

$$
s=(f+1) q+(c+q)=q \cdot x^{n}+q \cdot x^{k}+(c+q) .
$$

It is clear that

$$
\begin{equation*}
q_{i}=s_{i+n}, \text { for } k-1 \leq i \leq n-2 . \tag{4}
\end{equation*}
$$

Moreover, we have $s_{i+n}=q_{i}+q_{i+n-k}$ for $2 k-1-n \leq i \leq k-2$. The terms $q_{i+n-k}$ for $2 k-1-n \leq i \leq k-2$ are the same as the terms $q_{j}$ for $k-1 \leq j \leq n-2$, which also appear in (4). Thus we have

$$
\begin{equation*}
q_{i}=s_{i+n}+s_{i+2 n-k}, \quad \text { where } \quad 2 k-1-n \leq i \leq k-2 . \tag{5}
\end{equation*}
$$

Moreover, we have $s_{i+n}=q_{i}+q_{i+n-k}$ for $0 \leq i \leq 2 k-2-n$. The terms $q_{i+n-k}$ for $0 \leq i \leq 2 k-2-n$ are the same as the terms $q_{j}$ for $n-k \leq j \leq k-2$, which appear in (5). Thus we have

$$
\begin{equation*}
q_{i}=s_{i+n}+s_{i+2 n-k}+s_{i+3 n-2 k}, \quad \text { where } 0 \leq i \leq 2 k-2-n . \tag{6}
\end{equation*}
$$

Using (4), (5) and (6), we get the following expression of $q$ :

$$
\begin{align*}
q & =\sum_{i=0}^{n-2} q_{i} x^{i} \\
& =\sum_{i=0}^{2 k-2-n}\left(s_{i+n}+s_{i+2 n-k}+s_{i+3 n-2 k}\right) x^{i}+\sum_{i=2 k-1-n}^{k-2}\left(s_{i+n}+s_{i+2 n-k}\right) x^{i}+\sum_{i=k-1}^{n-2} s_{i+n} x^{i} \\
& =\sum_{i=0}^{n-2} s_{i+n} x^{i}+\sum_{i=0}^{k-2} s_{i+2 n-k} x^{i}+\sum_{i=0}^{2 k-2-n} s_{i+3 n-2 k} x^{i} . \tag{7}
\end{align*}
$$

B. Compute the remainder $(c+q)=\langle a \cdot b\rangle_{f+1}$

Because $k<2 n / 3$, i.e., $3 k<2 n$, we have the Bezout identity

$$
x^{k} \cdot x^{2 n-3 k}+\left(x^{n-k}+1\right) \cdot\left(x^{n-k}+1\right)=1 .
$$

So we know that $x^{2 n-3 k}$ is the multiplicative inverse of $x^{k} \bmod \left(x^{n-k}+1\right)$ and $\left(x^{n-k}+1\right)$ is the multiplicative inverse of $\left(x^{n-k}+1\right) \bmod x^{k}$. Therefore, the remainder $(c+q)=\langle a \cdot b\rangle_{x^{n}+x^{k}}$ can be computed using the CRT as follows:

$$
\begin{equation*}
\langle a \cdot b\rangle_{x^{n}+x^{k}}=\left\langle\langle a \cdot b\rangle_{x^{k}} \cdot\left(x^{n-k}+1\right) \cdot\left(x^{n-k}+1\right)+\langle a \cdot b\rangle_{x^{n-k}+1} \cdot x^{k} \cdot x^{2 n-3 k}\right\rangle_{x^{n}+x^{k}} . \tag{8}
\end{equation*}
$$

Thus, we need to compute the terms $\langle a \cdot b\rangle_{x^{k}}$ and $\langle a \cdot b\rangle_{x^{n-k}+1}$ in (8) first. The expression of $\langle a \cdot b\rangle_{x^{k}}$ can be derived from the expression of $a \cdot b$ given in (1). It is clear that

$$
\begin{equation*}
\langle a \cdot b\rangle_{x^{k}}=\sum_{i=0}^{k-1} s_{i} x^{i} \tag{9}
\end{equation*}
$$

In order to compute the term $\langle a \cdot b\rangle_{x^{n-k}+1}=\left\langle\langle a\rangle_{x^{n-k}+1} \cdot\langle b\rangle_{x^{n-k}+1}\right\rangle_{x^{n-k}+1}$ in (8), we first compute $\langle a\rangle_{x^{n-k}+1}$. Since it is the input of the operation $\left\langle\langle a\rangle_{x^{n-k}+1} \cdot\langle b\rangle_{x^{n-k}+1}\right\rangle_{x^{n-k}+1}$, we define
it as $\sum_{i=0}^{n-k-1} g_{i} x^{i}$. Because $n / 2<k<2 n / 3$, i.e., $2 k-n-1<n-k-1$, we have

$$
\begin{align*}
& \sum_{i=0}^{n-k-1} a_{i} x^{i}:=\langle a\rangle_{x^{n-k}+1} \\
= & \left\langle\sum_{i=0}^{n-k-1} a_{i} x^{i}+\sum_{i=n-k}^{n-1} a_{i} x^{i}\right\rangle_{x^{n-k}+1} \\
= & \sum_{i=0}^{n-k-1} a_{i} x^{i}+\left\langle\sum_{j=0}^{k-1} a_{j+n-k} x^{j+n-k}\right\rangle_{x^{n-k}+1} \\
= & \sum_{i=0}^{n-k-1} a_{i} x^{i}+\left\langle\sum_{i=0}^{k-1} a_{i+n-k} x^{i}\right\rangle_{x^{n-k}+1} \\
= & \sum_{i=0}^{n-k-1} a_{i} x^{i}+\left\langle\sum_{i=0}^{n-k-1} a_{i+n-k} x^{i}+\sum_{i=n-k} a_{i+n-k} x^{i}\right\rangle_{x^{n-k}+1} \\
= & \sum_{i=0}^{n-k-1} a_{i} x^{i}+\sum_{i=0}^{n-k-1} a_{i+n-k} x^{i}+\left\langle\sum_{j=0}^{2 k-n-1} a_{j+2 n-2 k} x^{j+n-k}\right\rangle_{x^{n-k}+1} \\
= & \sum_{i=0}^{n-k-1} a_{i} x^{i}+\sum_{i=0}^{n-k-1} a_{i+n-k} x^{i}+\sum_{i=0}^{2 k-n-1} a_{i+2 n-2 k} x^{i} \\
= & \sum_{i=0}^{2 k-n-1}\left(a_{i}+a_{i+n-k}+a_{i+2 n-2 k}\right) x^{i}+\sum_{i=2 k-n}^{n-k-1}\left(a_{i}+a_{i+n-k}\right) x^{i} . \tag{10}
\end{align*}
$$

Similarly, we can obtain the expression of $\sum_{i=0}^{n-k-1} h_{i} x^{i}:=\langle b\rangle_{x^{n-k}+1}$.
Now the term $\langle a \cdot b\rangle_{x^{n-k}+1}$ in (8) can be calculated using the schoolbook polynomial multiplication algorithm in (1).

$$
\begin{align*}
& \langle a \cdot b\rangle_{x^{n-k}+1}=\left\langle\langle a\rangle_{x^{n-k}+1} \cdot\langle b\rangle_{x^{n-k}+1}\right\rangle_{x^{n-k}+1}=\left\langle\left(\sum_{i=0}^{n-k-1} g_{i} x^{i}\right)\left(\sum_{i=0}^{n-k-1} h_{i} x^{i}\right)\right\rangle_{x^{n-k+1}} \\
= & \left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}\right) x^{n-k-1}+\sum_{i=0}^{n-k-2}\left(\sum_{j=0}^{i} g_{j} h_{i-j}+\sum_{j=i+1}^{n-k-1} g_{j} h_{i+n-k-j}\right) x^{i} . \tag{11}
\end{align*}
$$

Based on the above equations (8), (9) and (11), we can obtain the following expression of the

$$
\begin{aligned}
& \text { remainder }(c+q)=\langle a \cdot b\rangle_{f+1} \text {. } \\
& (c+q)=\langle a \cdot b\rangle_{x^{n}+x^{k}} \\
& =\left\langle\langle a \cdot b\rangle_{x^{k}} \cdot\left(x^{n-k}+1\right) \cdot\left(x^{n-k}+1\right)+\langle a \cdot b\rangle_{x^{n-k}+1} \cdot x^{k} \cdot x^{2 n-3 k}\right\rangle_{x^{n}+x^{k}} \\
& =\left\langle\left(\sum_{i=0}^{k-1} s_{i} x^{i}\right) \cdot\left(x^{2 n-2 k}+1\right)+\right. \\
& \left.\left[\left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}\right) x^{n-k-1}+\sum_{i=0}^{n-k-2}\left(\sum_{j=0}^{i} g_{j} h_{i-j}+\sum_{j=i+1}^{n-k-1} g_{j} h_{i+n-k-j}\right) x^{i}\right] x^{2 n-2 k}\right\rangle_{x^{n}+x^{k}} \\
& =\sum_{i=0}^{k-1} s_{i} x^{i}+\left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}\right) x^{2 n-2 k-1} \\
& +\left\langle\sum_{i=0}^{k-1} s_{i} x^{i+2 n-2 k}+\sum_{i=0}^{n-k-2}\left(\sum_{j=0}^{i} g_{j} h_{i-j}+\sum_{j=i+1}^{n-k-1} g_{j} h_{i+n-k-j}\right) x^{i+2 n-2 k}\right\rangle_{x^{n}+x^{k}} \\
& =\sum_{i=0}^{k-1} s_{i} x^{i}+\left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}\right) x^{2 n-2 k-1}+\left\langle\sum_{i=0}^{2 k-n-1} s_{i} x^{i+2 n-2 k}+\sum_{i=2 k-n}^{k-1} s_{i} x^{i+2 n-2 k}\right\rangle_{x^{n}+x^{k}}+ \\
& \left\langle\sum_{i=0}^{2 k-n-1}\left(\sum_{j=0}^{i} g_{j} h_{i-j}+\sum_{j=i+1}^{n-k-1} g_{j} h_{i+n-k-j}\right) x^{i+2 n-2 k}+\right. \\
& \left.\sum_{i=2 k-n}^{n-k-2}\left(\sum_{j=0}^{i} g_{j} h_{i-j}+\sum_{j=i+1}^{n-k-1} g_{j} h_{i+n-k-j}\right) x^{i+2 n-2 k}\right\rangle_{x^{n}+x^{k}}
\end{aligned}
$$

$$
\begin{align*}
& =\sum_{i=0}^{k-1} s_{i} x^{i}+\left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}\right) x^{2 n-2 k-1}+ \\
& \sum_{i=0}^{2 k-n-1} s_{i} x^{i+2 n-2 k}+\sum_{i=0}^{2 k-n-1}\left(\sum_{j=0}^{i} g_{j} h_{i-j}+\sum_{j=i+1}^{n-k-1} g_{j} h_{i+n-k-j}\right) x^{i+2 n-2 k} \\
& +\left\langle\sum_{i=2 k-n}^{k-1} s_{i} x^{i+2 n-2 k}\right\rangle_{x^{n}+x^{k}}+\left\langle\sum_{i=2 k-n}^{n-k-2}\left(\sum_{j=0}^{i} g_{j} h_{i-j}+\sum_{j=i+1}^{n-k-1} g_{j} h_{i+n-k-j} x^{i+2 n-2 k}\right\rangle_{x^{n}+x^{k}}\right. \\
& =\sum_{i=0}^{k-1} s_{i} x^{i}+\left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}\right) x^{2 n-2 k-1}+ \\
& \sum_{i=2 n-2 k}^{n-1} s_{i-2 n+2 k} x^{i}+\sum_{i=2 n-2 k}^{n-1}\left(\sum_{j=0}^{i-2 n+2 k} g_{j} h_{i-2 n+2 k-j}+\sum_{j=i-2 n+2 k+1}^{n-k-1} g_{j} h_{i-n+k-j}\right) x^{i} \\
& +\sum_{i=2 k-n}^{k-1} s_{i} x^{i+n-k}+\sum_{i=2 k-n}^{n-k-2}\left(\sum_{j=0}^{i} g_{j} h_{i-j}+\sum_{j=i+1}^{n-k-1} g_{j} h_{i+n-k-j}\right) x^{i+(n-k)} \\
& =\sum_{i=0}^{k-1} s_{i} x^{i}+\left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}\right) x^{2 n-2 k-1}+ \\
& \sum_{i=2 n-2 k}^{n-1} s_{i-2 n+2 k} x^{i}+\sum_{i=2 n-2 k}^{n-1}\left(\sum_{j=0}^{i-2 n+2 k} g_{j} h_{i-2 n+2 k-j}+\sum_{j=i-2 n+2 k+1}^{n-k-1} g_{j} h_{i-n+k-j}\right) x^{i}+ \\
& \sum_{i=k}^{n-1} s_{i-(n-k)} x^{i}+\sum_{i=k}^{2 n-2 k-2}\left(\sum_{j=0}^{i-(n-k)} g_{j} h_{i-(n-k)-j}+\sum_{j=i-(n-k)+1}^{n-k-1} g_{j} h_{i-j}\right) x^{i} \\
& =\sum_{i=0}^{k-1} s_{i} x^{i}+\sum_{i=k}^{2 n-2 k-2}\left(\sum_{j=0}^{i-(n-k)} g_{j} h_{i-(n-k)-j}+\sum_{j=i-(n-k)+1}^{n-k-1} g_{j} h_{i-j}+s_{i-(n-k)} x^{i}+\right. \\
& \left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}+s_{n-k-1}\right) x^{2 n-2 k-1}+ \\
& \sum_{i=2 n-2 k}^{n-1}\left(s_{i-2 n+2 k}+s_{i-(n-k)}+\sum_{j=0}^{i-2 n+2 k} g_{j} h_{i-2 n+2 k-j}+\sum_{j=i-2 n+2 k+1}^{n-k-1} g_{j} h_{i-n+k-j}\right) x^{i} . \tag{12}
\end{align*}
$$

C. The expression of $c=a b$ in $G F\left(2^{n}\right)$

Based on the expressions of $q$, i.e., (7), and $c+q$, i.e., (12), we can obtain the expression of $c=q+(c+q)$ in $G F\left(2^{n}\right)$.

$$
\begin{align*}
& c=\sum_{i=0}^{2 k-2-n}\left(s_{i+n}+s_{i+2 n-k}+s_{i+3 n-2 k}\right) x^{i}+\sum_{i=2 k-1-n}^{k-2}\left(s_{i+n}+s_{i+2 n-k}\right) x^{i}+ \\
& \sum_{i=k-1}^{n-2} s_{i+n} x^{i}+\sum_{i=0}^{k-1} s_{i} x^{i}+ \\
& \sum_{i=k}^{2 n-2 k-2}\left(\sum_{j=0}^{i-(n-k)} g_{j} h_{i-(n-k)-j}+\sum_{j=i-(n-k)+1}^{n-k-1} g_{j} h_{i-j}+s_{i-(n-k)}\right) x^{i}+ \\
& \left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}+s_{n-k-1}\right) x^{2 n-2 k-1}+ \\
& \sum_{i=2 n-2 k}^{n-1}\left(s_{i-2 n+2 k}+s_{i-(n-k)}+\sum_{j=0}^{i-2 n+2 k} g_{j} h_{i-2 n+2 k-j}+\sum_{j=i-2 n+2 k+1}^{n-k-1} g_{j} h_{i-n+k-j}\right) x^{i} \\
& =\sum_{i=0}^{2 k-2-n}\left\{\left(\left(s_{i}\right)\right)+s_{i+n}+\left(s_{i+2 n-k}\right]+\left[s_{i+3 n-2 k}\right)\right\} x^{i}+ \\
& \left\{\left[\left[s_{2 k-1-n}\right]\right]+\left[\left[\left[s_{n+k-1}\right]\right]\right]+s_{2 k-1}\right\} x^{2 k-1-n}+ \\
& \sum_{i=2 k-n}^{k-2}\left\{\left[s_{i}+\left[s_{i+2 n-k}\right)\right]+\left(s_{i+n}\right]\right\} x^{i}+\left\{\left[\left[\left[s_{n+k-1}\right]\right]\right]+\left(s_{k-1}\right)\right\} x^{k-1} \\
& +\sum_{i=k}^{2 n-2 k-2}\left\{\sum_{j=0}^{i-(n-k)} g_{j} h_{i-(n-k)-j}+\sum_{j=i-(n-k)+1}^{n-k-1} g_{j} h_{i-j}+\left[s_{i-(n-k)}+s_{i+n}\right]\right\} x^{i} \\
& +\left\{\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}+\left[s_{n-k-1}+s_{3 n-2 k-1}\right]\right\} x^{2 n-2 k-1} \\
& +\sum_{i=2 n-2 k}^{n-2}\left\{\left[s_{i+n}+s_{i-(n-k)}\right]+\left(\left(s_{i-2 n+2 k}\right)\right)+\sum_{j=0}^{i-2 n+2 k} g_{j} h_{i-2 n+2 k-j}+\sum_{j=i-2 n+2 k+1}^{n-k-1} g_{j} h_{i-n+k-j}\right\} x^{i} \\
& +\left\{\left[\left[s_{2 k-n-1}\right]\right]+\left(s_{k-1}\right)+\sum_{j=0}^{2 k-n-1} g_{j} h_{2 k-n-1-j}+\sum_{j=2 k-n}^{n-k-1} g_{j} h_{k-1-j}\right\} x^{n-1} . \tag{13}
\end{align*}
$$

Here, we use different combinations of "(",")", "[" and "]" to represent the terms that can be reused.

## III. Two types of the CRT-based multipliers

In this section, we analysize the complexities of the Type-A and Type-B multiplier presented in [5]. Type-A multipliers achieve the minimal number of the XOR gates, but their time complexities are not optimal for some irreducible trinomials. Type-B multipliers overcome this disadvantage at
the cost of some more XOR gates. For the detailed description of these two types of multipliers, please refer to [5].

## A. Complexities of Type-A multipliers

We need to determine the complexities of all coefficients $c_{i}$ 's $(0 \leq i \leq n-1)$ in equation (13). This equation includes only terms $s_{i}, h_{i}$ and $g_{i}$.

The expressions of $s_{i}(0 \leq i \leq 2 n-2)$ are given in (1). For $0 \leq i \leq n-1$, the term $s_{i}=\sum_{j=0}^{i} a_{j} b_{i-j}$ is the summation of $i+1$ product terms $a_{j} b_{i-j}$. For $n \leq i \leq 2 n-2$, the term $s_{i}=\sum_{j=i+1-n}^{n-1} a_{j} b_{i-j}$ is the summation of $2 n-1-i$ product terms $a_{j} b_{i-j}$.

The expressions of $g_{i}(0 \leq i \leq n-k-1)$ are given in (10). The expression of $h_{i}$ is similar to that of $g_{i}$ and they have the same complexity. Clearly, the complexities to compute all $g_{i}$ and $h_{i}$ for $0 \leq i \leq n-k-1$ are $2((2 k-n) 2+(2 n-3 k))=2 k$ XOR gates and $2 T_{X}$ gate delay due to the parallelism.

TABLE I
The number of the product terms in the coefficient $c_{i}$ of $x^{i}$.

| $x^{i}$ | The number of the product terms |
| :---: | :---: |
| $0 \leq i \leq 2 k-2-n$ | $(\underline{i+1})+(2 n-1-(n+i))+(2 n-1-(i+2 n-k))+\overline{(2 n-1-(i+3 n-2 k))}=3 k-2-2 i$ |
| $i=2 k-1-n$ | $(2 k-1-n+1)+(2 n-1-(n+k-1))+(2 n-1-(n+2 k-1-n))=2 n-k$ |
| $2 k-n \leq i \leq n-k-1$ | $[(i+1)+(2 n-1-(i+2 n-k))]+(2 n-1-(n+i))=n+k-1-i$ |
| $n-k \leq i \leq k-2$ |  |
| $i=k-1$ | $\underline{L}+(2 n-1-(n+k-1))=n$ |
| $k \leq i \leq 2 n-2 k-2$ | $[(2 n-1-(i+n))+(i-n+k+1))]+(n-k)=n$ |
| $i=2 n-2 k-1$ | $[(n-k+1)+(2 n-1-(3 n-2 k-1))]+(n-k)=n$ |
| $2 n-2 k \leq i \leq n-2$ | $(n-k)+[(2 n-1-(n+i))+(i-n+k+1)]+(\underline{i-2 n+2 k+1})=2 k+1-n+i$ |
| $n-1$ | $(n-k)+\underline{k}+(\underline{2 k-1-n+1})=2 k$ |

For the simplicity of description, we also call $g_{i} h_{j}$ in (13) a product term. Therefore, the number of the AND gates used in the proposed multipliers is equal to the of the product terms excluding the reusable terms. Table I lists the number of the product terms in each coefficient of $x^{i}$. The numbers of the reusable product terms are overlined and underlined in the table.

So the number of the AND product terms can be saved are:

$$
\begin{align*}
\phi_{\mathrm{AND}}= & (n-k) k+k+\sum_{i=0}^{2 k-2-n}(i+1)+ \\
& \sum_{i=0}^{2 k-2-n}(2 k-n-1-i)+\sum_{i=0}^{2 k-2-n}(k-1-i)  \tag{14}\\
= & 3 k^{2}-2 n k-k+n / 2+n^{2} / 2
\end{align*}
$$

Therefore, the total number of the AND gates used in the Type-A multiplier is

$$
\begin{align*}
\Delta= & (2 n-3 k+1) n+\sum_{i=0}^{2 k-2-n}(3 k-2-2 i)+ \\
& \sum_{i=2 k-1-n}^{k-2}(n+k-1-i)+\sum_{i=2 n-2 k}^{n-2}(2 k+1+i-n)+2 k \\
& -3 k^{2}-2 n k-k+n / 2+n^{2} / 2 \\
= & \left(3 n^{2}+3 k^{2}-4 k n-n+k\right) / 2 \\
= & n^{2}+\frac{(n-k)(n-1-3 k)}{2} . \tag{15}
\end{align*}
$$

The number of the XOR gates that can be saved in the Type-A multiplier is:

$$
\begin{align*}
\phi_{\text {XOR_A }} & =(n-k-1)(k-1)+(k-1)+(k-2)+\sum_{i=0}^{2 k-2-n}(i)+ \\
& \sum_{i=0}^{2 k-2-n}(2 k-n-2-i)+\sum_{i=0}^{2 k-2-n}(k-2-i)  \tag{16}\\
= & 3 k^{2}-2 n k-6 k+5 n / 2+n^{2} / 2+1
\end{align*}
$$

Therefore, the total number of the XOR gates is the summation of $2 k$ (computing $g_{i}$ and $h_{i}$ ) and the number of " + " in equation (13) excluding the reusable terms:

$$
\begin{align*}
& 2 k+\left[\left(\Delta+\phi_{\text {AND }}\right)-n\right]-\phi_{\text {XOR_A }} \\
= & \Delta+7 k-3 n-1 . \tag{17}
\end{align*}
$$

We now derive the time complexity of the type-A multiplier using Table I, which is the maximum AND and XOR gate delays of the coefficient $c_{i}$ for $0 \leq i \leq n-1$.

For $0 \leq i \leq 2 k-n-2$, the maximum gate delay is from the coefficient

$$
c_{0}=s_{0}+s_{n}+s_{2 n-k}+s_{3 n-2 k}
$$

which includes $1+(n-1)+[k-1]+[2 k-1-n]=3 k-2$ product terms $a_{i} b_{j}$. In order to obtain the explicit gate delay formula of $c_{0}$, we assume that $2^{v-1}<k-1 \leq 2^{v}$ for some positive integer $v$. Because the terms $s_{2 n-k}$ and $s_{3 n-2 k}$, which are the summations of $[k-1]$ and [2k-1-n] product terms $a_{i} b_{j}$ respectively, will be reused, and $k-1$ is lager than $2 k-1-n$, we compute the $s_{2 n-k}$ first. These $k-1$ product terms can be XORed using a single binary XOR subtree of height $v$. Therefore, the total gate delay to compute the subtree of $s_{2 n-k}$ is $1 T_{A}+v T_{X}$. During the period to compute $s_{2 n-k}$, the $[2 k-1-n]$ product terms in $s_{3 n-2 k}$ can be XORed simultaneously.

The left $(n-1)+1+1=n+1$ product terms $a_{i} b_{j}$ can then be processed as follows. Let $n+1=y \cdot 2^{v}+z$ by the division algorithm, where $0 \leq z<2^{v}$. We split these $(n+1)$ product terms into $\left\lceil\frac{n+1}{2^{v}}\right\rceil$ groups, where the last group may have $z$ product terms if $z>0$ and the other groups have $2^{v}$ product terms each. During the period to compute $s_{2 n-k}$, i.e., $1 T_{A}+v T_{X}$, the product terms in these $\left\lceil\frac{n+1}{2^{v}}\right\rceil$ groups can be XORed in parallel using $\left\lceil\frac{n+1}{2^{v}}\right\rceil$ binary XOR subtrees of the same height $v$. Finally, these $\left\lceil\frac{n+1}{2^{v}}\right\rceil$ summations and the result of $s_{2 n-k}$ are XORed using a binary XOR tree at the cost of $\left\lceil\log _{2}\left(\left\lceil\frac{n+1}{2^{v}}\right\rceil+1\right)\right\rceil$ XOR gate delays. Therefore, the total XOR gate delay to compute the coefficient $c_{0}$ is

$$
\begin{equation*}
v+\left\lceil\log _{2}\left(\left\lceil\frac{n+1}{2^{v}}\right\rceil+1\right)\right\rceil=\left\lceil\log _{2}\left(n+1+2^{v}\right)\right\rceil \tag{18}
\end{equation*}
$$

where $2^{v-1}<k-1 \leq 2^{v}$.
For $i=2 k-n-1$, the coefficient

$$
c_{2 k-n-1}=s_{2 k-n-1}+s_{n+k-1}+s_{2 k-1}
$$

which includes $[\underline{2 k-n}]+[\underline{n-k}]+[2 n-2 k]=2 n-k$ product terms $a_{i} b_{j}$. In order to obtain the explicit gate delay formula of $c_{2 k-n-1}$, we assume that $2^{v-1}<n-k \leq 2^{v}$ for some positive integer $v$. Because the terms $s_{2 k-n-1}$ and $s_{n+k-1}$, which are the summation of $[2 k-n]$ and $[n-k]$ product terms $a_{i} b_{j}$ respectively, will be reused, and $n-k$ is lager than $2 k-n$, we compute the $s_{n+k-1}$ first. So these $n-k$ product terms can be XORed using a single binary XOR subtree of height $v$. Therefore, the total gate delay to compute the subtree of $s_{n+k-1}$ is $1 T_{A}+v T_{X}$. Besides, during the period to compute $s_{n+k-1}$, the $[2 k-n]$ product terms in $s_{2 k-n-1}$ can be XORed simultaneously. The left $2 n-2 k+1$ product terms $a_{i} b_{j}$ can then be processed as follows. Let $2 n-2 k+1=y \cdot 2^{v}+z$ by the division algorithm, where $0 \leq z<2^{v}$. We split these $2 n-2 k+1$ product terms into $\left\lceil\frac{2 n-2 k+1}{2^{v}}\right\rceil$ groups, where the last group may have $z$ product terms
if $z>0$ and the other groups have $2^{v}$ product terms each. During the period to compute $s_{n+k-1}$, i.e., $1 T_{A}+v T_{X}$, the product terms in these $\left\lceil\frac{2 n-2 k+1}{2^{v}}\right\rceil$ groups can be XORed in parallel using $\left\lceil\frac{2 n-2 k+1}{2^{v}}\right\rceil$ binary XOR subtrees of the same height $v$. Finally, these $\left\lceil\frac{2 n-2 k+1}{2^{v}}\right\rceil$ summations and the result of $s_{n+k-1}$ are XORed using a binary XOR tree at the cost of $\left\lceil\log _{2}\left(\left\lceil\frac{2 n-2 k+1}{2^{v}}\right\rceil+1\right)\right\rceil$ XOR gate delays. Therefore, the total XOR gate delay to compute the coefficient $c_{2 k-n-1}$ is

$$
\begin{equation*}
v+\left\lceil\log _{2}\left(\left\lceil\frac{2 n-2 k+1}{2^{v}}\right\rceil+1\right)\right\rceil=\left\lceil\log _{2}\left(2 n-2 k+1+2^{v}\right)\right\rceil \tag{19}
\end{equation*}
$$

where $2^{v-1}<n-k \leq 2^{v}$.
For $2 k-n \leq i \leq k-2$, the maximum gate delay is from the coefficient

$$
c_{2 k-n}=\left[s_{2 k-n}+s_{n+k}\right]+s_{2 k}
$$

which includes $[(2 k-n+1)+(n-k-1)]+[2 n-2 k-1]=[\underline{k}]+[2 n-2 k-1]=2 n-k-1$ product terms $a_{i} b_{j}$. In order to obtain the explicit gate delay formula of $c_{2 k-n}$, we assume that $2^{v-1}<2 n-2 k-1 \leq 2^{v}$ for some positive integer $v$.

Because the terms $\left[s_{2 k-n}+s_{n+k}\right]$ and $s_{2 k}$, which are the summation of $[\underline{k}]$ and $2 n-2 k-1$ product terms $a_{i} b_{j}$ respectively, will be reused, and $2 n-2 k-1$ is larger than $[\underline{k}]$, we compute the terms of $s_{2 k}$ first. So these $2 n-2 k-1$ product terms can be XORed using a single binary XOR subtree of height $v$. Therefore, the total gate delay to compute the subtree of $s_{2 k}$ is $1 T_{A}+v T_{X}$. Besides, during the period to compute $s_{2 k}$, the $[\underline{k}]$ product terms in $\left[s_{2 k-n}+s_{n+k}\right]$ can be XORed simultaneously. Therefore, the total XOR gate delay to compute the coefficient $c_{2 k-n}$ is

$$
\begin{equation*}
v+1=\left\lceil\log _{2}\left(2^{v+1}\right)\right\rceil \leq\left\lceil\log _{2}\left(4 n-4 k-2+2^{v}\right)\right\rceil \tag{20}
\end{equation*}
$$

by the following lemma 1 [5] and $2^{v-1}<2 n-2 k-1 \leq 2^{v}$.
Lemma 1: Let $v$ and $i$ be positive integers. If $i \geq 2^{v}$ then $v+\left\lceil\log _{2}\left\lceil\frac{i}{2^{v}}\right\rceil\right\rceil=\left\lceil\log _{2} i\right\rceil$.
For $c_{k-1}$, the coefficient

$$
c_{k-1}=s_{n+k-1}+s_{k-1}
$$

which includes $[n-k]+[\underline{k}]=n$ product terms $a_{i} b_{j}$. We can get the delay of $c_{k-1}$ using the same way we compute the $c_{i}$ of $2 k-n \leq i \leq k-2$. Therefore, the total XOR gate delay to compute the coefficient $c_{k-1}$ is

$$
\begin{equation*}
v+1=\left\lceil\log _{2}\left(2^{v+1}\right)\right\rceil \leq\left\lceil\log _{2}\left(2 k+2^{v}\right)\right\rceil \tag{21}
\end{equation*}
$$

by lemma 1 and $2^{v-1}<k \leq 2^{v}$.

For $k \leq i \leq 2 n-2 k-2$, the coefficient is

$$
c_{i}=\sum_{j=0}^{i-(n-k)} g_{j} h_{i-(n-k)-j}+\sum_{j=i-(n-k)+1}^{n-k-1} g_{j} h_{i-j}+\left[s_{i-(n-k)}+s_{i+n}\right] .
$$

Each coefficient $c_{i}$ includes a resuable term $\left[s_{i-(n-k)}+s_{i+n}\right]$ and $n-k$ product terms $g_{i} h_{j}$. The reusable term, which is also part of the terms in $c_{i}$ for $2 k-n \leq i \leq k-2$, includes $(k-n+1+i)+(n-1-i)=k$ product terms $a_{i} b_{j}$. Therefore, these coefficients $c_{i}$ 's have the same distribution pattern of the product terms $a_{i} b_{j}$ and $g_{i} h_{j}$, and their gate delays are equal. In order to compute $c_{i}$, the terms $g_{i}$ and $h_{i}$ should be generated first according to equation (10), and then they are ANDed in the schoolbook multiplication (11). The product terms $g_{i} h_{j}$ are just the intermediate result of this multiplication operation, and they can be generated at the cost of $\left(1 T_{A}+2 T_{X}\right)$ gate delays. Then these coefficients $c_{i}$ 's can be computed similar to the way we computed $c_{0}$. The only difference is that all product terms in $c_{0}$ are of the form $a_{i} b_{j}$, but the terms $g_{i}$ and $h_{i}$ here should be generated first using $2 T_{X}$ delay. Therefore, the size of the groups should be halved twice, and the total XOR gate delay to compute these coefficients is

$$
\begin{equation*}
v+\left\lceil\log _{2}\left(\left\lceil\frac{n-k}{2^{v-2}}\right\rceil+1\right)\right\rceil=\left\lceil\log _{2}\left(4 n-4 k+2^{v}\right)\right\rceil \tag{22}
\end{equation*}
$$

where $2^{v-1}<k \leq 2^{v}$.
The case for the gate delays of $c_{2 n-2 k-1}$ is the same as $c_{i}$ while $k \leq i \leq 2 n-2 k-2$.
We now count the gate delay of the coefficient $c_{i}$ for $2 n-2 k \leq i \leq n-2$, i.e.,the maximum gate delay is from the coefficient

$$
c_{n-2}=\left[s_{2 n-2}+s_{k-2}\right]+\left[s_{2 k-n-2}\right]+\sum_{j=0}^{2 k-n-2} g_{j} h_{2 k-n-2-j}+\sum_{j=2 k-n-1}^{n-k-1} g_{j} h_{n-2-j} .
$$

The coefficient $c_{n-2}$ includes a reusable term $\left[s_{2 n-2}+s_{k-2}\right]$, a reusable term $\left[s_{2 k-n-2}\right]$ and $n-k$ product terms $g_{i} h_{j}$. In order to compute $c_{i}$, the terms $g_{i}$ and $h_{i}$ should be generated first according to equation(10), and they can be generated at the cost of $\left(1 T_{A}+2 T_{X}\right)$ gate delays as we have discussed above. Because the terms $\left[s_{2 n-2}+s_{k-2}\right]$ and $\left[s_{2 k-n-2}\right]$, which are the summation of $[\underline{k}]$ and $[2 k-n-1]$ product terms $a_{i} b_{j}$ respectively, will be reused, and $[\underline{k}]$ is larger than $[2 k-n-1]$, we compute the terms $\left[s_{2 n-2}+s_{k-2}\right]$ first. Then coefficient $c_{n-2}$ can be computed similar to the way we computed $c_{i}$ for $k \leq i \leq 2 n-2 k-2$. The total XOR gate delay to compute $c_{n-2}$ is

$$
\begin{equation*}
v+\left\lceil\log _{2}\left(\left\lceil\frac{n-k+1}{2^{v-2}}\right\rceil+1\right)\right\rceil=\left\lceil\log _{2}\left(4 n-4 k+4+2^{v}\right)\right\rceil \tag{23}
\end{equation*}
$$

where $2^{v-1}<k \leq 2^{v}$.
The gate delay of the coefficient $c_{i}$ for $n-1$ is as same as the the coefficient $c_{n-2}$.
As the value of $v$ is different among (18),(19),(20),(21),(22),(23), comparing all the gate delay of $c_{i}$, the max gate delay is among (23) and (20). So the time complexity of the Type-A multiplier is $1 T_{A}+\left\lceil\log _{2}\left(\max \left(4 n-4 k+4+2^{v}, 4 n-4 k-2+2^{t}\right)\right)\right\rceil T_{X}$ where $2^{t-1}<2 n-2 k-1 \leq 2^{t}$ and $2^{v-1}<k \leq 2^{v}$.

## B. Complexities of Type-B multipliers

The method to compute the coefficient $c_{0}$ presented before (18) is not optimal for some values of $n$ and $k$. The Type-B multiplier is designed to overcome this disadvantage at the cost of some more XOR gates. In order to generalize this idea, we define $w(k)$ as the Hamming weight of the integer $k$. We also define $p(k)=\sum_{i=0}^{k} w(k)$. We first discuss the coefficient $c_{k-1}$ and $c_{n-1}$ which includes the reusable term $s_{k-1}$. They each include $k$ product terms $a_{i} b_{j}$, and we arrange them in the way discussed above. Thus we have $w(k)$ subtrees: the $j$-th nonzero bit in the binary expansion of $k$ corresponds to the subtree of height $j$. After constructing the binary XOR tree of $c_{k-1}$, we obtain the summation of leaf nodes in each subtree. These $w(k)$ subtree summations can then be XORed into the binary XOR tree of $c_{n-1}$ at the cost of $w(k)$ XOR gates. So the XOR gates can be saved of the reusable term $s_{k-1}$ are $k-w(k)$ while the TYPE-A is $k-1$.

Therefore, the number of the AND gates used in this type of multiplier is equal to that of the Type-A multiplier, but the number of the XOR gates can be saved is different. This number is

$$
\begin{align*}
\phi_{\text {XOR_B }}= & k-w(k)+(n-k-1)(k-w(k))+ \\
& (n-k-w(n-k))+(2 k-n-w(2 k-n))+ \\
& \sum_{i=1}^{2 k-1-n}(i-w(i))+\sum_{0}^{2 k-2-n}(k-1-i-w(k-1-i))+ \\
& \sum_{0}^{2 k-2-n}(2 k-1-n-i-w(2 k-1-n-i)) \\
= & 3 k^{2}-2 n k-k+n / 2+n^{2} / 2-w(k)(n-k)-w(2 k-n)-w(n-k) \\
& -(p(k-1)-p(n-k))-2 p(2 k-1-n) \tag{24}
\end{align*}
$$

Thus, the total number of the XOR gates of the Type-B multiplier is

$$
\begin{aligned}
& 2 k+\Delta+\left(3 k^{2}-2 n k-k+n / 2+n^{2} / 2\right)-n-\phi_{\text {XOR_B }} \\
= & \Delta+2 k-n+ \\
& w(k)(n-k)+w(2 k-n)+w(n-k)+2 p(2 k-1-n)+p(k-1)-p(n-k)
\end{aligned}
$$

The time complexity of the Type-B multiplier can be obtained similar to the way we processed $c_{i}$ in the Type-A multiplier before. For $0 \leq i \leq 2 k-2-n$, the maximum gate delay is from the coefficient $c_{0}$, which is $1 T_{A}+\left\lceil\log _{2}(3 k-2)\right\rceil T_{X}$. For $c_{n-1}$, the maximum XOR gate delay is $1 T_{A}+\left\lceil\log _{2}(3 n-k)\right\rceil T_{X}$. The gate delays of the other coefficients are not greater than those of $c_{n-1}$ and $c_{0}$. Because

$$
3 n-k>3 k-2 \text { when } n / 2<k<2 n / 3,
$$

the time complexity of the Type-B multiplier is equal to $1 T_{A}+\left\lceil\log _{2}(3 n-k)\right\rceil T_{X}$.

## IV. Type-A and Type-B multipliers for $k=2 n / 3$

In this case, similarly, we can obtain the following expression of computing $c=a b$ when $k=2 n / 3$. We can get the expression of computing $\langle a\rangle_{x^{n-k}+1}$.

$$
\begin{align*}
& \sum_{i=0}^{n-k-1} g_{i} x^{i}:=\langle a\rangle_{x^{n-k}+1} \\
= & \sum_{i=0}^{n-k-1} a_{i} x^{i}+\sum_{i=0}^{n-k-1} a_{i+n-k} x^{i}+\sum_{i=0}^{2 k-n-1} a_{i+2 n-2 k} x^{i} \\
= & \sum_{i=0}^{2 k-n-1}\left(a_{i}+a_{i+n-k}+a_{i+2 n-2 k}\right) x^{i} . \tag{25}
\end{align*}
$$

The expression of $c+q$ can be written as

$$
\begin{align*}
c+q= & \sum_{i=0}^{k-1} s_{i} x^{i}+\left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}\right) x^{n-1}+\sum_{i=2 n-2 k}^{n-1} s_{i-2 n+2 k} x^{i}+\sum_{i=k}^{n-1} s_{i-(n-k)} x^{i}+ \\
& \sum_{i=2 n-2 k}^{n-2}\left(\sum_{j=0}^{i-2 n+2 k} g_{j} h_{i-2 n+2 k-j}+\sum_{j=i-2 n+2 k+1}^{n-k-1} g_{j} h_{i-n+k-j}\right) x^{i} \\
= & \sum_{i=0}^{k-1} s_{i} x^{i}+ \\
& \sum_{i=k}^{n-2}\left(\sum_{j=0}^{i-2 n+2 k} g_{j} h_{i-2 n+2 k-j}+\sum_{j=i-2 n+2 k+1}^{n-k-1} g_{j} h_{i-n+k-j}+s_{i-2 n+2 k}+s_{i-(n-k)}\right) x^{i}+ \\
& \left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}+s_{2 k-n-1}+s_{k-1}\right) x^{n-1} . \tag{26}
\end{align*}
$$

So we can get the result $c$ :

$$
\begin{aligned}
c= & c+(c+q) \\
= & \sum_{i=0}^{k-1} s_{i} x^{i}+ \\
& \sum_{i=2 n-2 k}^{n-2}\left(\sum_{j=0}^{i-2 n+2 k} g_{j} h_{i-2 n+2 k-j}+\sum_{j=i-2 n+2 k+1}^{n-k-1} g_{j} h_{i-n+k-j}+s_{i-2 n+2 k}+s_{i-(n-k)}\right) x^{i}+ \\
& \left(\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}+s_{2 k-n-1}+s_{k-1}\right) x^{n-1}+ \\
& \sum_{i=0}^{2 k-2-n}\left(s_{i+n}+s_{i+2 n-k}+s_{i+3 n-2 k}\right) x^{i}+\sum_{i=2 k-1-n}^{k-2}\left(s_{i+n}+s_{i+2 n-k}\right) x^{i}+\sum_{i=k-1}^{n-2} s_{i+n} x^{i} \\
= & \sum_{i=0}^{2 k-2-n}\left\{\left(s_{i}\right)+s_{i+n}+\left(s_{i+2 n-k}\right]+\left[s_{i+3 n-2 k}\right)\right\} x^{i}+ \\
& \left\{\left[\left[s_{2 k-1-n}\right]\right]+\left(\left(\left(s_{n+k-1}\right)\right)\right)+s_{2 k-1}\right\} x^{2 k-1-n}+ \\
& \sum_{i=2 k-n}^{k-2}\left\{\left[s_{i}+\left[s_{i+2 n-k}\right)\right]+\left(s_{i+n}\right]\right\} x^{i}+\left\{\left(\left(s_{k-1}\right)\right)+\left(\left(\left(s_{n+k-1}\right)\right)\right)\right\} x^{k-1}+ \\
& \sum_{i=k}^{n-2}\left\{\sum_{j=0}^{i-2 n+2 k} g_{j} h_{i-2 n+2 k-j}+\sum_{j=i-2 n+2 k+1}^{n-k-1} g_{j} h_{i-n+k-j}+\left[s_{i+n}+s_{i-(n-k)}\right]+\left(s_{i-2 n+2 k}\right)\right\} x^{i}+ \\
& \left\{\left[\left[s_{2 k-n-1}\right]\right]+\left(\left(s_{k-1}\right)\right)+\sum_{j=0}^{n-k-1} g_{j} h_{n-k-1-j}\right\} x^{n-1} .
\end{aligned}
$$

## A. Type-A and Type-B multipliers

The two types of multipliers are similar to those presented in the previous section.
Table II lists the number of the product terms in each coefficient $c_{i}$ of $x^{i}$. The number of the AND gates in the Type-A and Type-B multipliers are all equal to the number of the product terms excluding the reusable terms. In this case, the num of AND gates can be saved are equal to the case of $2 / n<k<2 n / 3$.

$$
\begin{aligned}
\phi_{\mathrm{AND}} & =3 k^{2}-2 n k-k+n / 2+n^{2} / 2 \\
& =n^{2} / 2-n / 6 .
\end{aligned}
$$

Therefore, the total number of the AND gates is

$$
\begin{align*}
\Delta= & n+2 k+\sum_{i=0}^{2 k-2-n}(3 k-2-2 i)+ \\
& \sum_{i=2 k-1-n}^{k-2}(n+k-1-i)+\sum_{i=k}^{n-2}(2 k+1+i-n)-\phi_{\mathrm{AND}} \\
= & 4 n k+n / 2-k-3 k^{2}-n^{2} / 2 \\
= & \left(5 n^{2}-n\right) / 6 \tag{27}
\end{align*}
$$

which coincides with the value of $\Delta$ in (15).
The total number of the XOR gates in the Type-A multiplier is the summation of $2(2(2 k-n))=2 k$ (computing $g_{i}$ and $h_{i}$ ) and the number of " + " in equation (II) excluding the reusable terms. The XOR gates that can be saved in the Type-A multiplier are equal to the case of $2 / n<k<2 n / 3$.

$$
\begin{align*}
\phi_{\text {XOR_A }} & =3 k^{2}-2 n k-6 k+5 n / 2+n^{2} / 2+1  \tag{28}\\
& =n^{2} / 2-3 n / 2+1 .
\end{align*}
$$

So the total number of the XOR gates of the Type-A multiplier are:

$$
\begin{align*}
& 2 k+\left[\left(\Delta+\phi_{\mathrm{AND}}\right)-n\right]-\phi_{\mathrm{XOR} \_\mathrm{A}}  \tag{29}\\
= & \Delta+7 k-3 n-1 . \\
= & \left(5 n^{2}+9 n\right) / 6-1 .
\end{align*}
$$

Similarly, the XOR gates that can be saved in the Type-B multiplier are also the same as the case of $2 / n<k<2 n / 3$.

$$
\begin{align*}
\phi_{\text {XOR_B }}= & 3 k^{2}-2 n k-k+n / 2+n^{2} / 2-w(k)(n-k)-w(2 k-n)-w(n-k) \\
& -(p(k-1)-p(n-k))-2 p(2 k-1-n) \\
= & n^{2} / 2-n / 6-w(k)(n-k)-w(2 k-n)-w(n-k) \\
& -(p(k-1)-p(n-k))-2 p(2 k-1-n) \tag{30}
\end{align*}
$$

So the XOR gates in the Type-B multiplier are :

$$
\begin{align*}
& 2 k+\Delta+\phi_{\mathrm{AND}}-n-\phi_{\text {XOR_B }} \\
= & \left(5 n^{2}+n\right) / 6+ \\
& w(k)(n-k)+w(2 k-n)+w(n-k)+2 p(2 k-1-n)+ \\
& p(k-1)-p(n-k) . \tag{31}
\end{align*}
$$

The $w(k)$ and $p(x)$ functions are the same we defined above.

TABLE II
THE NUMBER OF THE PRODUCT TERMS IN THE COEFFICIENT $c_{i}$ OF $x^{i}$ WHILE $k=2 n / 3$.

| $x^{i}$ | The number of the product terms |
| :---: | :---: |
| $0 \leq i \leq 2 k-2-n$ | $(i+1)+(2 n-1-(n+i))+(2 n-1-(i+2 n-k))+\overline{(2 n-1-(i+3 n-2 k))}=3 k-2-2 i$ |
| $i=2 k-1-n$ | $(2 k-1-n+1)+(2 n-1-(n+k-1))+(2 n-1-(n+2 k-1-n))=2 n-k$ |
| $2 k-n \leq i \leq k-2$ | $[\underline{(i+1)+\overline{(2 n-1-(i+2 n-k)})}]+\underline{(2 n-1-(n+i))}=n+k-1-i$ |
| $i=k-1$ | $\underline{-}+(2 n-1-(n+k-1))=n$ |
| $k \leq i \leq n-2$ | $(n-k)+[(\underline{2 n-1-(n+i)})+(i-n+k+1)]+(\underline{i-2 n+2 k+1})=2 k+1-n+i$ |
| $n-1$ | $(n-k)+\underline{k}+(\underline{2 k-1-n+1})=2 k$ |

Then we discuss the gate delay of the case $k=2 n / 3$. For $0 \leq i \leq 2 k-n-2$, the maximum gate delay is from the coefficient

$$
c_{0}=s_{0}+s_{n}+s_{2 n-k}+s_{3 n-2 k}
$$

which includes $1+(n-1)+[\underline{k-1}]+[2 k-1-n]=3 k-2$ product terms $a_{i} b_{j}$. We can get the explicit gate delay in the Type-A multiplier using the way we discussed above. Therefore, the gate delay of $c_{0}$ in the Type-A multiplier is

$$
v+\left\lceil\log _{2}\left(\left\lceil\frac{n+1}{2^{v}}\right\rceil+1\right)\right\rceil=\left\lceil\log _{2}\left(3 k / 2+1+2^{v}\right)\right\rceil
$$

by lemma 1 and $2^{v-1}<k-1 \leq 2^{v}$.
As for the Type-B multiplier, the gate delay is $1 T_{A}+\left\lceil\log _{2}(3 k-2)\right\rceil T_{X}$.
For $i=2 k-n-1$, the coefficient

$$
c_{2 k-n-1}=s_{2 k-n-1}+s_{n+k-1}+s_{2 k-1}
$$

which includes $[\underline{2 k-n}]+[\underline{n-k}]+[2 n-2 k]=2 n-k=2 k$ product terms $a_{i} b_{j}$. For the Type-A multiplier, the gate delay is

$$
v+\left\lceil\log _{2}\left(\left\lceil\frac{2 n-2 k+1}{2^{v}}\right\rceil+1\right)\right\rceil=\left\lceil\log _{2}\left(k+1+2^{v}\right)\right\rceil
$$

by lemma 1 and $2^{v-1}<n-k \leq 2^{v}$. For the Type-B multiplier, the gate delay is $1 T_{A}+$ $\left\lceil\log _{2}(2 k)\right\rceil T_{X}$.

For $c_{k-1}$, the coefficient

$$
c_{k-1}=s_{n+k-1}+s_{k-1}
$$

which includes $[n-k]+[\underline{k}]=n=3 k / 2$ product terms $a_{i} b_{j}$. For the Type-A multiplier, the total XOR gate delay to compute the coefficient $c_{k-1}$ is

$$
v+\left\lceil\log _{2}(1+1)\right\rceil=\left\lceil\log _{2}\left(2^{v+1}\right)\right\rceil \leq\left\lceil\log _{2}\left(2 k+2^{v}\right)\right\rceil
$$

by lemma 1 and $2^{v-1}<k \leq 2^{v}$. For the Type-B multiplier, the total XOR gate delay is $1 T_{A}+\left\lceil\log _{2}(3 k / 2)\right\rceil T_{X}$.

For $k \leq i \leq n-2$, the maximum gate delay is from the coefficient

$$
c_{n-2}=\left[s_{2 n-2}+s_{k-2}\right]+\left[s_{2 k-n-2}\right]+\sum_{j=0}^{2 k-n-2} g_{j} h_{2 k-n-2-j}+\sum_{j=2 k-n-1}^{n-k-1} g_{j} h_{n-2-j}
$$

The coefficient $c_{n-2}$ includes a reusable term $\left[s_{2 n-2}+s_{k-2}\right]$, a reusable term $\left[s_{2 k-n-2}\right]$ and $n-k$ product terms $g_{i} h_{j}$. For the Type-A multiplier, the total XOR gate delay is

$$
v+\left\lceil\log _{2}\left(\left\lceil\frac{n-k+1}{2^{v-2}}\right\rceil+1\right)\right\rceil=\left\lceil\log _{2}\left(2 k+4+2^{v}\right)\right\rceil \leq\left\lceil\log _{2}(4 k+4)\right\rceil
$$

by lemma 1 and $2^{v-1}<k \leq 2^{v}$. For the Type-B multiplier, the total gate delay is $1 T_{A}+$ $\left\lceil 2+\log _{2}\left(\left\lceil\frac{3 k-n-2}{4}\right\rceil+(n-k)\right)\right\rceil T_{X}=1 T_{A}+\left\lceil\log _{2}(7 k / 2-2)\right\rceil T_{X}$.

For $c_{n-1}$, the gate delay of Type-A multiplier is as same as the the coefficient $c_{n-2}$. For the Type-B multiplier, the total XOR gate delay is $1 T_{A}+\left\lceil\log _{2}(7 k / 2)\right\rceil T_{X}$.

In summary, the max gate delays of Type-A and Type-B multipliers are $1 T_{A}+\left\lceil\log _{2}\left(2 k+4+2^{v}\right) T_{X}\right\rceil$ and $1 T_{A}+\left\lceil\log _{2}(7 k / 2)\right\rceil T_{X}$ respectively for the case $k=2 n / 3$.

A simple calculation show that the above expressions of space and time complexities for the case $k=2 n / 3$ are all coincides with those for the case $k \in(n / 2,2 n / 3)$ obtained in the previous section. Therefore, we combine them together and make a comparison in the next section.

## V. Comparisons

We list the complexities of the proposed multipliers and other trinomial-based parallel multipliers in Table III. Because their AND gate delays are all $1 T_{A}$, we ignore them and list only XOR gate delays in the last column.

TABLE III
COMPLEXITIES OF $f(u)=u^{n}+u^{k}+1$-BASED PARALLEL MULTIPLIERS

| Multipliers | \# AND Gate | \# XOR Gate | XOR Gate Delay |
| :---: | :---: | :---: | :--- |
| Quadratic, $2 k>n$ [7] [8] | $n^{2}$ | $n^{2}-1$ | $\left\lceil\log _{2}(n+k)\right\rceil$ |
| Quadratic, $2 k<n[7][8]$ | $n^{2}$ | $n^{2}-1$ | $\left\lceil\log _{2}(2 n-k-1)\right\rceil$ |
| Karatsuba hybrid $n$ even [6] | $\frac{3 n^{2}}{4}$ | $\frac{3 n^{2}}{4}+2.5 n+k-4$ | $\left\lceil\log _{2}(8 n-8)\right\rceil$ |
| Karatsuba hybrid $n$ odd [6] | $\frac{3 n^{2}+2 n-1}{4}$ | $\frac{3 n^{2}}{4}+4 n+k-5.75$ | $\left\lceil\log _{2}(8 n-8)\right\rceil$ |
| PB Type-A, $k \in(1, n / 2)[5]$ | $\Delta$ | $\Delta+3 k-n$ | $\left\lceil\log _{2}\left(\max \left(3 n-3 k-1,2 n-2 k+2^{v}\right)\right)\right\rceil$ |
| PB Type-B, $k \in(1, n / 2)[5]$ | $\Delta$ | $\Delta+2 k-n+k \cdot w(k)$ | $\left\lceil\log _{2}(3 n-3 k-1)\right\rceil$ |
| PB Type-A, $k \in(n / 2,2 n / 3]$ | $\Delta$ | $\Delta+7 k-3 n-1$ | $\left\lceil\log _{2}\left(\max \left(4 n-4 k+4+2^{v}, 4 n-4 k-2+2^{t}\right)\right)\right\rceil$ |
| PB Type-B, $k \in(n / 2,2 n / 3]$ | $\Delta$ | $\Delta+2 k-n+\sigma$ | $\left\lceil\log _{2}(3 n-k)\right\rceil$ |
| $\left.\begin{array}{l}\text { where } \Delta=n^{2}+(n-k)(n-1-3 k) / 2,2^{v-1}<k \leq 2^{v}, 2^{t-1}<2 n-2 k-1 \leq 2^{t}\end{array}\right]$ |  |  |  |
| $\sigma=w(k)(n-k)+w(n-k)+w(2 k-n)+2 p(2 k-1-n)+p(k-1)-p(n-k)$. |  |  |  |

The space complexity of the fastest quadratic parallel multipliers for irreducible trinomials are $n^{2}$ AND gates and $n^{2}-1$ XOR gates. It is easy to check that the following two inequalities are always valid for $n>4$ and $k \in(n / 2,2 n / 3]$ :

$$
\begin{cases}\text { \# AND gates: } & \Delta=n^{2}+(n-k)(n-1-3 k) / 2<n^{2} \\ \text { \# XOR gates: } & \Delta+7 k-3 n-1<n^{2}-1\end{cases}
$$

Therefore, the space complexity of the proposed multiplier is always less than that of the fastest quadratic parallel multipliers. As for the time complexity, thanks to the property of the ceiling function " $\lceil\cdot\rceil$ ", these multipliers may have the same XOR gate delay, depending on the values of $n$ and $k$.

For the purpose of comparison, we examine the 317 values of $n$ such that $n \in[5,999]$ and $u^{n}+u^{k}+1$ is irreducible over $G F(2)$ for some $k \in(n / 2,2 n / 3]$.

Compared to the current fastest parallel multipliers - quadratic multipliers, the space complexities are reduced, for all these 317 values of $n$, by $15.3 \%$ on average. Especially, for the 124 values of such $n$, the two kinds of multipliers have the same time complexity, but the space complexities are reduced by $15.5 \%$ on average. On the other hand, the CRT-based multipliers in [5] consider the case $k \in[2, n / 2]$, and reduce the space complexities by only $8.4 \%$ on average.

## VI. An example: $f=u^{21}+u^{14}+1$

From the expression of the quotient $q$ of $a \cdot b$ divided by $(f+1)=x^{21}+x^{14}$, i.e., (7), we have

$$
\begin{aligned}
q= & s_{40} x^{19}+s_{39} x^{18}+s_{38} x^{17}+s_{37} x^{16}+s_{36} x^{15}+s_{35} x^{14}+s_{34} x^{13} \\
& +\left(s_{33}+s_{40}\right) x^{12}+\left(s_{32}+s_{39}\right) x^{11}+\left(s_{31}+s_{38}\right) x^{10}+\left(s_{30}+s_{37}\right) x^{9} \\
& +\left(s_{29}+s_{36}\right) x^{8}+\left(s_{28}+s_{35}\right) x^{7}+\left(s_{27}+s_{34}\right) x^{6} \\
& +\left(s_{26}+s_{33}+s_{40}\right) x^{5}+\left(s_{25}+s_{32}+s_{39}\right) x^{4}+\left(s_{24}+s_{31}+s_{38}\right) x^{3}+\left(s_{23}+s_{30}+s_{37}\right) x^{2} \\
& +\left(s_{22}+s_{29}+s_{36}\right) x+\left(s_{21}+s_{28}+s_{35}\right) .
\end{aligned}
$$

In order to obtain $(c+q)=\langle a \cdot b\rangle_{x^{14}\left(x^{7}+1\right)}$ using the CRT, we compute $\langle a\rangle_{x^{7}+1}$ and $\langle b\rangle_{x^{7}+1}$ first.

$$
\begin{aligned}
\langle a\rangle_{x^{7}+1}= & \sum_{i=0}^{6} g_{i} x^{i} \\
= & \left(a_{0}+a_{7}+a_{14}\right)+\left(a_{1}+a_{8}+a_{15}\right) x+\left(a_{2}+a_{9}+a_{16}\right) x^{2}+\left(a_{3}+a_{10}+a_{17}\right) x^{3} \\
& +\left(a_{4}+a_{11}+a_{18}\right) x^{4}+\left(a_{5}+a_{12}+a_{19}\right) x^{5}+\left(a_{6}+a_{13}+a_{20}\right) x^{6} . \\
\langle b\rangle_{x^{7}+1}= & \sum_{i=0}^{6} h_{i} x^{i} \\
= & \left(b_{0}+b_{7}+b_{14}\right)+\left(b_{1}+b_{8}+b_{15}\right) x+\left(b_{2}+b_{9}+b_{16}\right) x^{2}+\left(b_{3}+b_{10}+b_{17}\right) x^{3} \\
& +\left(b_{4}+b_{11}+b_{18}\right) x^{4}+\left(b_{5}+b_{12}+b_{19}\right) x^{5}+\left(b_{6}+b_{13}+b_{20}\right) x^{6} .
\end{aligned}
$$

Next, we compute the two intermediate values in the CRT formula, i.e., (9) and (11), using the schoolbook polynomial multiplication algorithm:

$$
\langle a \cdot b\rangle_{x^{14}}=\sum_{i=0}^{13} s_{i} x^{i}
$$

and

$$
\begin{aligned}
\langle a \cdot b\rangle_{x^{n-k}+1}= & \left\langle\langle a\rangle_{x^{7}+1} \cdot\langle b\rangle_{x^{7}+1}\right\rangle_{x^{7}+1} \\
= & \left(g_{5} h_{1}+g_{0} h_{6}+g_{1} h_{5}+g_{2} h_{4}+g_{3} h_{3}+g_{4} h_{2}+g_{6} h_{0}\right) x^{6}+ \\
& \left(g_{2} h_{3}+g_{5} h_{0}+g_{0} h_{5}+g_{3} h_{2}+g_{4} h_{1}+g_{1} h_{4}+g_{6} h_{6}\right) x^{5}+ \\
& \left(g_{1} h_{3}+g_{2} h_{2}+g_{3} h_{1}+g_{0} h_{4}+g_{4} h_{0}+g_{5} h_{6}+g_{6} h_{5}\right) x^{4}+ \\
& \left(g_{1} h_{2}+g_{2} h_{1}+g_{0} h_{3}+g_{3} h_{0}+g_{6} h_{4}+g_{5} h_{5}+g_{4} h_{6}\right) x^{3}+ \\
& \left(g_{1} h_{1}+g_{0} h_{2}+g_{2} h_{0}+g_{6} h_{3}+g_{5} h_{4}+g_{3} h_{6}+g_{4} h_{5}\right) x^{2}+ \\
& \left(g_{1} h_{0}+g_{0} h_{1}+g_{6} h_{2}+g_{5} h_{3}+g_{2} h_{6}+g_{3} h_{5}+g_{4} h_{4}\right) x+ \\
& \left(g_{0} h_{0}+g_{4} h_{3}+g_{1} h_{6}+g_{2} h_{5}+g_{5} h_{2}+g_{6} h_{1}+g_{3} h_{4}\right) .
\end{aligned}
$$

Then, from the CRT expression of the remainder $(c+q)=\langle a \cdot b\rangle_{f+1}$, i.e., (8), we have

$$
\begin{aligned}
c+q= & \left\langle\langle a \cdot b\rangle_{x^{k}} \cdot\left(x^{n-k}+1\right) \cdot\left(x^{n-k}+1\right)+\langle a \cdot b\rangle_{x^{n-k}+1} \cdot x^{k} \cdot x^{2 n-3 k}\right\rangle_{x^{n}+x^{k}} \\
= & s_{0}+s_{1} x^{1}+s_{2} x^{2}+s_{3} x^{3}+s_{4} x^{4}+s_{5} x^{5}+s_{6} x^{6}+s_{7} x^{7}+s_{8} x^{8}+s_{9} x^{9}+ \\
& +s_{10} x^{10}+s_{11} x^{11}+s_{12} x^{12}+s_{13} x^{13}+ \\
& \left(s_{0}+s_{7}+g_{0} h_{0}+g_{4} h_{3}+g_{1} h_{6}+g_{2} h_{5}+g_{5} h_{2}+g_{6} h_{1}+g_{3} h_{4}\right) x^{14}+ \\
& \left(s_{1}+s_{8}+g_{1} h_{0}+g_{0} h_{1}+g_{6} h_{2}+g_{5} h_{3}+g_{2} h_{6}+g_{3} h_{5}+g_{4} h_{4}\right) x^{15}+ \\
& \left(s_{2}+s_{9}+g_{1} h_{1}+g_{0} h_{2}+g_{2} h_{0}+g_{6} h_{3}+g_{5} h_{4}+g_{3} h_{6}+g_{4} h_{5}\right) x^{16}+ \\
& \left(s_{3}+s_{10}+g_{1} h_{2}+g_{2} h_{1}+g_{0} h_{3}+g_{3} h_{0}+g_{6} h_{4}+g_{5} h_{5}+g_{4} h_{6}\right) x^{17}+ \\
& \left(s_{4}+s_{11}+g_{1} h_{3}+g_{2} h_{2}+g_{3} h_{1}+g_{0} h_{4}+g_{4} h_{0}+g_{5} h_{6}+g_{6} h_{5}\right) x^{18}+ \\
& \left(s_{5}+s_{12}+g_{2} h_{3}+g_{5} h_{0}+g_{0} h_{5}+g_{3} h_{2}+g_{4} h_{1}+g_{1} h_{4}+g_{6} h_{6}\right) x^{19}+ \\
& \left(s_{6}+s_{13}+g_{5} h_{1}+g_{0} h_{6}+g_{1} h_{5}+g_{2} h_{4}+g_{3} h_{3}+g_{4} h_{2}+g_{6} h_{0}\right) x^{20} .
\end{aligned}
$$

Finally, by (13), the expression of $c=a b=q+(c+q)$ is

$$
\begin{aligned}
c= & \left(\left(s_{0}\right)+s_{21}+\underline{s_{28}}+\overline{s_{35}}\right)+\left(\left(s_{1}\right)+s_{22}+\underline{s_{29}}+\overline{s_{36}}\right) x+ \\
& \left(\left(s_{2}\right)+s_{23}+\underline{s_{30}}+\overline{s_{37}}\right) x^{2}+\left(\left(s_{3}\right)+s_{24}+\underline{s_{31}}+\overline{s_{38}}\right) x^{3}+ \\
& \left(\left(s_{4}\right)+s_{25}+\underline{s_{32}}+\overline{s_{39}}\right) x^{4}+\left(\left(s_{5}\right)+s_{26}+\underline{s_{33}}+\overline{s_{40}}\right) x^{5}+ \\
& \left\{\left[\left[s_{6}\right]\right]+s_{27}+\left(\left(\left(s_{34}\right)\right)\right)\right\} x^{6}+ \\
& +\left(\left[s_{7}+\overline{s_{35}}\right]+\underline{s_{28}}\right) x^{7}+\left(\left[s_{8}+\overline{s_{36}}\right]+\underline{s_{29}}\right) x^{8}+\left(\left[s_{9}+\overline{s_{37}}\right]+\underline{s_{30}}\right) x^{9}+ \\
& \left(\left[s_{10}+\overline{s_{38}}\right]+\underline{s_{31}}\right) x^{10}+\left(\left[s_{11}+\overline{s_{39}}\right]+\underline{s_{32}}\right) x^{11}+\left(\left[s_{12}+\overline{s_{40}}\right]+\underline{s_{33}}\right) x^{12}+ \\
& \left\{\left(\left(s_{13}\right)\right)+\left(\left(\left(s_{34}\right)\right)\right)\right\} x^{13}+ \\
& \left(\left(s_{0}\right)+\left[s_{7}+s_{35}\right]+g_{0} h_{0}+g_{4} h_{3}+g_{1} h_{6}+g_{2} h_{5}+g_{5} h_{2}+g_{6} h_{1}+g_{3} h_{4}\right) x^{14}+ \\
& \left(\left(s_{1}\right)+\left[s_{8}+s_{36}\right]+g_{1} h_{0}+g_{0} h_{1}+g_{6} h_{2}+g_{5} h_{3}+g_{2} h_{6}+g_{3} h_{5}+g_{4} h_{4}\right) x^{15}+ \\
& \left(\left(s_{2}\right)+\left[s_{9}+s_{37}\right]+g_{1} h_{1}+g_{0} h_{2}+g_{2} h_{0}+g_{6} h_{3}+g_{5} h_{4}+g_{3} h_{6}+g_{4} h_{5}\right) x^{16}+ \\
& \left(\left(s_{3}\right)+\left[s_{10}+s_{38}\right]+g_{1} h_{2}+g_{2} h_{1}+g_{0} h_{3}+g_{3} h_{0}+g_{6} h_{4}+g_{5} h_{5}+g_{4} h_{6}\right) x^{17}+ \\
& \left(\left(s_{4}\right)+\left[s_{11}+s_{39}\right]+g_{1} h_{3}+g_{2} h_{2}+g_{3} h_{1}+g_{0} h_{4}+g_{4} h_{0}+g_{5} h_{6}+g_{6} h_{5}\right) x^{18}+ \\
& \left(\left(s_{5}\right)+\left[s_{12}+s_{40}\right]+g_{2} h_{3}+g_{5} h_{0}+g_{0} h_{5}+g_{3} h_{2}+g_{4} h_{1}+g_{1} h_{4}+g_{6} h_{6}\right) x^{19}+ \\
& \left(\left[\left[s_{6}\right]\right]+\left(\left(s_{13}\right)\right)+g_{5} h_{1}+g_{0} h_{6}+g_{1} h_{5}+g_{2} h_{4}+g_{3} h_{3}+g_{4} h_{2}+g_{6} h_{0}\right) x^{20} .
\end{aligned}
$$

The following table compares the space and time complexities of the proposed multipliers and the multipliers in [5]. We note that there are only four degree- 21 irreducible trinomials: $x^{21}+x^{2}+1, x^{21}+x^{7}+1$ and their reciprocal polynomials. The best choice for the multiplier in [5] is $x^{21}+x^{7}+1$.

TABLE IV
Complexities of CRT-based $G F\left(2^{21}\right)$ Parallel multipliers.

| Trinomial | Multiplier | \# AND Gate | \# XOR Gate | XOR Gate Delay |
| :---: | :---: | :---: | :---: | :---: |
| $x^{21}+x^{7}+1[5]$ | Type-A | 434 | 434 | 6 |
|  | Type-B | 434 | 448 | 6 |
| $x^{21}+x^{14}+1$ | Type-A | 364 | 398 | 6 |
|  | Type-B | 364 | 429 | 6 |

## VII. Conclusions

In this work, we consider the irreducible trinomial $u^{n}+u^{k}+1$ over $G F(2)$ for some $k \in$ ( $n / 2,2 n / 3$ ]. By selecting the largest possible value of $k \in(n / 2,2 n / 3]$, we further reduce the space complexity of the CRT-based hybrid parallel $G F\left(2^{n}\right)$ polynomial pasis multipliers. Compared to the current fastest parallel multipliers - quadratic multipliers, the AND and XOR gate complexities of the proposed multipliers are always less than those of the quadratic multipliers. Thanks to the property of the ceiling function " $\lceil\cdot\rceil$ ", they have the same time complexity for some irreducible trinomials.

For the purpose of comparison, we examine the 317 values of $n$ such that $n \in[5,999]$ and $u^{n}+u^{k}+1$ is irreducible over $G F(2)$ for some $k \in(n / 2,2 n / 3]$. The space complexities are reduced, for all these 317 values of $n$, by $15.3 \%$ on average. Especially, for the 124 values of such $n$, the two kinds of multipliers have the same time complexity, but the space complexities are reduced by $15.5 \%$ on average. On the other hand, the CRT-based multipliers in [5] consider the case $k \in[2, n / 2]$, and reduce the space complexities by only $8.4 \%$ on average.

## VIII. Acknowledgment

The authors thank the reviewers for their careful reading and useful comments. The work was supported by NSFC under grant No.s 61373141 and 91218302.
