

# Small Field Attack, and Revisiting RLWE-Based Authenticated Key Exchange from Eurocrypt’15\*

**Abstract.** Authenticated key exchange (AKE) plays a fundamental role in modern cryptography. Up to now, the HMQV protocol family is among the most efficient provably secure AKE protocols, which has been widely standardized and in use. Given recent advances in quantum computing, it is highly desirable to develop lattice-based analogue of HMQV protocols for the upcoming post-quantum era. Towards this goal, an important step was recently made by Zhang et al. at Eurocrypt’15 [ZZD<sup>+</sup>15,ZZDS14]. Similar to HMQV, this ring-LWE based analogue of HMQV proposed there consist of two variants: a two-pass protocol  $\Pi_2$ , as well as a one-pass protocol  $\Pi_1$  that implies a signcryption scheme (named as “deniable encryption” in [ZZD<sup>+</sup>15]). All these protocols are claimed to be provably secure under the ring-LWE (RLWE) assumption.

In this work, we propose a new type of attack, referred to as *small field attack* (SFA), against the one-pass protocol  $\Pi_1$  as well as its resultant deniable encryption scheme. With SFA, a malicious user can efficiently recover the static private key of the honest victim user in  $\Pi_1$  with overwhelming probability. Moreover, the SFA attack is *realistic and powerful in practice*, in the sense that it is *almost impossible* for the honest user to prevent, *or even detect*, the attack. Besides, some new property regarding the CRT basis of  $\mathcal{R}_q$  is also developed in this work, which is *essential* for our small field attack and may be of independent interest.

The security proof of the two-pass protocol  $\Pi_2$  is then revisited. We are stuck at Claim 16 in [ZZDS14], with a gap identified and discussed in the security proof. To us, we do not know how to fix the gap, which traces back to some critical differences between the security proof of HMQV and that of its RLWE-based analogue.

## 1 Introduction

Authenticated key exchange (AKE) plays a fundamental role in modern cryptography. Up to now, the HMQV protocol family [LMQ<sup>+</sup>03,Kra05] is generally considered to be the most efficient provably secure AKE protocol family, and has been standardized and widely in use. HMQV is built upon Diffie-Hellman (DH) [DH76], and consists of two variants: two-pass HMQV with provable security in the Canetti-Kraczye (CK) model [CK01], and one-pass HMQV with provable security in a tailored CK model for one-pass AKE [HK11]. Although two-pass HMQV is more frequently used in practice, one-pass HMQV itself is of great value and has many applications as well. For example, it was shown in [HK11] that one-pass HMQV implies secure higncryption (aka the *deniable encryption* in [ZZDS14,ZZD<sup>+</sup>15]), and has natural applications to key wrapping. However, HMQV will become insecure in the upcoming post-quantum era. Consequently, it would be much desirable to develop the HMQV-analogue based on lattice problems, since lattice-based cryptosystems are commonly believed to be resistant to quantum attacks.

As a ring variant of the learning with errors (LWE) problem [Reg09], the ring-LWE (RLWE) problem [LPR13a] was introduced to resolve some inefficiency issues of LWE-based cryptosystems. It is versatile, and has been well-studied ever since its introduction. Each ring-LWE instance is parameterized by a positive integer  $n$ , a positive rational prime  $q$ , a parameter  $\alpha > 0$ , and a monic irreducible polynomial  $f(x) \in \mathbb{Q}[x]$  of degree  $n$ . The hardness of ring-LWE problem is captured by a (possibly) quantum reduction from the approximate SVP problem in any ideal lattice of  $K$  to the decisional ring-LWE problem [LPR13a], where  $K \cong \mathbb{Q}[x]/\langle f \rangle$  denotes a number field of degree  $n$ . Ever since its introduction, significant cryptographic progress based on the RLWE problem has been made, *e.g.*, [LPR13a,LPR13b,Pei14,LS15,SS11,Gen09,GGH13a,GGH<sup>+</sup>13b,Lyu12,DDLL13]; For an excellent survey, the reader is referred to [Pei16].

In this work, the term “ring-LWE problem” refers to a *special* case of the *original* ring-LWE problem that is *widely used* in practice, *i.e.*,  $n \geq 16$  is a power-of-two,  $q$  is a positive rational prime such that  $q \equiv 1 \pmod{2n}$ , and  $f(x) = \Phi_{2n}(x) \in \mathbb{Z}[x]$  is the  $2n$ -th cyclotomic polynomial. For this (specific) ring-LWE problem, its search and decisional variants are proven *computationally equivalent* under mild constraints on the parameters [LPR13a,DD12].

**RLWE-based Diffie-Hellman and HMQV.** We briefly review the abstract basic structure of key exchange over RLWE [ZZDS14,ZZD<sup>+</sup>15,DXL12,Pei14,BCNS15,ADPS16]. Let Alice and Bob denote the two involved parties for simplicity. To Alice (party  $i$ ), the static private key is  $(s_i, e_i) \in \mathcal{R}_q \times \mathcal{R}_q$  (both are “small”), the static public

\* Communications with the corresponding authors of [ZZD<sup>+</sup>15,ZZDS14] are briefly summarized in Section A.

key is  $\mathbf{p}_i = \mathbf{a}\mathbf{s}_i + c \cdot \mathbf{e}_i$ , where  $\mathbf{a} \in \mathcal{R}_q$  denotes the public system parameter; the ephemeral private key is  $(\mathbf{r}_i, \mathbf{f}_i) \in \mathcal{R}_q \times \mathcal{R}_q$  (both are “small”), and the ephemeral public key is  $\mathbf{x}_i = \mathbf{a}\mathbf{r}_i + c \cdot \mathbf{f}_i$ . Similar notations  $(\mathbf{s}_j, \mathbf{e}_j), \mathbf{p}_j, (\mathbf{r}_j, \mathbf{f}_j), \mathbf{x}_j$  apply to Bob (party  $j$ ). The value  $c \in \mathbb{F}_q^\times$  is a public constant, which is set to be 1 in [Pei14] and to be 2 in [DXL12].

For the basic KE protocol without entity authentication (*i.e.*, Alice and Bob do not necessarily possess the static public/private keys), first Alice sends  $\mathbf{x}_i$  to Bob; Then Bob replies to Alice with  $(\mathbf{x}_j, \mathbf{w}_j = g(\mathbf{x}_i, \mathbf{r}_j, \mathbf{f}_j))$ , where  $g$  denotes a probabilistic polynomial-time (PPT) signal-generation function; Finally, Alice (resp., Bob) applies a key derivation function denoted  $K_i$  (resp.,  $K_j$ ), such that  $K_i(\mathbf{x}_j, \mathbf{r}_i, \mathbf{f}_i, \mathbf{w}_j) = K_j(\mathbf{x}_i, \mathbf{r}_j, \mathbf{f}_j, \mathbf{w}_j)$ . Briefly speaking, the underlying key derivation mechanism is based on the bilinear map  $(\mathbf{r}_1, \mathbf{r}_2) \rightarrow \mathbf{d} = \mathbf{r}_1 \cdot \mathbf{a} \cdot \mathbf{r}_2$  of  $\mathcal{R}_q \times \mathcal{R}_q$  into  $\mathcal{R}_q$ , where  $\mathbf{d} \in \mathcal{R}_q$  denotes the dominant value from which the session-key is derived. However, neither Alice nor Bob could *directly* compute the dominant value  $\mathbf{d}$  due to the small noises  $\mathbf{f}_i$  and  $\mathbf{f}_j$  involved, and the tricky part of the key derivation functions  $K_i$  and  $K_j$  is to reach the consensus on the shared key from two values that are “close” to the dominant value  $\mathbf{d}$ . This basic key exchange protocol is thus analogous to Diffie-Hellman, which in turn is based on bilinear map over cyclic group.<sup>1</sup> In two-pass RLWE-based HMQV analogue, we have  $\mathbf{w}_j = g(\mathbf{p}_i, \mathbf{x}_i, \mathbf{s}_j, \mathbf{e}_j, \mathbf{r}_j, \mathbf{f}_j)$ , and  $K_i(\mathbf{p}_j, \mathbf{x}_j, \mathbf{s}_i, \mathbf{e}_i, \mathbf{r}_i, \mathbf{f}_i, \mathbf{w}_j) = K_j(\mathbf{p}_i, \mathbf{x}_i, \mathbf{s}_j, \mathbf{e}_j, \mathbf{r}_j, \mathbf{f}_j, \mathbf{w}_j)$ . Conversely, in one-pass RLWE-based HMQV analogue where the values  $(\mathbf{x}_j, \mathbf{p}_j)$  sent by Bob in the second round is waived, Alice sends  $\mathbf{x}_i$  as well as the signal  $\mathbf{w}_i = g(\mathbf{p}_j, \mathbf{s}_i, \mathbf{e}_i, \mathbf{r}_i, \mathbf{f}_i)$ ; In this case,  $K_i$  and  $K_j$  are defined to be:  $K_i(\mathbf{p}_j, \mathbf{s}_i, \mathbf{e}_i, \mathbf{r}_i, \mathbf{f}_i, \mathbf{w}_i) = K_j(\mathbf{p}_i, \mathbf{x}_i, \mathbf{s}_j, \mathbf{e}_j, \mathbf{w}_i)$ .

An important step towards constructing the RLWE-based analogue of HMQV was recently made at Eurocrypt’15 [ZZD<sup>+</sup>15] and in its full version [ZZDS14], where the two-pass protocol  $\Pi_2$  and one-pass protocol  $\Pi_1$  were proposed. Both  $\Pi_2$  and  $\Pi_1$  are claimed to be provably secure under the ring-LWE assumption in the random oracle model, relative to a variant of the Bellare-Rogaway model [BR93] where adversary is not allowed to register public keys on behalf of dishonest users. In particular, for the one-pass variant  $\Pi_1$ , it is claimed to be provably secure “*in a weak model similar to [Kra05] which avoids some reasonable insufficiencies for one-pass protocol*” ([ZZD<sup>+</sup>15], page 744). However, the exact security model for  $\Pi_1$  is not made clear in [ZZD<sup>+</sup>15, ZZDS14], and the actual proof is omitted there. Similar to that one-pass HMQV implies signcryption, the work [ZZD<sup>+</sup>15, ZZDS14] also describes the signcryption scheme (*i.e.*, the “deniable encryption” in [ZZD<sup>+</sup>15, ZZDS14]) resultant from the one-pass variant  $\Pi_1$ , where the derived session-key is used for a CPA-secure symmetric encryption and a MAC scheme. The resultant signcryption is also claimed to be CCA-secure in [ZZD<sup>+</sup>15, ZZDS14], by following the analogue to one-pass HMQV.

The two-pass protocol  $\Pi_2$  is presented in Section 7. Below, we briefly review  $\Pi_1$  in Figure 4.1, in accordance with our abstract protocol structure above.

**The one-pass AKE scheme  $\Pi_1$**  The scheme  $\Pi_1$ , proposed in [ZZDS14, ZZD<sup>+</sup>15], is built upon the ring-LWE assumption. In  $\Pi_1$ ,  $\mathbf{a} \leftarrow \mathcal{R}_q$  is the global public parameter, and  $M > 0$  is a constant that is sufficiently large. As a two-party AKE protocol, users in  $\Pi_1$  are represented by party  $i$  and party  $j$ . For party  $i$ : the static private key is  $(\mathbf{s}_i, \mathbf{e}_i)$ , where  $\mathbf{s}_i, \mathbf{e}_i \leftarrow D_{\mathbb{Z}^n, \alpha}$ ; Its associated public key is  $\mathbf{p}_i \triangleq \mathbf{a}\mathbf{s}_i + 2\mathbf{e}_i \in \mathcal{R}_q$ ; And its identity issued by the Certificate Authority (CA) is  $\text{id}_i$ . Similar notations,  $\mathbf{s}_j, \mathbf{e}_j \leftarrow D_{\mathbb{Z}^n, \alpha}, \mathbf{p}_j \triangleq \mathbf{a}\mathbf{s}_j + 2\mathbf{e}_j \in \mathcal{R}_q$  and  $\text{id}_j$ , apply to party  $j$ . Let  $H_1 : \{0, 1\}^* \rightarrow D_{\mathbb{Z}^n, \gamma}$  be a hash function that outputs invertible elements in  $\mathcal{R}_q$ , and  $H_2 : \{0, 1\}^* \rightarrow \{0, 1\}^*$  be the key derivation function. Both  $H_1$  and  $H_2$  are regarded as random oracles in  $\Pi_1$ .

The following functions are essential for the definition of  $\Pi_1$ . First, When the prime  $q$  is clear from the context, define the function Parity :  $\mathbb{F}_q \rightarrow \{0, 1\}$ , where Parity( $u$ )  $\triangleq u \pmod{2} \in \{0, 1\}$ . Moreover, we define the function Mod :  $\mathbb{F}_q \times \{0, 1\} \rightarrow \{0, 1\}$ , where Mod( $u, w$ )  $\triangleq$  Parity( $(u + w \cdot q_0) \pmod{q}$ )  $\in \{0, 1\}$ . Finally, define the function Cha :  $\mathbb{F}_q \rightarrow \{0, 1\}$ , such that Cha( $u$ ) = 0 if and only if  $u \in \{-\frac{q-1}{4}, \dots, \frac{q-1}{4}\}$ ; Otherwise, Cha( $u$ ) = 1. All these functions could be easily generalized to the  $n$ -dimensional case in *the component-wise manner*; For instance, Cha( $\mathbf{v}$ )  $\triangleq [\text{Cha}(v_j)]_{j \in [n]} \in \{0, 1\}^n$  for every  $\mathbf{v} = [v_j]_{j \in [n]} \in \mathbb{F}_q^n$ , and it is understood that Cha( $\mathbf{u}$ )  $\triangleq$  Cha( $[u_j]_{j \in [n]}$ ) for  $\mathbf{u} = \sum_{j \in [n]} u_j \zeta^{j-1} \in \mathcal{R}_q$ .

## 1.1 Our Contributions

In this work, we propose a new type of efficient attack, referred to as *small field attack* (SFA), against the one-pass protocol  $\Pi_1$ , as well as its resultant “deniable encryption” proposed in [ZZDS14, ZZD<sup>+</sup>15]. With SFA, a malicious user  $i$  can efficiently recover the static private key of the honest user  $j$  in  $\Pi_1$  with overwhelming

<sup>1</sup> Unlike traditional DH protocol where a key pair may be caught for a short time to improve performance, for RLWE-based DH-analogue it is crucial that both parties use fresh ephemeral private keys in each session [Flu16, ADPS16].

**Fig. 1.** Description of  $\Pi_1$ . Note that in the full description in [ZZDS14,ZZD<sup>+</sup>15], party  $i$  applies the rejection sampling operation to generate a “good”  $(\mathbf{x}_i, \mathbf{w}_i)$  pair, which does not affect SFA and is omitted here for simplicity.

probability, after issuing a set of “random-looking” session queries with party  $j$ . The SFA attack is *realistic and powerful in practice*, in the sense that it is *almost impossible* for the honest party  $j$  to prevent, *or even detect*, the attack.<sup>2</sup> Besides, we also develop in this work a new property, *i.e.*, Proposition 5, regarding the CRT basis of  $\mathcal{R}_q$ , which is *essential* for our small field attack against  $\Pi_1$  and may be of independent interest.

We also notice that the SFA attack may not violate the security claim for  $\Pi_1$  made in [ZZD<sup>+</sup>15], as with SFA the malicious user needs to register its public key on its own (while in the omitted security model of [ZZD<sup>+</sup>15], the adversary may not be allowed to register public keys on behalf of dishonest users). Nevertheless, in our SFA, it is hard to distinguish the public key registered by a malicious user and the public key honestly generated. Moreover, as the malicious user does know the private key corresponding to the registered public key, traditional mechanisms for proof-of-knowledge (POK) or proof-of-possession (POP) of private key, *e.g.*, via requiring the user to sign a random message with the registered public key, does not prevent our SFA attack. From our point of view, forbidding adversary from registering public keys on behalf of dishonest users, on the one hand, seems to be unrealistic in practice; And, on the other hand, it may result in over weak security model as naturally insecure protocol like  $\Pi_1$  could be proved “secure” within.

Then, the security analysis of the two-pass AKE scheme  $\Pi_2$  in [ZZDS14,ZZD<sup>+</sup>15] is revisited. Loosely speaking, the security proof of  $\Pi_2$  considers five types of adversaries, Type-I through Type-V; Only Type-I is analyzed in [ZZD<sup>+</sup>15], and the complete analysis is presented in the full version [ZZDS14]. We are stuck at Claim 16 in [ZZDS14], which deals with Type-II adversary impersonating an honest user in the test-session without a matching session. A different conclusion on Claim 16 is reached, with a gap in the security proof identified and discussed. To us, we do not know how to fix the gap, which traces back to some *critical differences between the security proof of HMQV and that of its RLWE-based analogue*. Details are referred to Section 7.

Roughly speaking, given a pair of views  $(\text{view}_1, \text{view}_2)$  of a PPT adversary  $\mathcal{A}$ , consider the ability that  $\mathcal{A}$  could successfully output a value  $\sigma_t$ ,  $t \in \{1, 2\}$ , where  $\sigma_2$  is a random value independent of  $\text{view}_2$  but  $\sigma_1$  is essentially committed to  $\text{view}_1$  and is infeasible to be efficiently computed from  $\text{view}_1$ . The corresponding author of Claim 16 [ZZDS14] concludes that: if  $\text{view}_1$  and  $\text{view}_2$  are computationally indistinguishable and  $\mathcal{A}$  could not output  $\sigma_2$  from  $\text{view}_2$  with non-negligible probability, then  $\mathcal{A}$  should also not be able to output  $\sigma_1$  from  $\text{view}_1$  with non-negligible probability; In particular, whether  $\sigma_1$  is distinguishable from  $\sigma_2$  does not affect the conclusion. However,

<sup>2</sup> SFA works, in general, against the abstract structure of one-pass AKE discussed in Introduction, where both static private keys and ephemeral private keys get mixed in generating the key material from which the session key is derived. But it does not work against the analogues of RLWE-based Diffie-Hellman or SIGMA/TLS [DXL12,Pei14,BCNS15,ADPS16], where only ephemeral private keys are involved in session key generation.

from our view, to get the conclusion, we need to prove that the joint distribution of  $(\text{view}_1, \sigma_1)$  is computationally indistinguishable from that of  $(\text{view}_2, \sigma_2)$ ; At least we need to argue the indistinguishability between  $\sigma_1$  and  $\sigma_2$ , as the adversarial event is defined not only on the views  $(\text{view}_1, \text{view}_2)$  but also on the hidden values  $(\sigma_1, \sigma_2)$ . We do not know how to fix the gap. Details are referred to Section 7.

## 1.2 Outline of Small Field Attack

Here we present the outline of SFA, the main technical contribution of this work.

**The CRT basis of  $\mathcal{R}_q$  and its new property** Before introducing small field attack, we stress that our SFA makes full use of the notion of the CRT basis (of  $\mathcal{R}_q$ ) first proposed in [LPR13a]. Its basic properties can be summarized as follows. First, the CRT basis of  $\mathcal{R}_q$  is *unique*, and could be found efficiently [LPR13a]. Furthermore, the CRT basis  $\{c_1, \dots, c_n\}$  is an  $\mathbb{F}_q$ -basis of  $\mathcal{R}_q$ , when  $\mathcal{R}_q$  is seen as an  $\mathbb{F}_q$ -module of rank  $n$  in the natural way; For instance, every element  $\mathbf{u} \in \mathcal{R}_q$  could be *uniquely* written as  $\mathbf{u} = \sum_{i \in [n]} u_i c_i, u_i \in \mathbb{F}_q$ ; For simplicity, in this work let  $\eta_i(\mathbf{u}) \triangleq u_i \in \mathbb{F}_q$  denote the  $i$ -th CRT-coefficient of  $\mathbf{u} \in \mathcal{R}_q$ , and let  $\text{Dim}(\mathbf{u}) \triangleq \{i \in [n] \mid \eta_i(\mathbf{u}) \neq 0\}$ . Finally, the equality  $\mathbf{u}\mathbf{v} = \sum_{i \in [n]} \eta_i(\mathbf{u})\eta_i(\mathbf{v}) \cdot c_i$  holds in the ring  $\mathcal{R}_q$  for every  $\mathbf{u}, \mathbf{v} \in \mathcal{R}_q$ .

In addition to these basic ones, some interesting property regarding  $\{c_1, \dots, c_n\}$  is further developed in this work. To be precise, by assuming  $c_i = \sum_{j \in [n]} c_{i,j} \zeta^{j-1} \in \mathcal{R}_q, c_{i,j} \in \mathbb{F}_q$  for every  $i \in [n]$ , we shall prove in Proposition 5, Section 3.2, that for each  $i$ , the coefficients  $c_{i,1}, c_{i,2}, \dots, c_{i,n} \in \mathbb{F}_q$  form a geometric sequence (in  $\mathbb{F}_q$ ). This new property is essential for our SFA against  $\Pi_1$ , and may be of independent value.

**The small field attack (SFA)** The vulnerability of  $\Pi_1$  is demonstrated as follows. First, we abstract some of the valid functionalities of the honest party  $j$  in  $\Pi_1$  as an oracle  $\mathcal{M}_0$  with private key, where the private key of  $\mathcal{M}_0$  corresponds to the static private key of the honest party  $j$ . Each query made to  $\mathcal{M}_0$  consists of the caller's public key, the message  $\text{msg}$  for  $\mathcal{M}_0$  to create a new session, and the session key  $\text{sk}_i$  of the matching session. On each query,  $\mathcal{M}_0$  first creates a new session associated with  $\text{msg}$ , computes its session key  $\text{sk}_j$ , and finally returns 1 if  $\text{sk}_i = \text{sk}_j$ ; Otherwise, 0 is returned. Notice that such one-bit oracle is always available in practice, either by the session-key exposure oracle in the security model for one-pass HMQV [Kra05] or by the decryption oracle in the CCA-secure "deniable encryption" proposed in [ZZD<sup>+</sup>15, ZZDS14]. Moreover, for one-pass protocol  $\Pi_1$  is deployed in reality with mutual authentications by additionally exchanging MACs, the action differences of  $j$  upon receiving a valid MAC value or an invalid one can be used as such one-bit oracle. To demonstrate the vulnerability of  $\Pi_1$ , it is *sufficient* to construct an *efficient* attacker  $\mathcal{A}_0$  that can recover the private key of  $\mathcal{M}_0$ .

The precise construction of  $\mathcal{A}_0$  involves too many details. Fortunately, the following simplified analysis implies how  $\mathcal{A}_0$  against  $\mathcal{M}_0$  works. For the moment, we assume that the public key of  $\mathcal{A}_0$  is  $\mathbf{0} \in \mathcal{R}_q$  (this assumption could be dropped finally). In such simplified setting, we can define an oracle  $\mathcal{M}_1$  with secret  $\mathbf{s} \leftarrow D_{\mathbb{Z}^n, \alpha}$  which could be seen as a *simplified* variant of  $\mathcal{M}_0$ . Here,  $\mathbf{s}$  corresponds to the static private key of party  $j$  in  $\Pi_1$ , and could be seen as an element of  $\mathcal{R}_q$  in the natural way, provided  $q$  is sufficiently large. On input  $(\mathbf{x}, \mathbf{w}, \mathbf{z} = [z_j]_{j \in [n]}) \in \mathcal{R}_q \times \{0, 1\}^n \times \{0, 1\}^n$ , the oracle  $\mathcal{M}_1$  first generates a small error  $\varepsilon \leftarrow \mathbb{Z}_{1+2\theta}^n = \{-\theta, \dots, \theta\}^n$ , and then computes  $\sigma \triangleq \text{Parity}(\mathbf{x}\mathbf{s} + q_0\mathbf{w} + 2\varepsilon) = [\sigma_j]_{j \in [n]}$ , and finally returns 1 if and only if  $[\sigma_j]_{j \in [n]} = [z_j]_{j \in [n]}$ . In this work,  $\text{Parity}(x)$  represents the parity of  $x \in \mathbb{F}_q = \{-\frac{q-1}{2}, \dots, \frac{q-1}{2}\}$ ; Moreover, for  $\mathbf{u} = \sum_{j=1}^n u_j \zeta^{j-1} \in \mathcal{R}_q, u_j \in \mathbb{F}_q$ , it is understood  $\text{Parity}(\mathbf{u}) = [\text{Parity}(u_j)]_{j \in [n]} \in \{0, 1\}^n$ .

A simple efficient attacker  $\mathcal{A}_1$  against  $\mathcal{M}_1$  is first constructed in Section 4.3. Observe that if the  $\mathbf{x}$ -entry of every query is of the form  $k \cdot \mathbf{c}_i, k \in \mathbb{F}_q, i \in [n]$ , then the product  $\mathbf{x}\mathbf{s} = k\eta_i(\mathbf{s}) \cdot \mathbf{c}_i$  always belongs to a "small" set  $\langle \mathbf{c}_i \rangle = \{k' \cdot \mathbf{c}_i \mid k' \in \mathbb{F}_q\}$ , which is a *subfield* of the ring  $\mathcal{R}_q$  and is of size  $q = \text{poly}(\lambda) \ll q^n = |\mathcal{R}_q|$ , making it *possible* for us to recover  $\eta_i(\mathbf{s}) \in \mathbb{F}_q$  efficiently. This explains how our small field attack bears its name. Such observation implies the *general structure* of the desired attacker  $\mathcal{A}_1$ : the main body of  $\mathcal{A}_1$  is an  $n$ -round loop, and the  $i$ -th round is devoted to the recovery of  $s_i \triangleq \eta_i(\mathbf{s}) \in \mathbb{F}_q, i \in [n]$ ; In the  $i$ -th round, given  $s_1, \dots, s_{i-1} \in \mathbb{F}_q$  and oracle access to  $\mathcal{M}_1$ , it first picks  $\tilde{s}_i \leftarrow \mathbb{F}_q$  randomly, guesses  $s_i = \tilde{s}_i \in \mathbb{F}_q$ , and then verifies the correctness of this guess via a set  $\mathcal{Q}_i(\tilde{s}_i)$  of queries to  $\mathcal{M}_1$ ; The set  $\mathcal{Q}_i(\tilde{s}_i)$  is carefully chosen such that the  $\mathbf{x}$ -entry is always of the form  $k\mathbf{c}_i, k \in \mathbb{F}_q^\times$ , and the distribution of those query replies under the condition  $\tilde{s}_i = s_i$  is *computationally distinguishable* from that under the condition  $\tilde{s}_i \neq s_i$ ; In this manner, when  $\tilde{s}_i$  runs over the set  $\mathbb{F}_q$ , the exact value of  $s_i \in \mathbb{F}_q$  would be recovered successfully. In the end, the whole secret  $\mathbf{s} = \sum_{i \in [n]} s_i \cdot \mathbf{c}_i$  is recovered.

Of every query made by  $\mathcal{A}_1$ , its  $\mathbf{w}$ - and  $\mathbf{z}$ -entries are "random" enough, but its  $\mathbf{x}$ -entry is easy to recognize, since  $\mathbf{x} \in \{k\mathbf{c}_i \mid k \in \mathbb{F}_q^\times, i \in [n]\}$  always holds; Equivalently,  $|\text{Dim}(\mathbf{x})| = 1$ . As a result, it is easy for  $\mathcal{M}_1$  to prevent  $\mathcal{A}_1$  by requiring that  $|\text{Dim}(\mathbf{x})| \geq 2$  for each incoming query. Such restriction is *reasonable* in the sense that the set  $\{k\mathbf{c}_i \mid k \in \mathbb{F}_q^\times, i \in [n]\}$  is of "small" size compared with  $\mathcal{R}_q$ . Now the *first motivating question* arises:

how to improve  $\mathcal{A}_1$  so that we can still recover the secret of  $\mathcal{M}_1$ , even if the foregoing requirement on the  $\mathbf{x}$ -entry is imposed?

Actually, it is not hard to construct an improved variant of  $\mathcal{A}_1$ , *i.e.*,  $\mathcal{A}'_1$ , to resolve this problem, as we shall see in Section 5.1. First, given that in the  $i$ -th round, the CRT-coefficients  $s_1, \dots, s_{i-1}$  has already been recovered successfully, we can make full use of these known CRT-coefficients to re-design the  $\mathbf{x}$ -entry. Moreover, since  $\mathbf{s} \leftarrow D_{\mathbb{Z}^n, \alpha}$  is “small”, it can be proven that the product  $\mathbf{s}e \in \mathcal{R}_q$  is “small” as well for  $e \leftarrow [-\alpha'\sqrt{n}, \dots, \alpha'\sqrt{n}]^n$ . These two observations are essential for us to design the desired  $\mathcal{A}'_1$ : its *general structure* is almost the same as that of  $\mathcal{A}_1$ , except that in its  $i$ -th round, the  $\mathbf{x}$ -entry every query in  $\mathcal{Q}_i(\tilde{s}_i)$  is always of the form  $\mathbf{x} = k \cdot \mathbf{c}_i + \mathbf{h} + 2e$ , where  $k \in \mathbb{F}_q^\times$ ,  $\mathbf{h} \leftarrow \{\mathbf{u} \in \mathcal{R}_q \mid \text{Dim}(\mathbf{u}) = [i-1]\}$ , and  $e \leftarrow [-\alpha'\sqrt{n}, \dots, \alpha'\sqrt{n}]^n$ . By re-designing the  $w$ - and  $z$ -entries appropriately, the efficient attacker  $\mathcal{A}'_1$  can be proven to recover every CRT-coefficient  $s_i \in \mathbb{F}_q$  with overwhelming probability.

Clearly  $\text{Dim}(k \cdot \mathbf{c}_i + \mathbf{h}) = [i] = \{1, 2, \dots, i\}$ , and hence the more CRT-coefficients of  $\mathbf{s}$  we get, the more difficult for  $\mathcal{M}_1$  to identify those queries made by  $\mathcal{A}'_1$ . However, there is still another problem with  $\mathcal{A}'_1$ : in its *first* round, for every query made by  $\mathcal{A}'_1$ ,  $\mathbf{h} = \mathbf{0} \in \mathcal{R}_q$  and hence the  $\mathbf{x}$ -entry is of the form  $\mathbf{x} = k\mathbf{c}_i + 2e$ . To protect its secret,  $\mathcal{M}_1$  may reject those queries for which the  $\mathbf{x}$ -entries are of the form  $\mathbf{x} = k\mathbf{c}_i + 2e$  such that  $k \in \mathbb{F}_q, i \in [n]$  and  $\|e\|_\infty$  is “small”. Such requirement seems reasonable as well. Now the *second motivating question* arises: how to improve  $\mathcal{A}'_1$  so that we can still recover the secret of  $\mathcal{M}_1$ , even if the foregoing requirement on the  $\mathbf{x}$ -entry is imposed?

It turns out this question could be resolved *indirectly*. As in Section 5.2, we can define an *efficient* solver  $\mathcal{V}$  to the following problem: given a nonempty index set  $I \subseteq [n]$ , an  $|I|$ -dimensional vector  $[\tilde{s}_i]_{i \in I} \in \mathbb{F}_q^{|I|}$ , and oracle access to  $\mathcal{M}_1$ , decide whether  $[\tilde{s}_i]_{i \in I} = [s_i]_{i \in I}$  or not. Moreover, as we shall see, to solve the instance  $(I, [\tilde{s}_i]_{i \in I})$ , the  $\mathbf{x}$ -entry of every query made by  $\mathcal{V}$  to  $\mathcal{M}_1$  is of the form  $\mathbf{x}_0 + 2e$ , where  $\text{Dim}(\mathbf{x}_0) = I$  and  $e \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n = \{-\alpha'\sqrt{n}, \dots, \alpha'\sqrt{n}\}^n$ . With the aid of  $\mathcal{V}$ , we can construct an *efficient hybrid* attacker against  $\mathcal{M}_1$  as follow:

**Phase 1** First, choose a *constant*  $\delta$  of moderately large, and an index set  $I \subseteq [n]$  of size  $\delta$  *randomly*. Then, feed  $\mathcal{V}$  with  $q^\delta$  instances, each of the form  $(I, [\tilde{s}_i]_{i \in I})$ ,  $\tilde{s}_i \in \mathbb{F}_q$ . In this manner, the CRT-coefficients  $s_i, i \in I$ , would be recovered successfully when  $[\tilde{s}_i]_{i \in I}$  runs over the set  $\mathbb{F}_q^\delta$ .

In particular, the  $\mathbf{x}$ -entry of every query made in this phase is always of the form  $\mathbf{x}_0 + 2e$ , where  $\text{Dim}(\mathbf{x}_0) = I$ , and  $e \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ . Given the randomness of  $I$ , it is *almost impossible in practice* for  $\mathcal{M}_1$  to identify those queries made by  $\mathcal{V}$ .

**Phase 2** This phase consists of  $n - \delta$  rounds, each devoted to recovering one of the remaining  $n - \delta$  CRT-coefficients of  $\mathbf{s}$ , as is done in  $\mathcal{A}'_1$ .

In particular, the  $\mathbf{x}$ -entry of every query made in this phase is always of the form  $\mathbf{x}_0 + 2e$  where  $\text{Dim}(\mathbf{x}_0) \supseteq I$  and  $e \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ , making it *more difficult* for  $\mathcal{M}_1$  to identify them.

The notation  $(\mathcal{V}/\mathcal{A}'_1)_\delta$  is applied to indicate this efficient *hybrid* attacker against  $\mathcal{M}_1$ . Clearly, it is *almost impossible in practice* for  $\mathcal{M}_1$  to identify those malicious queries made by  $(\mathcal{V}/\mathcal{A}'_1)_\delta$ . This finishes our discussion about our small field attack against  $\mathcal{M}_1$ , a simplified variant of  $\mathcal{M}_0$ .

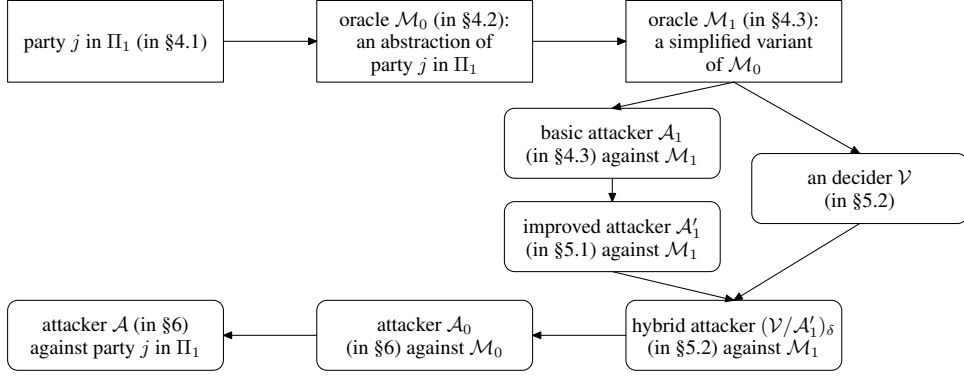

The desired efficient attacker  $\mathcal{A}_0$  against  $\mathcal{M}_0$  is similar to  $(\mathcal{V}/\mathcal{A}'_1)_\delta$  against  $\mathcal{M}_1$ . Likewise, these queries made by  $\mathcal{A}_0$  is so “random-looking” that it is *almost impossible in practice* for  $\mathcal{M}_0$  to identify them. Last but not the least, motivated by the construction of  $\mathcal{V}$ , we can also set the public key of  $\mathcal{A}_0$  in a clever way such that it is *almost impossible in practice* to distinguish the public key of  $\mathcal{A}_0$  from that of an honest user.

Our analysis can be briefly summarized as follows, as is depicted in Figure 2.

## 2 Preliminaries

Let  $\lambda$  denote the security parameters throughout this work. Let  $\mathbb{B} \triangleq \{0, 1\}$ . For an odd integer  $p > 0$ , let  $\mathbb{Z}_p \triangleq \{-\frac{p-1}{2}, \dots, \frac{p-1}{2}\}$ ; For instance,  $\mathbb{Z}_3 = \{-1, 0, 1\}$ . For every positive integer  $k$ , let  $[k]$  denote the finite set  $\{1, 2, \dots, k\} \subseteq \mathbb{Z}$ . The logical symbols, such as “ $\exists$ ” and “ $\forall$ ”, are applied in the conventional manner.

Throughout this work, let  $n \geq 16$  be a power-of-two, and  $q = \text{poly}(\lambda)$  be a positive rational prime that is polynomial in  $\lambda$ ; Moreover,  $q \equiv 1 \pmod{2n}$  is necessarily required. When  $q$  is clear from the context, define  $q_0 \triangleq \frac{q-1}{2}$ . Let  $\mathbb{F}_q \triangleq \mathbb{Z}/q\mathbb{Z}$  be the finite field of prime order  $q$ ; In this work, every element in  $\mathbb{F}_q$  is represented by a unique element in  $\{-q_0, \dots, q_0\}$ . Define  $\mathbb{F}_q^\times \triangleq \mathbb{F}_q \setminus \{0\}$ , and  $\text{zone}_0 \triangleq \{-q_0/2, \dots, +q_0/2\} \subseteq \mathbb{F}_q$ . And, when comparison is carried out between  $a, b \in \mathbb{F}_q$ , both  $a, b$  are regarded as *real numbers*.

**Fig. 2.** The presentation organization of the small field attack. Here, the arrows indicate the order in which our analysis is carried out.

Unless otherwise stated, vectors are represented in *column* form in this work, and the  $n$ -dimensional vector  $(u_1, \dots, u_n)^t$  is usually abbreviated as  $[u_j]_{j \in [n]}$ . Let  $\mathbf{0} \triangleq (0, \dots, 0)^t \in \mathbb{F}_q^n$ . When either  $\mathbf{u} \in \mathbb{F}_q^n$  or  $\mathbf{u} \in \mathbb{Z}^n$ , let  $\|\mathbf{u}\|_2$  and  $\|\mathbf{u}\|_\infty$  denote the  $\ell_2$ - and  $\ell_\infty$ -norms of  $\mathbf{u}$ ; For instance,  $\|[u_j]_{j \in [n]}\|_2 = \sqrt{u_1^2 + \dots + u_n^2} \in \mathbb{R}^{\geq 0}$ . When  $n$  and  $q$  are clear in the context, define the projection  $\mu_j : \mathbb{F}_q^n \rightarrow \mathbb{F}_q$  for every  $j \in [n]$  such that  $\mu_j([u_j]_{j \in [n]}) \triangleq u_j$ .

For an event  $E$ , the notation “ $\Pr[E] = \text{negl}(\lambda)$ ” indicates the probability that  $E$  occurs is negligible in  $\lambda$ . Conversely, if  $\Pr[E] = 1 - \text{negl}(\lambda)$ , we say that  $E$  occurs *with overwhelming probability*; For simplicity, the phrase “with overwhelming probability” is usually abbreviated as “*w.o.p.*” in this work. For a *deterministic* algorithm  $A$  that returns  $y$  on input  $x_1, x_2, \dots, x_k$ , this process is usually written as  $y := A(x_1, x_2, \dots, x_k)$ . Conversely, for a *randomized* algorithm  $B$ , which returns  $y$  on input  $x_1, x_2, \dots, x_k$  as well as the random nonce  $r$ , this process is usually abbreviated as  $y := B(x_1, x_2, \dots, x_k; r)$ , or simply  $y \leftarrow B(x_1, x_2, \dots, x_k)$ . The notation  $\Pr[R_1; \dots; R_k : E]$  denotes the probability of the event  $E$  after the *ordered* execution of random processes  $R_1, \dots, R_k$ . For a *finite* set  $S$ , let  $x \leftarrow S$  denote a sample drawn from the *uniform* distribution over the (finite) set  $S$ .

### 3 The CRT Basis in the Ring-LWE Setting

This section reviews the ring-LWE problem and its associated notions/results. The definition of the ring-LWE problem, as well as its hardness results, is reviewed in Section 3.1. In Section 3.2, we first recall the notion of the CRT basis in the ring-LWE setting, and then develop an algebraic property of the CRT basis of  $\mathcal{R}_q$ , *i.e.*, Proposition 5, that are *essential* for our small field attack against the one-pass AKE scheme  $\Pi_1$  proposed in [ZZD<sup>+</sup>15, ZZDS14].

#### 3.1 The Ring-LWE Problem

Below are the preliminaries about ideal lattices and the ring-LWE problem. For the full detail, please refer to [LPR13a, LPR13b, DD12].

**The rings  $\mathcal{R}$  and  $\mathcal{R}_q$**  Let  $\zeta$  denote a primitive  $2n$ -th root of unity in  $\mathbb{C}$ , and its minimum polynomial over  $\mathbb{Q}$  is the  $2n$ -th cyclotomic polynomial  $\Phi_{2n}(x) \triangleq x^n + 1 \in \mathbb{Z}[x]$ . Let  $\mathcal{R} \triangleq \mathbb{Z}[\zeta]$  be the ring of integers of the number field  $\mathbb{Q}(\zeta)/\mathbb{Q}$ . Moreover, define the principal ideal  $\langle q \rangle = q\mathcal{R}$  and its associated quotient ring  $\mathcal{R}_q \triangleq \mathcal{R}/q\mathcal{R}$ . In this work, each coset of  $q\mathcal{R}$  in  $\mathcal{R}$  is naturally represented by a *unique* element in the set  $\left\{ \sum_{j \in [n]} u_j \zeta^{j-1} \mid u_j \in \mathbb{F}_q \right\}$ .

Since  $\zeta^0, \dots, \zeta^{n-1}$  constitute an  $\mathbb{F}_q$ -basis of the free  $\mathbb{F}_q$ -module  $\mathcal{R}_q$  of rank  $n$ , every  $\mathbf{u} = \sum_{j \in [n]} u_j \zeta^{j-1} \in \mathcal{R}_q$  could be identified with the (column) vector  $(u_1, \dots, u_n)^t = [u_j]_{j \in [n]} \in \mathbb{F}_q^n$ , *and vice versa*. Such identification is denoted as  $\mathbf{u} \sim [u_i]_{i \in [n]}$  in this work. Hence, every  $n$ -dimensional (column) vector in  $\mathbb{F}_q^n$  can be regarded as an element of  $\mathcal{R}_q$  in the *natural* way when necessary, *and vice versa*. It follows that the domain of the projection  $\mu_j(\cdot)$  defined previously could be generalized to  $\mathcal{R}_q$  in the sense that  $\mu_j\left(\sum_{j \in [n]} u_j \cdot \zeta^{j-1}\right) \triangleq u_j \in \mathbb{F}_q$  for

every  $j \in [n]$ . Moreover, let  $\mu(\mathbf{u}) \triangleq [\mu_j(\mathbf{u})]_{j \in [n]}$ , which induces an  $\mathbb{F}_q$ -module isomorphism. It is understood that  $\|\mathbf{u}\|_2 \triangleq \|\mu(\mathbf{u})\|_2$  and  $\|\mathbf{u}\|_\infty \triangleq \|\mu(\mathbf{u})\|_\infty$  for every  $\mathbf{u} \in \mathcal{R}_q$ . To emphasize this  $\mathbb{F}_q$ -module isomorphism, elements of  $\mathcal{R}_q$  are represented by lower-case bold letters in this work. In particular, let  $\mathbf{0}$  denote both the vector  $(0, \dots, 0)^t \in \mathbb{F}_q^n$  and the zero element of  $\mathcal{R}_q$  in the sequel, and it would be clear from the context.

**The discrete Gaussian distribution** Given the positive real  $\alpha > 0$ , define the real Gaussian function  $\rho_\alpha(x) \triangleq \exp(-x^2/2\alpha^2)/\sqrt{2\pi\alpha^2}$  for  $x \in \mathbb{R}$ . Let  $D_{\mathbb{Z},\alpha}$  denote the 1-dimensional *discrete* Gaussian distribution over  $\mathbb{Z}$ , determined by its density function  $D_{\mathbb{Z},\alpha}(x) = \rho_\alpha(x)/\rho_\alpha(\mathbb{Z})$ ,  $x \in \mathbb{Z}$ . Finally, let  $D_{\mathbb{Z}^n,\alpha}$  denote the  $n$ -dimensional *spherical* discrete Gaussian distribution over  $\mathbb{Z}^n$ , where each coordinate is drawn *independently* from  $D_{\mathbb{Z},\alpha}$ .

When  $\alpha = \omega(\sqrt{\log n})$ , *almost* every sample  $\varepsilon \leftarrow D_{\mathbb{Z}^n,\alpha}$  is “short” in the sense that  $\Pr[\|\varepsilon\|_2 \leq \alpha\sqrt{n}] = 1 - \text{negl}(\lambda)$  [Reg09,LPR13a]. For the “short” noise  $\varepsilon \leftarrow D_{\mathbb{Z}^n,\alpha}$ , it could be seen as an element of  $\mathcal{R}$  in the natural way; Moreover, when  $q > 1 + 2\alpha\sqrt{n}$ , *except with negligible probability*,  $\varepsilon$  could be considered to be an element of  $\mathbb{F}_q^n$  (and hence of  $\mathcal{R}_q$ ) in the *natural* way as well.

The following lemma implies that for several “short” noises in  $\mathcal{R}$ , their product is also “short”.

**Lemma 1.** *Let  $n = \text{poly}(\lambda) \geq 16$  be a power-of-two. If  $\alpha_i = \omega(\sqrt{\log n})$  and  $e_i \leftarrow D_{\mathbb{Z}^n,\alpha_i}$  for every  $i \in \{1, 2, 3\}$ , then every  $e_i$  could be regarded as an element of  $\mathcal{R}$  in the natural way with overwhelming probability; Moreover, the following inequalities hold with overwhelming probability:*

$$\|e_1 e_2\|_\infty \leq n \cdot \alpha_1 \alpha_2, \quad \|e_1 e_2 e_3\|_\infty \leq n^2 \cdot \alpha_1 \alpha_2 \alpha_3. \quad \square$$

**The ring-LWE (RLWE) problem** The following defines *only a special* case [DD12] of the *original* ring-LWE problem proposed in [LPR13a], since this special case, instead of the original one, serves as the underlying hard problem of both  $\Pi_1$  and  $\Pi_2$  [ZZDS14,ZZD<sup>+</sup>15], and suffices for the discussions in this work.

Each ring-LWE instance is parameterized by  $n = n(\lambda)$ ,  $q = q(\lambda)$  and  $\alpha = \alpha(\lambda)$ , where  $n \geq 16$  is a power-of-two,  $q$  is a positive rational prime such that  $q \equiv 1 \pmod{2n}$ , and  $\alpha \geq 0$ . For every (fixed)  $\mathbf{s} \in \mathcal{R}_q$ , we define the ring-LWE distribution  $A_{n,q,\alpha,\mathbf{s}}$  over  $\mathcal{R}_q \times \mathcal{R}_q$ : a sample drawn from  $A_{n,q,\alpha,\mathbf{s}}$  is generated by first choosing  $\mathbf{a} \leftarrow \mathcal{R}_q$ ,  $\varepsilon \leftarrow D_{\mathbb{Z}^n,\alpha}$ , and then outputting the *ring-LWE sample*  $(\mathbf{a}, \mathbf{b} \triangleq \mathbf{a}\mathbf{s} + \varepsilon) \in \mathcal{R}_q \times \mathcal{R}_q$  or equivalently  $(\mathbf{a}, \mathbf{b} = \mathbf{a}\mathbf{s} + 2\varepsilon)$  as in [ZZD<sup>+</sup>15].

**Definition 2 ([LPR13a,LPR13b,DD12]).** *For the ring-LWE problem, its search variant is defined as follows: given access to arbitrarily many independent samples drawn from  $A_{n,q,\alpha,\mathbf{s}}$  for some arbitrary  $\mathbf{s} \in \mathcal{R}_q$ , the problem asks to recover  $\mathbf{s} \in \mathcal{R}_q$ ; In contrast, the decisional variant asks to distinguish, with non-negligible advantage, between arbitrarily many independent samples from  $A_{n,q,\alpha,\mathbf{s}}$  for a random  $\mathbf{s} \leftarrow \mathcal{R}_q$ , and the same number of uniformly random and independent samples drawn from the set  $\mathcal{R}_q \times \mathcal{R}_q$ .*

It can be shown that for Definition 2, its decisional and search variants are *computationally equivalent*, under mild constraints on the parameters [LPR13a,DD12]. Furthermore, the hardness of (search/decisional) ring-LWE problem is implied by the following lemma.

**Theorem 3 ([LPR13a,DD12]).** *For the RLWE problem defined in Definition 2, if there is an efficient algorithm that can distinguish, with  $1/\text{poly}(\lambda)$  advantage, between  $\ell$  samples drawn from the uniform distribution over  $\mathcal{R}_q \times \mathcal{R}_q$  and  $\ell$  samples drawn from  $A_{n,q,\alpha,\mathbf{s}}$ , where  $\beta = \sqrt{n}\alpha q \cdot (n\ell/\log(n\ell))^{1/4}$ , then there exists an efficient quantum algorithm that runs in time  $O(q \cdot \text{poly}(m))$  and solves the approximate SVP problem to within a factor  $\tilde{O}(\sqrt{2n}/\alpha)$  in any ideal of  $\mathbb{Z}[\zeta]$ .  $\square$*

### 3.2 The CRT Basis of $\mathcal{R}_q$ and Its Properties

The notion of the CRT basis (in the ring-LWE setting) was first proposed in [LPR13a]. Here we first review its definition and basic properties; After that, we develop a new algebraic property, *i.e.*, Proposition 5, regarding the CRT basis of  $\mathcal{R}_q$ , which would be *essential* for our efficient attackers to be developed later.

When  $n, q$  are clear, let  $\{\omega_1, \dots, \omega_n\} \subseteq \mathbb{F}_q^\times \setminus \{\pm 1\}$  be the set of elements in  $\mathbb{F}_q^\times$  that are of multiplicative order  $2n$ . Since the polynomial  $\Phi_{2n}(x) \equiv \prod_{i \in [n]} (x - \omega_i) \pmod{q}$  is separable over  $\mathbb{F}_q$  by the assumption on parameters, the principal ideal  $q\mathcal{R}$  of  $\mathcal{R}$  could be factored as  $q\mathcal{R} = \prod_{i \in [n]} \mathfrak{q}_i$ , where every nonzero prime ideal  $\mathfrak{q}_i = \langle q, \zeta - \omega_i \rangle$  by a suitable ordering, and the norm of every  $\mathfrak{q}_i$  in  $\mathcal{R}$  is  $|\mathcal{R}/\mathfrak{q}_i| = q^{\deg(x - \omega_i)} = q$ . Hence, every quotient ring  $\mathcal{R}/\mathfrak{q}_i$  is a finite field of prime order  $q$ , indicating that  $\mathcal{R}/\mathfrak{q}_i \cong \mathbb{F}_q$ . Hence, the ring  $\mathcal{R}_q$  could be

identified with the direct product of  $n$  small finite field, each of prime order  $q = \text{poly}(\lambda)$ . This explains how our notion of small field attack bears its name.

As the *distinct* nonzero prime ideals  $\mathfrak{q}_1, \dots, \mathfrak{q}_n$  are necessarily pairwise coprime, it follows from the Chinese remainder theorem that  $\mathcal{R}_q = \mathcal{R}/q\mathcal{R} \cong \prod_{i \in [n]} \mathcal{R}/\mathfrak{q}_i$  under the *natural ring isomorphism*  $\mathbf{u} + q\mathcal{R} \mapsto (\mathbf{u} + \mathfrak{q}_1, \dots, \mathbf{u} + \mathfrak{q}_n)$ . Under the natural isomorphism, we can find  $n$  elements  $\mathbf{c}_1, \dots, \mathbf{c}_n \in \mathcal{R}$  such that  $\mathbf{c}_i \equiv \delta_{i,j} \pmod{\mathfrak{q}_j}$  for every  $i, j \in [n]$ , where  $\delta_{\cdot, \cdot}$  denotes the Kronecker delta function. The elements  $\mathbf{c}_1, \dots, \mathbf{c}_n \in \mathcal{R}$  form an *integral basis* of  $\mathcal{R}$  relative to  $\mathfrak{q}_1, \dots, \mathfrak{q}_n$ , and is called a *CRT basis* of  $\mathcal{R}$  relative to  $\mathfrak{q}_1, \dots, \mathfrak{q}_n$ . Moreover, it is easy to see for any two CRT bases of  $\mathcal{R}$  (relative to  $\mathfrak{q}_1, \dots, \mathfrak{q}_n$ ), they are *equivalent* up to mod  $q\mathcal{R}$ . In particular, when  $\mathbf{c}_1, \dots, \mathbf{c}_n$  fall into the set  $\mathcal{R}_q = \left\{ \sum_{j \in [n]} u_j \zeta^{j-1} \mid u_j \in \mathbb{F}_q \right\}$ , they form an  $\mathbb{F}_q$ -basis of the free  $\mathbb{F}_q$ -module  $\mathcal{R}_q$ ; By definition, this  $\mathbb{F}_q$ -basis is *unique* in  $\mathcal{R}_q$  up to ordering, which would be called *the CRT basis* of  $\mathcal{R}_q$  hereafter.

The basic properties of the CRT basis of  $\mathcal{R}_q$  are summarized as follows.

**Fact 4 ([LPR13a,LPR13b]).** For the CRT basis  $\{\mathbf{c}_1, \dots, \mathbf{c}_n\}$  of  $\mathcal{R}_q$ ,

- (a) Given  $n$  and  $q$  (in unary form), the CRT basis of  $\mathcal{R}_q$  could be found efficiently.
- (b) Every  $\mathbf{u} \in \mathcal{R}_q$  can be written uniquely as  $\mathbf{u} = \sum_{i \in [n]} u_i \cdot \mathbf{c}_i$ ,  $u_i \in \mathbb{F}_q$ .
- (c) Let  $\mathbf{u} = \sum_{i \in [n]} u_i \cdot \mathbf{c}_i$  and  $\mathbf{v} = \sum_{i \in [n]} v_i \cdot \mathbf{c}_i$ ,  $u_i, v_i \in \mathbb{F}_q$ . Then for every  $k \in \mathbb{F}_q$ , we have:

$$k \cdot \mathbf{u} = \sum (k \cdot u_i) \cdot \mathbf{c}_i, \quad \mathbf{u} + \mathbf{v} = \sum (u_i + v_i) \cdot \mathbf{c}_i, \quad \mathbf{u} \cdot \mathbf{v} = \sum (u_i \cdot v_i) \cdot \mathbf{c}_i. \square$$

Throughout this work, when  $n, q$  are clear from the context, let  $\{\mathbf{c}_1, \dots, \mathbf{c}_n\}$  denote the CRT basis of  $\mathcal{R}_q$ ; Moreover, define  $c_{i,j} \triangleq \mu_j(\mathbf{c}_i) \in \mathbb{F}_q$  for every  $i, j \in [n]$ . Thus, every  $\mathbf{c}_i = \sum_{j \in [n]} c_{i,j} \cdot \zeta^{j-1}$ .

With the CRT basis  $\{\mathbf{c}_1, \dots, \mathbf{c}_n\}$  of  $\mathcal{R}_q$  in mind, define the map  $\eta_i : \mathcal{R}_q \rightarrow \mathbb{F}_q$  for every  $i \in [n]$ , where  $\eta_i \left( \sum_{i \in [n]} (u_i \cdot \mathbf{c}_i) \right) \triangleq u_i$ ,  $u_i \in \mathbb{F}_q$ . Clearly, the map  $\eta_i(\cdot)$  is *well-defined* and *efficiently computable*. Every  $\eta_i(\mathbf{u})$  is called a *CRT-coefficient* of  $\mathbf{u} \in \mathcal{R}_q$ . Moreover, define the map  $\eta : \mathcal{R}_q \rightarrow \mathbb{F}_q^n$ , where  $\eta(\mathbf{u}) \triangleq [\eta_i(\mathbf{u})]_{i \in [n]}$  for every  $\mathbf{u} \in \mathcal{R}_q$ . Direct verification shows that  $\eta(\cdot)$  is a ring isomorphism, and is an  $\mathbb{F}_q$ -module isomorphism when both are regarded as free  $\mathbb{F}_q$ -modules.

For every  $\mathbf{u} \in \mathcal{R}_q$ , define  $\text{Dim}(\mathbf{u}) \triangleq \{i \in [n] \mid \eta_i(\mathbf{u}) \neq 0 \in \mathbb{F}_q\} \subseteq [n]$ , and the cardinality  $|\text{Dim}(\mathbf{u})| \in \{0, 1, \dots, n\}$  is called the *CRT-dimension* of  $\mathbf{u}$ .

We conclude this section by developing a new property of the CRT basis  $\{\mathbf{c}_1, \dots, \mathbf{c}_n\}$  of  $\mathcal{R}_q$ , which is *essential* for our SFA attacks against  $\Pi_1$ .

**Proposition 5.** With the notations defined previously, we have  $c_{i,j} = c_{i,n} \cdot \omega_i^{n-j} \neq 0 \in \mathbb{F}_q$  for every  $i, j \in [n]$ .

*Proof.* Fix  $i \in [n]$ . For the element  $\zeta \in \mathcal{R}$ , we have

$$\zeta + \mathfrak{q}_i = \zeta + \langle q, \zeta - \omega_i \rangle = \omega_i + \langle q, \zeta - \omega_i \rangle \in \mathcal{R}/\mathfrak{q}_i.$$

It follows that in the ring  $\mathcal{R}$ ,  $\zeta \equiv \omega_i \cdot \mathbf{c}_i \pmod{\mathfrak{q}_i}$ .

On the one hand, by Fact 4, we have that in  $\mathcal{R}_q$ ,

$$\zeta \cdot \mathbf{c}_i = \omega_i \cdot \mathbf{c}_i = \sum_{j \in [n]} (\omega_i \cdot c_{i,j}) \zeta^{j-1} \in \mathcal{R}_q.$$

On the other hand, the following equality holds in  $\mathcal{R}_q$ :

$$\begin{aligned} \zeta \cdot \mathbf{c}_i &= \zeta \cdot (c_{i,1} + c_{i,2}\zeta + \dots + c_{i,n}\zeta^{n-1}) \\ &= c_{i,n}\zeta^n + \sum_{j \in [n-1]} c_{i,j}\zeta^j \\ &= -c_{i,n} + \sum_{j \in [n-1]} c_{i,j}\zeta^j, \end{aligned}$$

where the equality  $0 = \Phi_{2n}(\zeta) = \zeta^n + 1 \in \mathcal{R}_q$  is implicitly applied.

As  $\zeta^0, \zeta, \dots, \zeta^{n-1}$  form an  $\mathbb{F}_q$ -basis of the  $\mathbb{F}_q$ -module  $\mathcal{R}_q$ , we have

$$c_{i,1} = \omega_i c_{i,2}, \quad \dots \quad c_{i,n-1} = \omega_i c_{i,n}, \quad -c_{i,n} = \omega_i c_{i,1};$$

Equivalently,  $c_{i,j} = c_{i,n} \cdot \omega_i^{n-j} \in \mathbb{F}_q$  for every  $j \in [n]$ .

If  $c_{i,n} = 0$ , then  $c_{i,j} = 0$  for every  $j \in [n]$ , making  $\mathbf{c}_i = \mathbf{0}$ , contradictory to the definition of the CRT basis of  $\mathcal{R}_q$ . It follows that  $c_{i,n} \neq 0$ , and hence  $c_{i,j} \neq 0$  for every  $j \in [n]$ . And the correctness of this theorem is thus established.  $\square$

## 4 How to Attack $\Pi_1$ : a Warm-up

We first review the one-pass AKE scheme  $\Pi_1$  [ZZDS14,ZZD<sup>+</sup>15] in Section 4.1; Then in Section 4.2, the honest party  $j$  in  $\Pi_1$  is abstracted as an oracle  $\mathcal{M}_0$  with private key, such that to efficiently recover the static private key of party  $j$  in  $\Pi_1$ , it suffices to show how to recover the private key of  $\mathcal{M}_0$  efficiently, *provided that adversaries are allowed to register public keys on behalf of dishonest users*.

### 4.1 The One-Pass AKE Scheme $\Pi_1$

The one-pass AKE scheme  $\Pi_1$  [ZZDS14,ZZD<sup>+</sup>15] is built upon the RLWE problem in Definition 2, where every RLWE sample is of the form  $(\mathbf{a}, \mathbf{a}\mathbf{s} + 2\mathbf{e})$ .

In  $\Pi_1$ ,  $\mathbf{a} \leftarrow \mathcal{R}_q$  is a global public parameter, and  $M > 0$  is a sufficiently large constant. As a two-party AKE scheme, users in  $\Pi_1$  are represented by party  $i$  (*i.e.*, the initiator) and party  $j$  (*i.e.*, the responder), respectively. For party  $i$ : the static private key is  $(\mathbf{s}_i, \mathbf{e}_i)$ , where  $\mathbf{s}_i, \mathbf{e}_i \leftarrow D_{\mathbb{Z}^n, \alpha}$ ; Its associated static public key is  $\mathbf{p}_i \triangleq \mathbf{a}\mathbf{s}_i + 2\mathbf{e}_i \in \mathcal{R}_q$ ; And its identity issued by the Certificate Authority (CA) is  $\text{id}_i$ . Similar notations,  $\mathbf{s}_j, \mathbf{e}_j \leftarrow D_{\mathbb{Z}^n, \alpha}$ ,  $\mathbf{p}_j \triangleq \mathbf{a}\mathbf{s}_j + 2\mathbf{e}_j \in \mathcal{R}_q$ , and  $\text{id}_j$ , apply to party  $j$ . Let  $H_1 : \{0, 1\}^* \rightarrow D_{\mathbb{Z}^n, \gamma}$  be a hash function that outputs *invertible* elements in  $\mathcal{R}_q$ , and  $H_2 : \{0, 1\}^* \rightarrow \{0, 1\}^*$  be the key derivation function. Both  $H_1$  and  $H_2$  are regarded as random oracles in  $\Pi_1$ .

The following functions are essential for the definition of  $\Pi_1$ . First, When the prime  $q$  is clear from the context, define the function Parity :  $\mathbb{F}_q \rightarrow \{0, 1\}$ , where Parity  $(u) \triangleq u \pmod{2} \in \{0, 1\}$ . Moreover, we define the function Mod :  $\mathbb{F}_q \times \{0, 1\} \rightarrow \{0, 1\}$ , where Mod  $(u, w) \triangleq \text{Parity}((u + w \cdot q_0) \pmod{q}) \in \{0, 1\}$ . Finally, define the function Cha :  $\mathbb{F}_q \rightarrow \{0, 1\}$ , such that Cha  $(u) = 0$  if and only if  $u \in \{-\frac{q-1}{4}, \dots, \frac{q-1}{4}\}$ ; Otherwise, Cha  $(u) = 1$ . All these functions could be easily generalized to the  $n$ -dimensional case *in the component-wise manner*.

The following fact is *essential* both for  $\Pi_1$  and for our small field attack.

**Fact 6.** For every  $u \in \mathbb{F}_q$ ,

- (a) We always have  $v \triangleq u + \text{Cha}(u) \cdot q_0 \in \{-q_0/2, \dots, +q_0/2\} \subseteq \mathbb{F}_q$ .
- (b) The value Parity  $(v) = \text{Mod}(u, \text{Cha}(u)) \in \mathbb{B}$  is immune to a short even noise in the sense that

$$\text{Parity}(v) = \text{Parity}(v + 2e)$$

for every  $-q_0/4 < e < q_0/4$ .

- (c) The value Parity  $(v) = \text{Mod}(u, \text{Cha}(u)) \in \mathbb{B}$  is sensitive to a short odd noise in the sense that

$$\text{Parity}(v + 2e - 1) \neq \text{Parity}(v) \neq \text{Parity}(v + 2e + 1)$$

for every  $-q_0/4 < e < q_0/4$ .  $\square$

The one-pass scheme  $\Pi_1$  can be roughly described in Figure 4.1 [ZZDS14,ZZD<sup>+</sup>15].

**Correctness analysis of  $\Pi_1$**  Roughly speaking, the correctness of this scheme states that  $\text{sk}_i = \text{sk}_j$  holds *w.o.p.* On the one hand, since  $H_2(\cdot)$  is modeled as a random oracle and  $\text{id}_i, \text{id}_j, \mathbf{x}_i, \mathbf{w}_i$  are known to both parties, it suffices to show the equality  $\sigma_i = \sigma_j$  holds *w.o.p.* On the other hand, it is routine to verify

$$\mathbf{k}_i - \mathbf{k}_j = 2 \cdot (\mathbf{c}\mathbf{s}_i\mathbf{e}_j + \mathbf{r}_i\mathbf{e}_j + \mathbf{g}_i - \mathbf{c}\mathbf{e}_i\mathbf{s}_j - \mathbf{f}_i\mathbf{s}_j - \mathbf{c}\mathbf{g}_j).$$

By Lemma 1,  $\|\mathbf{k}_i - \mathbf{k}_j\|_\infty \leq 2(n\alpha\gamma + \beta\sqrt{n} + 2n\alpha\beta + 2n^2\alpha^2\gamma)$  holds *w.o.p.* Thus, when  $q$  is sufficiently large,  $\|\mathbf{k}_i - \mathbf{k}_j\|_\infty < q_0/2$  holds *w.o.p.* It follows from Fact 6(b) that  $\sigma_i = \text{Mod}(\mathbf{k}_i, \text{Cha}(\mathbf{k}_i)) = \text{Mod}(\mathbf{k}_j, \text{Cha}(\mathbf{k}_i)) = \sigma_j$  holds *w.o.p.* This finishes the correctness analysis of  $\Pi_1$ .

**Fig. 3.** General description of  $\Pi_1$ . Note that in the *full* description of  $\Pi_1$  in [ZZDS14,ZZD<sup>+</sup>15], party  $i$  applies the rejection sampling to generate a “good”  $(\mathbf{x}_i, \mathbf{w}_i)$  pair. Since the efficient attacker always generates his queries *dishonestly*, this technical detail does not affect our analysis and hence is omitted here for simplicity.

Clearly Lemma 1 is *essential* for the correctness of  $\Pi_1$ . However, when  $n$  is *not* a power-of-two, or  $q \not\equiv 1 \pmod{2n}$ , inequalities in Lemma 1 may *no longer* hold, which implies the underlying hard problem of  $\Pi_1$  *must be* Definition 2, a *special* case of the original ring-LWE problem defined in [LPR13a,LPR13b].

**Security analysis of  $\Pi_1$**  It is claimed in [ZZDS14,ZZD<sup>+</sup>15] that when  $n$  is a power-of-two,  $0.97n \geq 2\lambda$ ,  $\beta = \omega(\alpha\gamma n\sqrt{n\log n})$ , the prime  $q > 203$  satisfies  $q \equiv 1 \pmod{2n}$ , if the associated ring-LWE problem is “hard”, then  $\Pi_1$  is *secure*. In addition, four groups of parameters are suggested in [ZZD<sup>+</sup>15,ZZDS14] to instantiate  $\Pi_1$ . For instance, in one *typical* group of suggested parameters,  $n = 1024, q \approx 2^{30}, \alpha = 3.397, \beta \approx 2^{16.1}, \gamma = \alpha$ .

## 4.2 Definition of the Oracle $\mathcal{M}_0$

First, notice that in  $\Pi_1$ , the session key derivation function  $H_2(\cdot)$  is modeled as an random oracle. Moreover, notice that every time party  $j$  generates its session key by invoking  $\text{sk}_j \triangleq H_2(\text{id}_i, \text{id}_j, \mathbf{x}_i, \mathbf{w}_i, \sigma_j)$ , *all the input values except  $\sigma_j$*  are known to party  $i$ . It follows that *except with negligible probability*, if party  $i$  is able to figure out the session key  $\text{sk}_j$  of party  $j$  correctly *before* it issues the associated session-key query to party  $j$ , then party  $i$  must be able to figure out the associated  $\sigma_j$  *beforehand, and vice versa*.

Now we can define an oracle  $\mathcal{M}_0$  with private key, which aims to simulate some valid functionalities of party  $j$  in  $\Pi_1$ . The private key of  $\mathcal{M}_0$  is  $(s, e)$  and the associated public key is  $\mathbf{p}$ , where  $s, e \leftarrow D_{\mathbb{Z}^n, \alpha}$  and  $\mathbf{p} \triangleq \mathbf{a} \cdot s + 2e \in \mathcal{R}_q$  (recall that  $\mathbf{a} \leftarrow \mathcal{R}_q$  is a global parameter in  $\Pi_1$ ). Moreover, as a simulator of party  $j$ , the identifier of  $\mathcal{M}_0$  is denoted by  $\text{id}$ . On input  $(\text{id}^*, \mathbf{p}^*, \mathbf{x}, \mathbf{w}, z)$ , where  $\mathbf{x} \in \mathcal{R}_q, z, \mathbf{w} \in \mathbb{B}^n$ , and  $\text{id}^*$  denotes the identifier of the initiator with public key  $\mathbf{p}^* \in \mathcal{R}_q$ ,  $\mathcal{M}_0$  does the following: it first samples  $\mathbf{g} \leftarrow D_{\mathbb{Z}^n, \alpha}$ , then computes  $\mathbf{c} \leftarrow H_1(\text{id}^*, \text{id}, \mathbf{x}), \mathbf{k} := (\mathbf{p}^*\mathbf{c} + \mathbf{x})s + q_0\mathbf{w} + 2\mathbf{c}\mathbf{g}$ , and  $\sigma := \text{Parity}(\mathbf{k}) \in \mathbb{B}^n$ ; Finally,  $\mathcal{M}_0$  returns 1 if and only if  $z = \sigma$ . Equivalently, in every session interaction party  $i$  could get from party  $j$  only one bit of information, *i.e.*, whether the session-key returned by party  $j$  is equal to the expected one or not. As clarified in Section 1.2, such one-bit oracle is always available in practice.

We shall construct, in Section 6, an efficient attacker  $\mathcal{A}_0$  that can recover the private key  $(s, e)$  of  $\mathcal{M}_0$ , *provided that  $\mathcal{A}_0$  can register its public/private key pair on its own*; Moreover, the desired  $\mathcal{A}_0$  is carefully designed such that both its public key and those queries it makes are as “random-looking” as possible. Clearly the existence of  $\mathcal{A}_0$  implies the vulnerability of  $\Pi_1$ . Nevertheless, given the “complexity” of  $\mathcal{A}_0$ , we shall define, in Section 4.3, a simplified variant of  $\mathcal{M}_0$ , *i.e.*,  $\mathcal{M}_1$ , and see how to construct an efficient attacker against  $\mathcal{M}_1$ .

### 4.3 Oracle $\mathcal{M}_1$ and Its Associated Efficient Attacker $\mathcal{A}_1$

For the moment, we assume that there exists an efficient attacker against  $\mathcal{M}_0$  with public key  $\mathbf{p}^* = \mathbf{0} \in \mathcal{R}_q$ . By definition, for the input  $(\text{id}^*, \mathbf{p}^* = \mathbf{0}, \mathbf{x}, \mathbf{w}, \mathbf{z})$  made by this attacker,  $\mathcal{M}_0$  first samples  $\mathbf{g} \leftarrow D_{\mathbb{Z}^n, \alpha}$ , then computes  $\mathbf{c} \leftarrow H_1(\text{id}^*, \text{id}, \mathbf{x})$ ,  $\mathbf{k} := (\mathbf{p}^* \mathbf{c} + \mathbf{x})\mathbf{s} + q_0 \mathbf{w} + 2\mathbf{c}\mathbf{g} = \mathbf{x}\mathbf{s} + q_0 \mathbf{w} + 2\mathbf{c}\mathbf{g}$ , and  $\sigma := \text{Parity}(\mathbf{k}) \in \mathbb{B}^n$ ; Finally,  $\mathcal{M}_0$  returns 1 if and only if  $\mathbf{z} = \sigma$ . Notice that  $\|\mathbf{c}\mathbf{g}\|_\infty \leq n \cdot \alpha\gamma$  by Lemma 1.

This simplified analysis motivates us to define the oracle  $\mathcal{M}_1$  with secret  $\mathbf{s} \leftarrow D_{\mathbb{Z}^n, \alpha}$ : on input  $(\mathbf{x}, \mathbf{w}, \mathbf{z} = [z_j]_{j \in [n]}) \in \mathcal{R}_q \times \mathbb{B}^n \times \mathbb{B}^n$ , the oracle  $\mathcal{M}_1$  first generates a small error  $\varepsilon \leftarrow \mathbb{Z}_{1+2\theta}^n = \{-\theta, \dots, \theta\}^n$ , and then computes  $\sigma \triangleq \text{Parity}(\mathbf{x}\mathbf{s} + q_0 \mathbf{w} + 2\varepsilon) = [\sigma_j]_{j \in [n]}$ , and finally returns 1 if and only if  $[\sigma_j]_{j \in [n]} = [z_j]_{j \in [n]}$ ; Otherwise, 0 is returned. Here,  $\theta > 0$  is a constant parameter.

Clearly,  $\mathcal{M}_1$  could be seen as a simplified variant of  $\mathcal{M}_0$  when  $\theta = n\alpha\gamma$ . Next, we are devoted to the construction of an *efficient* attacker  $\mathcal{A}_1$  that, given oracle access to  $\mathcal{M}_1$ , can recover the secret of  $\mathcal{M}_1$  *w.o.p.*

**The CRT basis w.r.t.  $\mathcal{A}_1$**  The construction of  $\mathcal{A}_1$  could be seen as a simple application of the CRT basis  $\{\mathbf{c}_1, \dots, \mathbf{c}_n\}$  of  $\mathcal{R}_q$ . Recall that with  $\{\mathbf{c}_1, \dots, \mathbf{c}_n\}$  that is efficiently computable, every element  $\mathbf{u} \in \mathcal{R}_q$  can be *uniquely* written as  $\mathbf{u} = \sum_{i \in [n]} \eta_i(\mathbf{u}) \cdot \mathbf{c}_i$ ; Moreover, we have  $\mathbf{u}\mathbf{v} = \sum_{i \in [n]} \eta_i(\mathbf{u})\eta_i(\mathbf{v}) \cdot \mathbf{c}_i$  for every  $\mathbf{u}, \mathbf{v} \in \mathcal{R}_q$ . Thus, to recover  $\mathbf{s} \in \mathcal{R}_q$ , it suffices to recover all of its CRT-coefficients  $s_i \triangleq \eta_i(\mathbf{s}) \in \mathbb{F}_q, i \in [n]$ . Furthermore, notice that for every query  $(\mathbf{x}, \mathbf{w}, \mathbf{z})$  made to  $\mathcal{M}_1$ , if  $\mathbf{x} = k \cdot \mathbf{c}_i$  for some  $k \in \mathbb{F}_q, i \in [n]$ , then we have  $\mathbf{x}\mathbf{s} = ks_i \cdot \mathbf{c}_i$ ; In such setting, the product  $\mathbf{x}\mathbf{s}$  always falls into a subfield  $\{k\mathbf{c}_i \mid k \in \mathbb{F}_q\}$  of  $\mathcal{R}_q$ , which is of “small” size  $q = \text{poly}(\lambda)$ , making it possible for us to recover every  $s_i \in \mathbb{F}_q$  separately.

**General structure of  $\mathcal{A}_1$**  The previous analysis implies the *general structure* of our desired  $\mathcal{A}_1$  is as follows: the main body of  $\mathcal{A}_1$  consist of an  $n$ -round loop, and the  $i$ -th round is devoted to the recovery of  $s_i = \eta_i(\mathbf{s}) \in \mathbb{F}_q, i \in [n]$ ; In the  $i$ -th round, given  $s_1, \dots, s_{i-1}$  and oracle access to  $\mathcal{M}_1$ , it first picks  $\tilde{s}_i \leftarrow \mathbb{F}_q$  randomly, guesses  $s_i = \tilde{s}_i \in \mathbb{F}_q$ , and then verifies the correctness of this guess via a set  $\mathcal{Q}_i(\tilde{s}_i)$  of queries to  $\mathcal{M}_1$ ; The set  $\mathcal{Q}_i(\tilde{s}_i)$  should be carefully chosen such that the distribution of these query replies under the condition  $s_i = \tilde{s}_i$  is *computationally distinguishable* from that under the condition  $s_i \neq \tilde{s}_i$ ; Thus, the exact value of  $s_i \in \mathbb{F}_q$  would be recovered *w.o.p.* after  $\tilde{s}_i$  runs over the set  $\mathbb{F}_q$ .

**Design of  $\mathcal{Q}_i(\tilde{s}_i)$**  For the moment, assume  $s_1, \dots, s_{i-1}$  have been recovered *successfully* and  $\tilde{s}_i \in \mathbb{F}_q$  is fixed, and we are devoted to verifying the correctness of the guess  $s_i = \tilde{s}_i$  by designing the *desired* query set  $\mathcal{Q}_i(\tilde{s}_i)$ . Jumping ahead,

$$\mathcal{Q}_i(\tilde{s}_i) = \left\{ Q_k \triangleq (\mathbf{x}_k = k\mathbf{c}_i, \mathbf{w}_k = [w_{k,j}]_{j \in [n]}, \mathbf{z}_k = [z_{k,j}]_{j \in [n]}) \mid k \in S \subseteq \mathbb{F}_q^\times \right\},$$

where  $S$  is a nonempty proper subset of  $\mathbb{F}_q^\times$  to be defined later. It remains to specify the  $\mathbf{w}$ - and  $\mathbf{z}$ -entries of every query in  $\mathcal{Q}_i(\tilde{s}_i)$ .

For the moment, we assume  $s_i = \tilde{s}_i$ . In such case, for the query  $Q_k = (k\mathbf{c}_i, \mathbf{w}_k, \mathbf{z}_k) \in \mathcal{Q}_i(\tilde{s}_i)$ , if  $w_{k,j} = \text{Cha}(\mu_j(k\tilde{s}_i\mathbf{c}_i))$  for every  $j \in [n]$ , then every  $\mu_j(k\mathbf{c}_i\mathbf{s} + q_0\mathbf{w}_k)$  into the “secure zone”  $\text{zone}_0$  by Fact 6(a); Moreover, when every  $\mu_j(k\mathbf{c}_i\mathbf{s} + q_0\mathbf{w}_k) \in \text{zone}_0$ , Fact 6(b) guarantees that the *small and even* noise  $2\varepsilon$  does not affect the parity values, provided that  $\theta$  is “small” relative to  $q$ ; Therefore,  $\mathcal{M}_1$  would return 1 on  $Q_k$  if  $\mathbf{z}_k = \text{Mod}(k\mathbf{c}_i, \mathbf{w}_k) = \text{Parity}(k\mathbf{c}_i\mathbf{s} + q_0\mathbf{w}_k)$ . Conversely, if  $s_i \neq \tilde{s}_i$ , then some of the associated equalities may not hold *intuitively*. The following lemma justifies the correctness of this intuition.

**Lemma 7.** *Let  $g \in \mathbb{F}_q^\times$  denote a primitive element of  $\mathbb{F}_q$ , and let  $S_g \triangleq \{g^r \mid r \in [d]\}$  and  $d \triangleq \frac{q-1}{2n}$ . Define*

$$\mathcal{Q}_i(\tilde{s}_i) = \left\{ Q_k = (k\mathbf{c}_i, [w_{k,j}]_{j \in [n]}, [z_{k,j}]_{j \in [n]}) \mid \begin{array}{l} k \in S_g, j \in [n], u_{k,j} = \tilde{s}_i \cdot kc_{i,j}, \\ w_{k,j} = \text{Cha}(u_{k,j}), z_{k,j} = \text{Mod}(u_{k,j}, w_{k,j}) \end{array} \right\}.$$

*If  $q > 1 + \max\{8\theta, 2\alpha\sqrt{n}\}$ , then except with negligible probability,  $s_i = \tilde{s}_i$  if and only if  $\mathcal{M}_1$  returns 1 on every query in  $\mathcal{Q}_i(\tilde{s}_i)$ .*

*Proof.* Throughout the proof, we assume that  $\mathbf{s} \in \mathcal{R}_q$ , which occurs *w.o.p.* by the assumption  $q > 1 + 2\alpha\sqrt{n}$ . Also, we only consider the case when the primitive element  $g \in \mathbb{F}_q^\times$  satisfies  $g^d = \omega_i$ , and the other cases are similar. Finally, let  $\Delta s_i \triangleq s_i - \tilde{s}_i \in \mathbb{F}_q$ , and hence  $s_i = \tilde{s}_i$  if and only if  $\Delta s_i = 0$ .

Recall that for the query  $Q_k = (\mathbf{x}_k = k \cdot \mathbf{c}_i, \mathbf{w}_k = [w_{k,j}]_{j \in [n]}, \mathbf{z}_k = [z_{k,j}]_{j \in [n]}) \in \mathcal{Q}_i(\tilde{s}_i)$ ,  $\mathcal{M}_1$  first generates  $\varepsilon_k \leftarrow \mathbb{Z}_{1+2\theta}^n$ , and then computes

$$\mathbf{v}_k \triangleq \mathbf{x}_k \cdot \mathbf{s} + q_0 \cdot \mathbf{w}_k + 2\varepsilon_k = ks_i \cdot \mathbf{c}_i + q_0 \cdot \mathbf{w}_k + 2\varepsilon_k$$

$$\begin{aligned}
& \sim \begin{bmatrix} s_i \cdot k \cdot c_{i,1} + q_0 \cdot w_{k,1} \\ \vdots \\ s_i \cdot k \cdot c_{i,n} + q_0 \cdot w_{k,n} \end{bmatrix} + \begin{bmatrix} 2\varepsilon_{k,1} \\ \vdots \\ 2\varepsilon_{k,n} \end{bmatrix} \quad (\varepsilon_{k,j} \triangleq \mu_j(\varepsilon_k)) \\
& = \begin{bmatrix} \Delta s_i \cdot k c_{i,1} + (\tilde{s}_i \cdot k \cdot c_{i,1} + q_0 \cdot w_{k,1}) \\ \vdots \\ \Delta s_i \cdot k c_{i,n} + (\tilde{s}_i \cdot k \cdot c_{i,n} + q_0 \cdot w_{k,n}) \end{bmatrix} + \begin{bmatrix} 2\varepsilon_{k,1} \\ \vdots \\ 2\varepsilon_{k,n} \end{bmatrix} \\
& = \begin{bmatrix} \Delta s_i \cdot k c_{i,1} + u_{k,1} + \text{Cha}(u_{k,1}) \cdot q_0 \\ \vdots \\ \Delta s_i \cdot k c_{i,n} + u_{k,n} + \text{Cha}(u_{k,n}) \cdot q_0 \end{bmatrix} + \begin{bmatrix} 2\varepsilon_{k,1} \\ \vdots \\ 2\varepsilon_{k,n} \end{bmatrix};
\end{aligned}$$

Finally,  $\mathcal{M}_1$  returns 1 if  $\text{Parity}(v_{k,j}) = z_{k,j}$  for every  $j \in [n]$ , where  $v_{k,j} \triangleq \mu_j(\mathbf{v}_k)$ ; Otherwise,  $\mathcal{M}_1$  returns 0.

Notice that we always have  $u_{k,j} + \text{Cha}(u_{k,j}) \cdot q_0 \in \text{zone}_0$  by Fact 6(a). Also, it follows from the inequality  $q > 1 + 8\theta$  that we have  $-q_0/2 < 2\varepsilon_{k,j} < q_0/2$ .

First consider the simple case when  $\Delta s_i = 0$ . Since the short even noise  $2\varepsilon_{k,j}$  satisfy  $-q_0/2 < 2\varepsilon_{k,j} < q_0/2$ , according to Fact 6(b), it is routine to verify that  $\mathcal{M}_1$  returns 1 on every  $Q_k$  by definition.

In the sequel, we assume  $\Delta s_i \neq 0$ . Define the set

$$\text{offset}(\Delta s_i) \triangleq \{\Delta s_i \cdot k c_{i,j} \mid k \in S_g, j \in [n]\},$$

and we *claim* that  $\{-1, 1\} \cap \text{offset}(\Delta s_i) \neq \emptyset$ , i.e., either  $1 \in \text{offset}(\Delta s_i)$  or  $-1 \in \text{offset}(\Delta s_i)$ . Since  $c_{i,j} = c_{i,n} \cdot \omega_i^{n-j}$  by Proposition 5, we have

$$\Delta s_i \cdot k \cdot c_{i,j} = \Delta s_i c_{i,n} \cdot k \cdot \omega_i^{n-j}.$$

Let  $\Delta s_i c_{i,n} = g^{e^*}$  where  $e^* \in [q-1]$ . Clearly there exists a  $r^* \in [d]$  such that  $d \mid (e^* + r^*)$ , and  $(e^* + r^*)/d \in [2n]$ . Let  $k^* \triangleq g^{r^*} \in S_g$ . Then

$$\Delta s_i c_{i,n} \cdot k^* \cdot \omega_i^{n-j} = g^{e^* + r^*} \cdot \omega_i^{n-j} = \omega_i^{(e^* + r^*)/d + n - j}.$$

It is easy to see there exists a  $j^* \in [n]$  such that either  $(e^* + r^*)/d + n - j^* \equiv n \pmod{2n}$  or  $(e^* + r^*)/d + n - j^* \equiv 0 \pmod{2n}$ , or equivalently, either  $\Delta s_i \cdot c_{i,n} \cdot k^* \cdot \omega_i^{n-j^*} = \omega_i^n = -1 \in \mathbb{F}_q$  or  $\Delta s_i \cdot c_{i,n} \cdot k^* \cdot \omega_i^{n-j^*} = \omega_i^0 = 1 \in \mathbb{F}_q$ .

When  $\Delta s_i \cdot k^* \cdot c_{i,j^*} = \pm 1$ , it is easy to verify that  $z_{k^*,j^*} \neq \text{Parity}(v_{k^*,j^*})$  by Fact 6(c). Equivalently, the associated  $j^*$ -th equality of  $Q_{k^*}$  does not hold, and  $\mathcal{M}_1$  returns 0 on the query  $Q_{k^*} \in \mathcal{Q}_i(\tilde{s}_i)$ .  $\square$

The following theorem follows immediately from Lemma 7.

**Theorem 8.** *When  $q > 1 + \max\{8\theta, 2\alpha\sqrt{n}\}$ , the efficient attacker  $\mathcal{A}_1$  defined previously can recover the secret  $s$  of  $\mathcal{M}_1$  with overwhelming probability, by making at most  $n \cdot q \cdot \frac{q-1}{2n} = \text{poly}(\lambda)$  queries to  $\mathcal{M}_1$ .  $\square$*

**Remarks** First, the proof of Lemma 7 implies that the exact distribution form of the noise term  $\varepsilon$  generated by  $\mathcal{M}_1$  does not affect the correctness of  $\mathcal{A}_1$ ; Only its support does. This explains why the noise term in  $\mathcal{M}_1$  is simply defined to be drawn from the *uniform* distribution over its support  $\mathbb{Z}_{1+2\theta}^n$ . Moreover, it is not hard to see that the index set  $S_g = \{g^r \mid r \in [d]\}$  could be replaced by *any* complete system of representatives of cosets in the quotient group  $\mathbb{F}_q^\times/H$ , where  $H \triangleq \langle \omega_i \rangle$  is the *unique* subgroup of the cyclic  $\mathbb{F}_q^\times$  satisfying  $|H| = 2n$ . All these observations show that our attack against  $\mathcal{M}_1$  is *versatile*.

The success of  $\mathcal{A}_1$  relies heavily on the notion of the CRT basis  $c_1, \dots, c_n$  of  $\mathcal{R}_q$  as well as its property, which explains why our attackers ( $\mathcal{A}_1$  as well as its improved variants) are called *small field attackers*. Computer experiments have justified the correctness of our small field attacker  $\mathcal{A}_1$  against  $\mathcal{M}_1$ ; In particular,  $\mathcal{A}_1$  succeeds when the oracle  $\mathcal{M}_1$  is instantiated with these four groups of suggested parameters in [ZZD<sup>+</sup>15, ZZDS14] ( $\theta := n\alpha\gamma$ ).

The existence of  $\mathcal{A}_1$  implies that there exists an efficient attacker with public key  $\mathbf{0} \in \mathcal{R}_q$  that can recover the private key of  $\mathcal{M}_0$  *w.o.p.* Hence,  $\mathcal{A}_1$  itself suffices to show the vulnerability of  $\Pi_1$ .

**Motivating question #1** The success of  $\mathcal{A}_1$  relies on the assumption that  $\mathcal{M}_1$  imposes no restrictions on the incoming queries. Intuitively, for every query made by  $\mathcal{A}_1$ , the *w*- and *z*-entries seem “random” enough; However, the algebraic structure of *x*-entry is rather simple, as the *x*-entry always falls into the set  $\{k c_i \mid k \in \mathbb{F}_q, i \in [n]\}$  with size  $nq \ll q^n$ . Hence, it is easy for  $\mathcal{M}_1$  to identify those malicious queries made by  $\mathcal{A}_1$ , and the attacker

$\mathcal{A}_1$  will no longer work if the oracle  $\mathcal{M}_1$  additionally requires that  $\mathbf{x} \notin \{k\mathbf{c}_i \mid k \in \mathbb{F}_q, i \in [n]\}$ . Such *additional* requirement seems *reasonable*, given that  $nq \ll q^n$ .

Thus, our *first motivating question* arises: can we improve  $\mathcal{A}_1$  so that it can still recover the secret of  $\mathcal{M}_1$ , even if the aforementioned requirement is imposed by  $\mathcal{M}_1$ ? The answer is affirmative, as we shall see in Section 5.

## 5 Making Small Field Attack “Undetectable”

In this section, we continue our analysis on the oracle  $\mathcal{M}_1$ , and show that we can construct an efficient hybrid attacker  $(\mathcal{V}/\mathcal{A}'_1)_\delta$  against  $\mathcal{M}_1$ , whose malicious queries are as “random-looking” as possible.

### 5.1 The Improved Attacker $\mathcal{A}'_1$ Against $\mathcal{M}_1$

The construction of  $\mathcal{A}'_1$  relies on the following two observations. First, recall that in the  $i$ -th round of  $\mathcal{A}_1$ ,  $s_1, \dots, s_{i-1} \in \mathbb{F}_q$  are assumed to be known already. Thus, we can use these known CRT-coefficients of  $\mathbf{s} \in \mathcal{R}_q$  to re-design the  $\mathbf{x}$ -entry so that it looks much more “complex”. Moreover, by Lemma 1, the attack still succeeds if we add a “small” *even* noise into the  $\mathbf{x}$ -entry, *provided that  $q$  is sufficiently large*. In sum, in the  $i$ -th round, for every query made by  $\mathcal{A}'_1$  to  $\mathcal{M}_1$ , the  $\mathbf{x}$ -entry is of the form

$$\mathbf{x} = k\mathbf{c}_i + \mathbf{h} + 2\mathbf{e},$$

where  $\mathbf{h} \leftarrow \{\mathbf{u} \in \mathcal{R}_q \mid \text{Dim}(\mathbf{u}) = [i-1]\}$ , and  $\mathbf{e} \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ . Intuitively, the introduction of  $\mathbf{h}$ - and  $\mathbf{e}$ -parts into the  $\mathbf{x}$ -entry is to make the queries made by  $\mathcal{A}'_1$  as “random-looking” as possible. Of course, this improvement asks us to re-design the settings of  $\mathbf{w}$ - and  $\mathbf{z}$ -entries appropriately.

The aforementioned improvement implies the desired  $\mathcal{A}'_1$ : its general structure is similar to that of  $\mathcal{A}_1$ , and the only difference lies in the definition of the query set in each round. The following lemma characterizes the query set  $\mathcal{Q}'_i(\tilde{s}_i)$  used by  $\mathcal{A}'_1$  in its  $i$ -th round.

**Lemma 9.** *Let  $g \in \mathbb{F}_q^\times$  denote a primitive element of  $\mathbb{F}_q$ , and let  $S_g \triangleq \{g^r \mid r \in [d]\}$  and  $d \triangleq \frac{q-1}{2n}$ . Define*

$$\mathcal{Q}'_i(\tilde{s}_i) = \left\{ Q'_k = \left( k \cdot \mathbf{c}_i + \mathbf{h}_k + 2\mathbf{e}_k, [w_{k,j}]_{j \in [n]}, [z_{k,j}]_{j \in [n]} \right) \left| \begin{array}{l} k \in S_g, j \in [n], h_{k,1}, \dots, h_{k,i-1} \leftarrow \mathbb{F}_q^\times, \\ \mathbf{h}_k = \sum_{r \in [i-1]} h_{k,r} \mathbf{c}_r, \mathbf{e}_k \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n, \\ u_{k,j} = \tilde{s}_i \cdot k\mathbf{c}_{i,j} + \sum_{r \in [i-1]} s_r h_{k,r} \mathbf{c}_{r,j}, \\ w_{k,j} = \text{Cha}(u_{k,j}), z_{k,j} = \text{Mod}(u_{k,j}, w_{k,j}) \end{array} \right. \right\}.$$

*If  $q > 1 + 8(\theta + n\alpha\alpha')$ , then except with negligible probability,  $s_i = \tilde{s}_i$  if and only if  $\mathcal{M}_1$  returns 1 on every query in  $\mathcal{Q}'_i(\tilde{s}_i)$ .*

*Proof.* Let  $\Delta s_i \triangleq s_i - \tilde{s}_i \in \mathbb{F}_q$ . Moreover, for  $\mathbf{s} \leftarrow D_{\mathbb{Z}^n, \alpha}$  and  $\mathbf{e}_k \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ , define  $\varepsilon'_k \triangleq \mathbf{s} \cdot \mathbf{e}_k \in \mathcal{R}_q$ ; By Lemma 1, the inequality  $\|\varepsilon'_k\|_\infty \leq n\alpha\alpha'$  holds *w.o.p.*

For the query  $Q'_k = (\mathbf{x}_k = k \cdot \mathbf{c}_i + \mathbf{h}_k + 2\mathbf{e}_k, \mathbf{w}_k = [w_{k,j}]_{j \in [n]}, \mathbf{z}_k = [z_{k,j}]_{j \in [n]}) \in \mathcal{Q}'_i(\tilde{s}_i)$ ,  $\mathcal{M}_1$  first generates  $\varepsilon_k \leftarrow \mathbb{Z}_{1+2\theta}^n = \{-\theta, \dots, \theta\}^n$ , and then computes

$$\begin{aligned} \mathbf{v}_k &\triangleq \mathbf{s} \cdot \mathbf{x}_k + q_0 \mathbf{w}_k + 2\varepsilon_k \\ &= \mathbf{s} \cdot (k\mathbf{c}_i + \mathbf{h}_k + 2\mathbf{e}_k) + q_0 \mathbf{w}_k + 2\varepsilon_k \\ &= k\Delta s_i \mathbf{c}_i + \left( k\tilde{s}_i \mathbf{c}_i + \sum_{r \in [i-1]} s_r h_{k,r} \mathbf{c}_r + q_0 \mathbf{w}_k \right) + 2(\mathbf{s}\mathbf{e}_k + \varepsilon_k) \\ &\sim \begin{bmatrix} \Delta s_i k\mathbf{c}_{i,1} + \left( k\tilde{s}_i \mathbf{c}_{i,1} + \sum_{r \in [i-1]} s_r h_{k,r} \mathbf{c}_{r,1} + q_0 w_{k,1} \right) \\ \vdots \\ \Delta s_i k\mathbf{c}_{i,n} + \left( k\tilde{s}_i \mathbf{c}_{i,n} + \sum_{r \in [i-1]} s_r h_{k,r} \mathbf{c}_{r,n} + q_0 w_{k,n} \right) \end{bmatrix} + \begin{bmatrix} 2(\varepsilon'_{k,1} + \varepsilon_{k,1}) \\ \vdots \\ 2(\varepsilon'_{k,n} + \varepsilon_{k,n}) \end{bmatrix} \\ &= \begin{bmatrix} \Delta s_i \cdot k\mathbf{c}_{i,1} + u_{k,1} + \text{Cha}(u_{k,1}) \cdot q_0 \\ \vdots \\ \Delta s_i \cdot k\mathbf{c}_{i,n} + u_{k,n} + \text{Cha}(u_{k,n}) \cdot q_0 \end{bmatrix} + \begin{bmatrix} 2(\varepsilon'_{k,1} + \varepsilon_{k,1}) \\ \vdots \\ 2(\varepsilon'_{k,n} + \varepsilon_{k,n}) \end{bmatrix}, \end{aligned}$$

where  $\varepsilon_{k,j} \triangleq \mu_j(\varepsilon_k)$  and  $\varepsilon'_{k,j} \triangleq \mu_j(\mathbf{s}e_k)$ . Finally, if every Parity  $(v_{k,j}) = z_{k,j}$  where  $v_{k,j} \triangleq \mu_j(\mathbf{v}_k)$ , then  $\mathcal{M}_1$  returns 1; Otherwise,  $\mathcal{M}_1$  returns 0.

Since  $q > 1 + 8 \cdot (\theta + n\alpha\alpha')$ , we have for every  $j \in [n]$  that

$$|\varepsilon'_{k,j} + \varepsilon_{k,j}| \leq |\varepsilon'_{k,j}| + |\varepsilon_{k,j}| \leq n\alpha\alpha' + \theta < \frac{q-1}{8}.$$

In such setting, similar to the proof of Lemma 7, it is not hard to verify that *except with negligible probability*,

- If  $\Delta s_i = 0$ , then  $\mathcal{M}_1$  returns 1 on every  $Q'_k \in \mathcal{Q}'_k(\tilde{s}_i)$  by Fact 6(b); And
- If  $\Delta s_i \neq 0$ , then  $\mathcal{M}_1$  returns 0 on some  $Q'_{k^*} \in \mathcal{Q}'_k(\tilde{s}_i)$  by Fact 6(c). □

The success of  $\mathcal{A}'_1$  is summarized in the following theorem. See Appendix B.1 for the pseudocode of  $\mathcal{A}'_1$ .

**Theorem 10.** *When  $q > 1 + 8(\theta + n\alpha\alpha')$ , the efficient algorithm  $\mathcal{A}'_1$  can recover the secret of  $\mathcal{M}_1$  w.o.p., by making at most  $n \cdot q \cdot \frac{q-1}{2n}$  queries to  $\mathcal{M}_1$ . Furthermore, in the  $i$ -th round, for every query  $(\mathbf{x}, \mathbf{w}, \mathbf{z})$  made by  $\mathcal{A}'_1$ , the  $\mathbf{x}$ -entry is always of the form  $\mathbf{x}_0 + 2\mathbf{e}$ , where  $\text{Dim}(\mathbf{x}_0) = [i]$  and  $\mathbf{e} \in \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ . □*

## 5.2 The “Undetectable” Attacker $(\mathcal{V}/\mathcal{A}'_1)_\delta$ Against $\mathcal{M}_1$

**Motivating question #2** We have defined an improved efficient attacker  $\mathcal{A}'_1$  against  $\mathcal{M}_1$ . To us, the most *practical* way for  $\mathcal{M}_1$  to identify those malicious queries made by  $\mathcal{A}'_1$  is to analyze the algebraic structure of the  $\mathbf{x}$ -entry. And the  $\mathbf{h}$ - and  $\mathbf{e}$ -parts were introduced to complicate the algebraic structure of  $\mathbf{x}$ . Clearly, the more CRT coefficients of  $\mathbf{s}$  we get, the more difficult for  $\mathcal{M}_1$  to distinguish those queries made by  $\mathcal{A}'_1$  from ordinary ones.

However, there is still a problem: when  $\mathcal{A}'_1$  seeks to recover the *first* CRT-coefficient of  $\mathbf{s}$  in its first round,  $\mathbf{h} = \mathbf{0}$  and hence the  $\mathbf{x}$ -entry falls into

$$\{k \cdot \mathbf{c}_i + 2\mathbf{e} \mid k \in \mathbb{F}_q, i \in [n], \mathbf{e} \in \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n\} \subseteq \mathcal{R}_q,$$

which is of “small” size compared with  $\mathcal{R}_q$ . It is not hard for  $\mathcal{M}_1$  to identify, and thus reject, these *first* set of queries, and it sounds “reasonable” for  $\mathcal{M}_1$  to reject an incoming query if its  $\mathbf{x}$ -entry falls into the foregoing set, given this set is of “small” size relative to  $\mathcal{R}_q$ . More broadly,  $\mathcal{M}_1$  can identify (and thus reject) an incoming query if its  $\mathbf{x}$ -entry can be written as  $\mathbf{x} = \mathbf{x}_0 + 2\mathbf{e}$  such that the CRT-dimension of  $\mathbf{x}_0$  is very “small” and  $\mathbf{e}$  is “short”. If such similar restrictions are imposed by  $\mathcal{M}_1$ ,  $\mathcal{A}'_1$  would fail since it cannot recover the first, and hence the remaining, CRT-coefficient of the secret  $\mathbf{s}$ .

Thus, our *second motivating question* arises: can we improve  $\mathcal{A}'_1$  so that it can still recover the secret of  $\mathcal{M}_1$ , even if the aforementioned requirement is imposed by  $\mathcal{M}_1$ ? The answer is affirmative, too, and we shall construct such a desired efficient attackers  $(\mathcal{V}/\mathcal{A}'_1)_\delta$  in this subsection.

**The hybrid attacker  $(\mathcal{V}/\mathcal{A}'_1)_\delta$**  Let  $\mathcal{P}_1$  denote the problem of recovering the secret of  $\mathcal{M}_1$ . Similarly, we can define a related problem  $\mathcal{P}_2$  as follows: given a nonempty index set  $I \subseteq [n]$ ,  $[\tilde{s}_i]_{i \in I} \in \mathbb{F}_q^{|I|}$ , and oracle access to  $\mathcal{M}_1$ , decide whether  $[s_i]_{i \in I} = [\tilde{s}_i]_{i \in I}$  or not, or more precisely, whether  $\tilde{s}_i = s_i$  for every  $i \in I$ . Recall that  $s_i = \eta_i(\mathbf{s})$ , where  $\mathbf{s}$  is the secret of  $\mathcal{M}_1$ . In this subsection, we shall construct an efficient solver  $\mathcal{V}$  against the problem  $\mathcal{P}_2$ . Jumping ahead, to solve the instance  $(I, [\tilde{s}_i]_{i \in I})$  of  $\mathcal{P}_2$ , for every query made by  $\mathcal{V}$  to  $\mathcal{M}_1$ , the  $\mathbf{x}$ -entry is always of the form  $\mathbf{x}_0 + 2\mathbf{e}$ , where  $\text{Dim}(\mathbf{x}_0) = I$  and  $\mathbf{e} \in \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ .

With the help of  $\mathcal{V}$ , we can construct a *hybrid* efficient attacker against  $\mathcal{M}_1$ , which consists of two *consecutive* phases as follows:

**Phase 1** First, choose a *constant*  $\delta$  of moderately large, and an index set  $I \subseteq [n]$  of size  $\delta$  *randomly*. Then, feed  $\mathcal{V}$  with  $q^\delta$  instances, each of the form  $(I, [\tilde{s}_i]_{i \in I})$ ,  $\tilde{s}_i \in \mathbb{F}_q$ . In this manner, the CRT-coefficients  $s_i, i \in I$ , would be recovered successfully when  $[\tilde{s}_i]_{i \in I}$  runs over the set  $\mathbb{F}_q^\delta$ .

In particular, the  $\mathbf{x}$ -entry of every query made in this phase is always of the form  $\mathbf{x}_0 + 2\mathbf{e}$ , where  $\text{Dim}(\mathbf{x}_0) = I$ , and  $\mathbf{e} \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ . Given the randomness of  $I$ , it is *almost impossible in practice* for  $\mathcal{M}_1$  to identify those queries made by  $\mathcal{V}$ .

**Phase 2** This phase consists of  $n - \delta$  rounds, each devoted to recovering one of the remaining  $n - \delta$  CRT-coefficients of  $\mathbf{s}$ , as is done in  $\mathcal{A}'_1$ .

In particular, the  $\mathbf{x}$ -entry of every query made in this phase is always of the form  $\mathbf{x}_0 + 2\mathbf{e}$  where  $\text{Dim}(\mathbf{x}_0) \supseteq I$  and  $\mathbf{e} \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ , making it *more difficult* for  $\mathcal{M}_1$  to identify them.

The notation  $(\mathcal{V}/\mathcal{A}'_1)_\delta$  is applied to emphasize the structure of this attacker.

Some remarks are in order. First, we stress that due to the randomness of the index set  $I$ , this makes it *almost impossible in practice* for  $\mathcal{M}_1$  to identify (and hence reject) those queries made by  $(\mathcal{V}/\mathcal{A}'_1)_\delta$ .

Moreover, notice that the algorithms  $\mathcal{A}'_1$  and  $\mathcal{V}$  are firmly related to each other: when  $\mathcal{M}_1$  imposes no restriction on the incoming queries,  $\mathcal{A}'_1$  could be adapted to solve the problem  $\mathcal{P}_2$  efficiently, and  $\mathcal{V}$  can be used to recover the *whole* secret  $s$  of  $\mathcal{M}_1$  efficiently as well.

Finally, notice that we could have used  $\mathcal{V}$  to recover the other CRT-coefficients of the secret in Phase 2. However, this is *less efficient*: it takes more queries *on average* for  $\mathcal{V}$  to recover one CRT-coefficient of  $s$  than  $\mathcal{A}'_1$  does, as we shall see.

**General structure of  $\mathcal{V}$**  We are about to design the desired  $\mathcal{V}$ . To simplify the following discussion, we only consider the *special* case where  $I = [n]$ , and it is easy to generalize to the more usual case where  $I$  is a *proper* subset of  $[n]$ .

First come some notations. Choose  $k \leftarrow [n]$  randomly. Let  $\Delta s_i \triangleq s_i - \tilde{s}_i$  for every  $i \in [n]$ . For every  $j \in [n]$ , define  $\mathbf{a}_j \triangleq [\tilde{s}_i \cdot c_{i,j}]_{i \in [n]} \in \mathbb{F}_q^n$ , and  $\mathbf{b}_j \triangleq [\Delta s_i \cdot c_{i,j}]_{i \in [n]} \in \mathbb{F}_q^n$ ; Moreover, define  $A_j(\mathbf{u}) \triangleq \langle \mathbf{u}, \mathbf{a}_j \rangle \in \mathbb{F}_q$ , and  $B_j(\mathbf{u}) \triangleq \langle \mathbf{u}, \mathbf{b}_j \rangle \in \mathbb{F}_q$ , where  $\mathbf{u} \in \mathbb{F}_q^n$ . Define the  $\mathbb{F}_q$ -vector space  $U_k \triangleq \{r \cdot \mathbf{a}_k \mid r \in \mathbb{F}_q\} \subseteq \mathbb{F}_q^n$ . By definition, every  $U_k$  is a 1-dimensional subspace of  $\mathbb{F}_q^n$ , and its orthogonal complement is the  $(n-1)$ -dimensional subspace  $U_k^\perp \triangleq \{\mathbf{v} \in \mathbb{F}_q^n \mid A_k(\mathbf{v}) = 0 \in \mathbb{F}_q\} \subseteq \mathbb{F}_q^n$ . Choose an  $\mathbb{F}_q$ -basis of  $U_k^\perp$  *randomly*, say  $\mathbf{F}_k \triangleq \{\mathbf{f}_{k,1}, \dots, \mathbf{f}_{k,n-1}\} \subseteq U_k^\perp$  such that every entry of every  $\mathbf{f}_{k,i}$  is non-zero. With  $U_k$ , the set  $\mathbb{F}_q^n$  is partitioned into three parts:  $S_1 \triangleq \mathbb{F}_q^n \setminus U_k$ ,  $S_2 \triangleq U_k \setminus \{\mathbf{0}\}$ , and  $S_3 \triangleq \{\mathbf{0}\}$ . Finally, for every  $(t, \mathbf{u}) \in \mathbb{F}_q \times \mathbb{F}_q^n$ , let  $\tau(t, \mathbf{u})$  denote  $\sum_{i \in [n]} t \mu_i(\mathbf{u}) \cdot \mathbf{c}_i \in \mathcal{R}_q$ .

Some remarks are in order. First, notice that for every  $i, j \in [n]$ ,  $s_i$ ,  $\Delta s_i$  and  $\mathbf{b}_j$  are unknown to us. Moreover, although the map  $A_j(\cdot)$  is efficiently computable, this is *not* true for  $B_j(\cdot)$ . Finally, recall that every  $c_{i,j} \neq 0$  by Proposition 5, so the guess  $[s_i]_{i \in [n]} = [\tilde{s}_i]_{i \in [n]}$  is correct if and only if  $\mathbf{b}_k = \mathbf{0} \in \mathbb{F}_q^n$ . Since  $\mathbf{0} \in S_3 \subseteq U_k$  trivially, a *necessary yet insufficient* condition for  $\mathbf{b}_k = \mathbf{0}$  is:  $\mathbf{b}_k \in U_k = S_2 \cup S_3$ , or equivalently,  $0 = \langle \mathbf{f}_{k,i}, \mathbf{b}_k \rangle = B_k(\mathbf{f}_{k,i})$  for every  $i \in [n-1]$ .

The general idea behind  $\mathcal{V}$  is simple: it first makes the guess, *i.e.*,  $[s_i]_{i \in [n]} = [\tilde{s}_i]_{i \in [n]}$ , and then verifies the correctness of the guess via a set  $\mathcal{Q} \triangleq \mathcal{Q}_1 \cup \mathcal{Q}_2$  of queries to  $\mathcal{M}_1$  such that *except with negligible probability*, the guess is correct if and only if  $\mathcal{M}_1$  returns 1 on *every* query in  $\mathcal{Q}$ .

In more detail,  $\mathcal{V}$  consists of two consecutive phases: Phase 1 and Phase 2.

- By issuing a set  $\mathcal{Q}_1$  of queries to  $\mathcal{M}_1$ , *Phase 1* is devoted to deciding whether  $\mathbf{b}_k \in U_k = S_2 \cup S_3$  or not;
- Conditioned on  $\mathbf{b}_k \in U_k$  and hence  $\mathbf{b}_k = r_0 \cdot \mathbf{a}_k$  for some  $r_0 \in \mathbb{F}_q$ , *Phase 2* is to decide whether  $r_0 = 0$  or not, by a set  $\mathcal{Q}_2$  of queries to  $\mathcal{M}_1$ .

It remains to design  $\mathcal{Q} = \mathcal{Q}_1 \cup \mathcal{Q}_2$ . Jumping ahead, for every query  $(\mathbf{x}, \mathbf{w}, \mathbf{z})$  in  $\mathcal{Q}$ , the  $\mathbf{x}$ -entry is always of the form  $\mathbf{x}_0 + 2\mathbf{e}$ , where  $\text{Dim}(\mathbf{x}_0) = I = [n]$ , and  $\mathbf{e} \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ . Similar to that of  $\mathcal{A}'_1$ , the  $\mathbf{e}$ -part is introduced here to make those queries made by  $\mathcal{V}$  as “random-looking” as possible.

**Design of Phase 1** Jumping ahead, the query set  $\mathcal{Q}_1 = \mathcal{Q}_1(\mathbf{F}_k)$  is

$$\mathcal{Q}_1(\mathbf{F}_k) \triangleq \left\{ Q_{t,i} = (\tau(t, \mathbf{f}_{k,i}) + 2\mathbf{e}_{t,i}, \mathbf{w}_{t,i}, \mathbf{z}_{t,i}) \mid t \in [q_0], i \in [n-1], \mathbf{e}_{t,i} \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n \right\}.$$

It remains to set the  $\mathbf{w}_{t,i}$ - and  $\mathbf{z}_{t,i}$ -entries.

Observe that for the query  $Q_{t,i} = (\tau(t, \mathbf{f}_{k,i}) + 2\mathbf{e}_{t,i}, \mathbf{w}_{t,i} = [w_{t,i,j}]_{j \in [n]}, \mathbf{z}_{t,i} = [z_{t,i,j}]_{j \in [n]}) \in \mathcal{Q}_1(\mathbf{F}_k)$ ,  $\mathcal{M}_1$  first generates  $\varepsilon_{t,i} \leftarrow \mathbb{Z}_{1+2\theta}^n$ , and then computes

$$\begin{aligned} \mathbf{v}_{t,i} &\triangleq \mathbf{s} \cdot (\tau(t, \mathbf{f}_{k,i}) + 2\mathbf{e}_{t,i}) + q_0 \cdot \mathbf{w}_{t,i} + 2\varepsilon_{t,i} \\ &= \mathbf{s} \cdot \tau(t, \mathbf{f}_{k,i}) + q_0 \cdot \mathbf{w}_{t,i} + 2(\varepsilon_{t,i} + \varepsilon'_{t,i}) \quad (\varepsilon'_{t,i} \triangleq \mathbf{s} \cdot \mathbf{e}_{t,i} \sim [\varepsilon'_{t,i,j}]_{j \in [n]}) \\ &\sim \begin{bmatrix} t \cdot A_1(\mathbf{f}_{k,i}) + t \cdot B_1(\mathbf{f}_{k,i}) + q_0 \cdot w_{t,i,1} \\ \vdots \\ t \cdot A_k(\mathbf{f}_{k,i}) + t \cdot B_k(\mathbf{f}_{k,i}) + q_0 \cdot w_{t,i,k} \\ \vdots \\ t \cdot A_n(\mathbf{f}_{k,i}) + t \cdot B_n(\mathbf{f}_{k,i}) + q_0 \cdot w_{t,i,n} \end{bmatrix} + \begin{bmatrix} 2(\varepsilon_{t,i,1} + \varepsilon'_{t,i,1}) \\ \vdots \\ 2(\varepsilon_{t,i,k} + \varepsilon'_{t,i,k}) \\ \vdots \\ 2(\varepsilon_{t,i,n} + \varepsilon'_{t,i,n}) \end{bmatrix}. \end{aligned}$$

Notice that when  $q > 1 + 8(\theta + n\alpha')$ , the noise  $(\varepsilon_{t,i} + \varepsilon'_{t,i})$  is “short” in the sense that  $\|\varepsilon_{t,i} + \varepsilon'_{t,i}\|_\infty < \frac{q-1}{8}$  holds *w.o.p.*

And this definition is justified by the following lemma.

**Lemma 11.** *Define*

$$\mathcal{Q}_1(\mathbf{F}_k) \triangleq \left\{ Q_{t,i} = (\tau(t, \mathbf{f}_{k,i}) + 2\mathbf{e}_{t,i}, [w_{t,i,j}]_{j \in [n]}, [z_{t,i,j}]_{j \in [n]}) \mid \begin{array}{l} t \in [q_0], i \in [n-1], j \in [n], \mathbf{e}_{t,i} \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n, \\ u_{t,i,j} = tA_j(\mathbf{f}_{k,i}), w_{t,i,j} = \text{Cha}(u_{t,i,j}), \\ z_{t,i,j} = \text{Mod}(u_{t,i,j}, w_{t,i,j}) \end{array} \right\}.$$

When  $q > 1 + 8(\theta + n\alpha\alpha')$ , except with negligible probability, we have

- (a) If  $\mathcal{M}_1$  returns 0 on some queries in  $\mathcal{Q}_1(\mathbf{F}_k)$ , then  $\mathbf{b}_k \neq \mathbf{0}$  and hence  $[s_i]_{i \in [n]} \neq [\tilde{s}_i]_{i \in [n]}$ ;
- (b) If  $\mathcal{M}_1$  returns 1 on every query in  $\mathcal{Q}_1(\mathbf{F}_k)$ , then  $\mathbf{b}_k \in U_k = S_2 \cup S_3$ .

*Proof.* First, if  $\mathbf{b}_k \in S_3 = \{\mathbf{0}\}$ , then our guess is correct, every  $\mathbf{b}_j = \mathbf{0}$  and hence every  $B_j(\cdot) = 0$ ; By Fact 6(b),  $\mathcal{M}_1$  returns 1 w.o.p. for every query in  $\mathcal{Q}_1(\mathbf{F}_k)$ .

Moreover, if  $\mathbf{b}_k \in S_1 = \mathbb{F}_q^n \setminus U_k$ , then there exists  $\mathbf{f}_{k,i^*} \in \mathbf{F}_k$  such that  $B_k(\mathbf{f}_{k,i^*}) \neq 0$ ; Moreover, there exists a  $t^* \in [q_0]$  such that  $t^* \cdot B_k(\mathbf{f}_{k,i^*}) = \pm 1$ . By Fact 6(c),  $\mathcal{M}_1$  returns 0 w.o.p. for at least one query in  $\mathcal{Q}_1(\mathbf{F}_k)$ .  $\square$

It should be noted that, in Phase 1, it is *difficult* to analyze the distribution of query replies when  $\mathbf{b}_k \in S_2$ , which explains the necessity of Phase 2.

**Design of Phase 2** In Phase 2, conditioned on the hypothesis  $\mathbf{b}_k \in U_k = S_2 \cup S_3$ , it remains to consider whether  $\mathbf{b}_k \in S_2$  or  $\mathbf{b}_k \in S_3 = \{\mathbf{0}\}$ . By hypothesis, we have  $\mathbf{b}_k \in U_k = \{r \cdot \mathbf{a}_k \mid r \in \mathbb{F}_q\}$ ; Hence, we can assume  $\mathbf{b}_k = r_0 \cdot \mathbf{a}_k$  for some  $r_0 \in \mathbb{F}_q$ . Then  $B_k(\mathbf{u}) = r_0 \cdot A_k(\mathbf{u})$  for every  $\mathbf{u} \in \mathbb{F}_q^n$ . Moreover, our guess now could be expressed in terms of  $r_0$ , i.e., whether  $r_0 = 0$  or not.

Choose  $\mathbf{u}^* \leftarrow \mathcal{R}_q$  randomly such that  $A_k(\mathbf{u}^*) = 1$  and every entry of  $\mathbf{u}^*$  is non-zero. It follows  $t \cdot A_k(\mathbf{u}^*) + t \cdot B_k(\mathbf{u}^*) = t(1 + r_0)$  for every  $t \in \mathbb{F}_q$ . Jumping ahead, the set  $\mathcal{Q}_2 = \mathcal{Q}_2(\mathbf{u}^*)$  is

$$\mathcal{Q}_2(\mathbf{u}^*) \triangleq \{Q'_t = (\tau(t, \mathbf{u}^*) + 2\mathbf{e}_t, \mathbf{w}_t, \mathbf{z}_t) \mid t \in [q_0], \mathbf{e}_t \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n\}.$$

It remains to set the  $\mathbf{w}_t$ - and  $\mathbf{z}_t$ -entries.

Observe that for every query  $Q'_t = (\tau(t, \mathbf{u}^*) + 2\mathbf{e}_t, \mathbf{w}_t = [w_{t,j}]_{j \in [n]}, \mathbf{z}_t = [z_{t,j}]_{j \in [n]})$ ,  $\mathcal{M}_1$  first generates  $\varepsilon_t \leftarrow \mathbb{Z}_{1+2\theta}^n$ , and then computes

$$\begin{aligned} \mathbf{v}'_t &\triangleq \mathbf{s} \cdot (\tau(t, \mathbf{u}^*) + 2\mathbf{e}_t) + q_0 \cdot \mathbf{w}_t + 2\varepsilon_t \\ &= \mathbf{s} \cdot \tau(t, \mathbf{u}^*) + q_0 \cdot \mathbf{w}_t + 2(\varepsilon_t + \varepsilon'_t) \quad (\varepsilon'_t \triangleq \mathbf{s} \cdot \mathbf{e}_t \sim [\varepsilon'_{t,j}]_{j \in [n]}) \\ &\sim \begin{bmatrix} t \cdot A_1(\mathbf{u}^*) + t \cdot B_1(\mathbf{u}^*) + q_0 w_{t,1} \\ \vdots \\ t + t \cdot r_0 + q_0 w_{t,k} \\ \vdots \\ t \cdot A_n(\mathbf{u}^*) + t \cdot B_n(\mathbf{u}^*) + q_0 w_{t,n} \end{bmatrix} + \begin{bmatrix} 2(\varepsilon_{t,1} + \varepsilon'_{t,1}) \\ \vdots \\ 2(\varepsilon_{t,k} + \varepsilon'_{t,k}) \\ \vdots \\ 2(\varepsilon_{t,n} + \varepsilon'_{t,n}) \end{bmatrix}. \end{aligned}$$

Again, when  $q > 1 + 8(\theta + n\alpha\alpha')$ , the inequality  $\|\varepsilon_t + \varepsilon'_t\|_\infty < \frac{q-1}{8}$  holds w.o.p. With this in mind, we can define

$$\mathcal{Q}_2(\mathbf{u}^*) \triangleq \left\{ Q'_t = (\tau(t, \mathbf{u}^*) + 2\mathbf{e}_t, [w_{t,j}]_{j \in [n]}, [z_{t,j}]_{j \in [n]}) \mid \begin{array}{l} t \in [q_0], j \in [n], \mathbf{e}_t \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n, u_{t,j} = tA_j(\mathbf{u}^*), \\ w_{t,j} = \text{Cha}(u_{t,j}), z_{t,j} = \text{Mod}(u_{t,j}, w_{t,j}) \end{array} \right\}.$$

And the definition is justified by the following lemma.

**Lemma 12.** *With the notations defined previously, if  $q > 1 + 8(\theta + n\alpha\alpha')$  and  $\mathbf{b}_k \in U_k$  are guaranteed, then except with negligible probability, we have  $[s_i]_{i \in [n]} = [\tilde{s}_i]_{i \in [n]}$  if and only if  $\mathcal{M}_1$  returns 1 on every query in  $\mathcal{Q}_2(\mathbf{u}^*)$ .*

*Proof.* First, if  $[s_i]_{i \in [n]} = [\tilde{s}_i]_{i \in [n]}$ , then our guess is correct,  $r_0 = 0$ , and every  $B_j(\cdot) = 0$ . By Fact 6(b),  $\mathcal{M}_1$  returns 1 on every query in  $\mathcal{Q}_2(\mathbf{u}^*)$ .

Conversely, if  $r_0 \neq 0$ , then there exists a  $t^* \in [q_0]$  such that  $t^* r_0 = \pm 1$ . By Fact 6(c), for the specific query  $Q'_{t^*} = (\tau(t^*, \mathbf{u}^*) + 2\mathbf{e}_{t^*}, \mathbf{w}_{t^*}, \mathbf{z}_{t^*}) \in \mathcal{Q}_2(\mathbf{u}^*)$ , its associated  $k$ -th equality does not hold w.o.p. By definition,  $\mathcal{M}_1$  returns 0 w.o.p. on this specific query  $Q'_{t^*} \in \mathcal{Q}_2(\mathbf{u}^*)$ .  $\square$

This finishes the construction of  $\mathcal{V}$ , as well as its correctness analysis, for the *special* case when the index set  $I = [n]$ . Clearly it takes at most  $n \cdot q_0 = \text{poly}(\lambda)$  queries for  $\mathcal{V}$  to solve this *special* case of  $\mathcal{P}_2$ , indicating that  $\mathcal{V}$  runs in polynomial time. See Appendix B.2 for the pseudocode of  $\mathcal{V}$ .

Moreover, it is easy to generalize the foregoing construction such that  $\mathcal{V}$  could be applied to solve the more general case of  $\mathcal{P}_2$ , i.e.,  $\emptyset \neq I \subsetneq [n]$ . In general, the number of queries made by  $\mathcal{V}$  is upper-bounded by  $q_0 \cdot |I| = q_0 \delta = \text{poly}(\lambda)$ .

**Theorem 13.** *Assume  $q > 1 + 8(\theta + n\alpha\alpha')$ . With the notations defined previously, given  $\emptyset \neq I \subseteq [n]$ ,  $[\tilde{s}_i]_{i \in I}$  and oracle access to  $\mathcal{M}_1$ , it takes at most  $q_0 \cdot |I| = q_0 \cdot \delta$  queries for  $\mathcal{V}$  to decide whether  $[s_i]_{i \in [n]} = [\tilde{s}_i]_{i \in [n]}$  or not: except with negligible probability, the equality holds if and only if  $\mathcal{M}_1$  returns 1 on every query in  $\mathcal{Q} = \mathcal{Q}_1 \cup \mathcal{Q}_2$ . In particular, for every query in  $\mathcal{Q}$ , its  $\mathbf{x}$ -entry could be written as  $\mathbf{x} = \mathbf{x}_0 + 2\mathbf{e}$  satisfying  $\text{Dim}(\mathbf{x}_0) = I$  and  $\mathbf{e} \in \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ .  $\square$*

**Theorem 14.** *When  $q > 1 + 8(\theta + n\alpha\alpha')$ , there exists an efficient attacker  $(\mathcal{V}/\mathcal{A}'_1)_\delta$  that can recover the secret of  $\mathcal{M}_1$  w.o.p., after making  $q_0\delta \cdot q^\delta + (n - \delta) \cdot q \cdot \frac{q-1}{2n} = \text{poly}(\lambda)$  queries to  $\mathcal{M}_1$ . In particular, for every query made by  $(\mathcal{V}/\mathcal{A}'_1)_\delta$  to  $\mathcal{M}_1$ , its  $\mathbf{x}$ -entry is always of the form  $\mathbf{x} = \mathbf{x}_0 + 2\mathbf{e}$  where  $|\text{Dim}(\mathbf{x}_0)| \geq \delta$  and  $\mathbf{e} \in \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ .  $\square$*

**Remarks** To us, the best way for  $\mathcal{M}_1$  to decide whether an incoming query is made by our small field attacker or not is to check the algebraic structure of its  $\mathbf{x}$ -entry, i.e., whether  $\mathbf{x}$  can be written in the form  $\mathbf{x}_0 + 2\mathbf{e}$  such that  $\text{Dim}(\mathbf{x}_0)$  is “small” and  $\mathbf{e}$  is “short”. Such check is similar to the bounded distance decoding problem, and it seems to us that the best way to do such check is close to the brute-force. In practice, the instantiation of  $\mathcal{M}_1$  should decide whether an incoming query is malicious or not in a *timely* manner; Moreover, such restriction imposed by  $\mathcal{M}_1$  should be *reasonable* in the sense that the *false negative rate* (i.e., the probability that an “innocent” query made by an “honest” caller is considered a malicious one made by our small field attackers) cannot be too high. To identify those queries made by  $(\mathcal{V}/\mathcal{A}'_1)_\delta$ , the best way is to identify those queries made by  $(\mathcal{V}/\mathcal{A}'_1)_\delta$  in its Phase 1. Hence, when  $\delta$  is moderately large, given the randomness of  $I$ , it takes too much time in practice to do so, and the false negative rate is intuitively high. In sum, it is *too costly to be practical* for  $\mathcal{M}_1$  to protect its secret  $\mathbf{s}$  from our efficient attacker  $(\mathcal{V}/\mathcal{A}'_1)_\delta$ , even if the foregoing restrictions are imposed by  $\mathcal{M}_1$  on incoming queries.

## 6 The Small Field Attack Against $\Pi_1$

In this section, we are devoted to the construction of the efficient attacker  $\mathcal{A}_0$  which can recover the private key of  $\mathcal{M}_0$  (defined in Section 4.2), after a set of queries made to  $\mathcal{M}_0$ ; Moreover, both the public key of  $\mathcal{A}_0$  and those queries it makes to  $\mathcal{M}_0$  are as “random-looking” as possible. The existence of  $\mathcal{A}_0$  implies  $\Pi_1$  is vulnerable to our small field attack.

**Construction of  $\mathcal{A}_0$**  The oracle  $\mathcal{M}_1$  is a simplified variant of  $\mathcal{M}_0$ . And it is natural that the desired  $\mathcal{A}_0$  is very close to the hybrid attacker  $(\mathcal{V}/\mathcal{A}'_1)_\delta$  against  $\mathcal{M}_1$ . Given that the public key  $\mathbf{p} = \mathbf{a}\mathbf{s} + 2\mathbf{e} \in \mathcal{R}_q$  of  $\mathcal{M}_0$  is made public, to recover the private key  $(\mathbf{s}, \mathbf{e})$  of  $\mathcal{M}_0$ , it suffices for  $\mathcal{A}_0$  to recover  $\mathbf{s} \in \mathcal{R}_q$ . Moreover, it suffices for  $\mathcal{A}_0$  to recover every CRT-coefficient  $s_i \triangleq \eta_i(\mathbf{s})$ ,  $1 \leq i \leq n$ , of  $\mathbf{s}$ .

$\mathcal{A}_0$  consists of three *consecutive* phases: *Phase 0*, *Phase 1*, and *Phase 2*. In Phase 0,  $\mathcal{A}_0$  generates its public/private key pair as follows: first, it chooses a positive integer  $\delta$  that is moderately large, say  $\delta$ ; Then, it chooses a proper index set  $I \subseteq [n]$  of size  $\delta$  *uniformly at random*; After that, it samples  $\mathbf{p}_0^* \leftarrow \{\mathbf{u} \in \mathcal{R}_q \mid \text{Dim}(\mathbf{u}) = I\}$  and  $\mathbf{e}_0^* \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$  uniformly at random; The public key of  $\mathcal{A}_0$  is  $\mathbf{p}^* \triangleq \mathbf{p}_0^* + 2\mathbf{e}_0^*$ , and the associated private key of  $\mathcal{A}_0$  is  $(\mathbf{s}^*, \mathbf{e}^*)$ , where  $\mathbf{s}^* \leftarrow \mathcal{R}_q$  is drawn randomly and  $\mathbf{e}^* \triangleq 2^{-1}(\mathbf{p}^* - \mathbf{a}\mathbf{s}^*)$ . It should be stressed that the public/private key pair of  $\mathcal{A}_0$  is *not* honestly generated.

The Phase 1 and Phase 2 of  $\mathcal{A}_0$  are devoted to the recovery of every  $s_i = \eta_i(\mathbf{s})$ ,  $i \in [n]$ , and their functionalities are similar to those of  $(\mathcal{V}/\mathcal{A}'_1)_\delta$ , respectively: Phase 1 is devoted to recovering  $\delta$  CRT-coefficients of  $\mathbf{s}$ , i.e.,  $\{s_i \mid i \in I\}$  where  $I \subseteq [n]$  is of size  $\delta$ , and Phase 2 is to recover the others ones.

For simplicity, only the Phase 2 of  $\mathcal{A}_0$  is fully described here. For the moment, we assume that  $I \subseteq [i - 1]$  and the CRT-coefficients  $s_1, \dots, s_{i-1} \in \mathbb{F}_q$  have already been recovered successfully, and we are about to see how  $\mathcal{A}_0$  recovers a *new* CRT-coefficient of  $\mathbf{s}$ , say  $s_i \in \mathbb{F}_q$ , via a set of queries to  $\mathcal{M}_0$ . The general strategy is simple: first, pick  $\tilde{s}_i \leftarrow \mathbb{F}_q$  randomly, and guess  $s_i = \tilde{s}_i$ ; Then, conduct a set  $\mathcal{Q}_i(\tilde{s}_i)$  of queries to  $\mathcal{M}_0$  such that *except with negligible probability*,  $s_i = \tilde{s}_i$  if and only if  $\mathcal{M}_0$  returns 1 on every query in  $\mathcal{Q}_i(\tilde{s}_i)$ ; When  $\tilde{s}_i$  runs over the set  $\mathbb{F}_q$ , the exact value of  $s_i$  would be recovered *w.o.p.*

Jumping ahead, every query in  $\mathcal{Q}_i(\tilde{s}_i)$  is of the form  $(\text{id}^*, \mathbf{p}^*, \mathbf{x}_k = k\mathbf{c}_i + \mathbf{h}_k + 2\mathbf{e}_k, \mathbf{w}_k, \mathbf{z}_k)$ , where  $k \in [q_0]$ ,  $\mathbf{h}_k \leftarrow \{\mathbf{u} \in \mathcal{R}_q \mid \text{Dim}(\mathbf{u}) = [i-1]\}$ ,  $\mathbf{e}_k \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}$ , and  $\mathbf{w}_k, \mathbf{z}_k \in \mathbb{B}^n$  are to be determined later.

Recall that, on the query  $(\text{id}, \mathbf{p}, \mathbf{x}_k = k\mathbf{c}_i + \mathbf{h}_k + 2\mathbf{e}_k, \mathbf{w}_k, \mathbf{z}_k)$  where  $\mathbf{h}_k = \sum_{r \in [i-1]} h_{k,r} \mathbf{c}_r$ ,  $h_{k,r} \leftarrow \mathbb{F}_q^\times$ , the oracle  $\mathcal{M}_0$  first samples  $\mathbf{g} \leftarrow D_{\mathbb{Z}^n, \alpha}$ , then compute  $\mathbf{c} \triangleq H_1(\text{id}, \text{id}^*, \mathbf{x}_k)$  and

$$\begin{aligned} \mathbf{v}_k &\triangleq (\mathbf{p}^* \mathbf{c} + \mathbf{x}_k) \mathbf{s} + q_0 \cdot \mathbf{w}_k + 2\mathbf{c} \cdot \mathbf{g} \\ &= k \cdot \mathbf{s} \cdot \mathbf{c}_i + \mathbf{p}_0^* \mathbf{c} \mathbf{s} + \mathbf{s} \cdot \mathbf{h}_k + q_0 \cdot \mathbf{w}_k + 2 \cdot (\mathbf{e}_k \mathbf{s} + \mathbf{e}_0^* \mathbf{c} \mathbf{s} + \mathbf{c} \mathbf{g}) \\ &= k \Delta s_i \mathbf{c}_i + (k \tilde{s}_i \mathbf{c}_i + \mathbf{p}_0^* \mathbf{c} \mathbf{s} + \mathbf{s} \cdot \mathbf{h}_k + q_0 \cdot \mathbf{w}_k) + 2\mathbf{e}_k \quad (\mathbf{e}_k \triangleq \mathbf{e}_k \mathbf{s} + \mathbf{e}_0^* \mathbf{c} \mathbf{s} + \mathbf{c} \mathbf{g} \sim [\varepsilon_{k,j}]_{j \in [n]}) \\ &= \begin{bmatrix} \Delta s_i \cdot k c_{i,1} + \left( k \tilde{s}_i c_{i,1} + \sum_{r \in I} \eta_r (\mathbf{p}_0^* \mathbf{c} \mathbf{s})_{c_{r,1}} + \sum_{r \in [i-1]} s_r h_{k,r} c_{r,1} + q_0 w_{k,1} \right) \\ \vdots \\ \Delta s_i \cdot k c_{i,n} + \left( k \tilde{s}_i c_{i,n} + \sum_{r \in I} \eta_r (\mathbf{p}_0^* \mathbf{c} \mathbf{s})_{c_{r,n}} + \sum_{r \in [i-1]} s_r h_{k,r} c_{r,n} + q_0 w_{k,n} \right) \end{bmatrix} + 2 \cdot \begin{bmatrix} \varepsilon_{k,1} \\ \vdots \\ \varepsilon_{k,n} \end{bmatrix}, \end{aligned}$$

where  $\Delta s_i \triangleq s_i - \tilde{s}_i$ ; Finally,  $\mathcal{M}_0$  computes  $\sigma_k := \text{Parity}(\mathbf{v}_k)$ , and returns 1 if and only if  $\sigma_k = \mathbf{z}_k$ . Notice that  $\text{Dim}(\mathbf{p}_0^* \mathbf{c} \mathbf{s}) \subseteq \text{Dim}(\mathbf{p}_0^*) = I$ , making it possible for  $\mathcal{A}_0$  to pre-compute every  $\eta_r(\mathbf{p}_0^* \mathbf{c} \mathbf{s})$ ,  $r \in I$ , before issuing the query.

It is not hard to verify the correctness of the following lemma.

**Lemma 15.** *Let  $g$  denote a primitive element of  $\mathbb{F}_q^\times$ , and define  $d \triangleq \frac{q-1}{m}$ ,  $S_g \triangleq \{g^r \mid r \in [d]\}$ . With the notations defined previously, if  $I \subseteq [i-1]$  and  $s_1, \dots, s_{i-1}$  have been given and  $q > 1 + 8(n\alpha\alpha' + n\alpha\gamma + n^2\alpha^2\gamma)$ , then except with negligible probability,  $\Delta s_i = 0$  if and only if  $\mathcal{M}_0$  returns 1 on every query in*

$$\mathcal{Q}_i(\tilde{s}_i) = \left\{ \left( \text{id}^*, \mathbf{p}^*, k\mathbf{c}_i + \mathbf{h}_k + 2\mathbf{e}_k, [w_{k,j}]_{j \in [n]}, [z_{k,j}]_{j \in [n]} \right) \left| \begin{array}{l} k \in S_g, j \in [n], h_{k,1}, \dots, h_{k,i-1} \leftarrow \mathbb{F}_q^\times, \\ \mathbf{h}_k = \sum_{r \in [i-1]} h_{k,r} \mathbf{c}_r, \mathbf{e}_k \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n, \\ u_{k,j} = k \tilde{s}_i c_{i,j} + \sum_{r \in I} \eta_r (\mathbf{p}_0^* \mathbf{c} \mathbf{s})_{c_{r,j}} + \sum_{r \in [i-1]} s_r h_{k,r} c_{r,j}, \\ w_{k,j} = \text{Cha}(u_{k,j}), z_{k,j} = \text{Mod}(u_{k,j}, w_{k,j}) \end{array} \right. \right\}.$$

In particular, for every query in  $\mathcal{Q}_i(\tilde{s}_i)$ , its  $\mathbf{x}$ -entry is always of the form  $\mathbf{x}_0 + 2\mathbf{e}$ , where  $\text{Dim}(\mathbf{x}_0) = [i]$  and  $\mathbf{e} \in \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ .  $\square$

The correctness and the efficiency of  $\mathcal{A}_0$  can be easily verified. In sum, the efficient attacker  $\mathcal{A}_0$  implies the existence of the desired efficient attacker against the honest party  $j$  in  $\Pi_1$ , as the following theorem indicates.

**Theorem 16.** *With the notations defined previously, when  $q > 1 + 8(n\alpha\alpha' + n\alpha\gamma + n^2\alpha^2\gamma)$ , there exists an efficient adversary  $\mathcal{A}$  that can recover the static private key of the honest party  $j$  in  $\Pi_1$  w.o.p. In particular, for every query made by  $\mathcal{A}$ , its  $\mathbf{x}$ -entry is always of the form  $\mathbf{x}_0 + 2\mathbf{e}$ , where  $|\text{Dim}(\mathbf{x}_0)| \geq \delta$  and  $\mathbf{e} \in \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ .  $\square$*

**Experimental results** In [ZZDS14,ZZD<sup>+</sup>15], four groups of suggested parameters for  $\Pi_1$  are proposed; Also,  $\gamma := \alpha$  is suggested. We should stress that all of these four groups of parameters satisfy the parameter requirement in Theorem 16. And, computer experiments have justified the correctness of our analysis.

**Remarks** By the ring-LWE assumption, the distribution of the static public key of an *honest* player is computationally indistinguishable from the uniform distribution over  $\mathcal{R}_q$ . Therefore, from the viewpoint of the honest party  $j$ , every element in  $\mathcal{R}_q$  is *equally* likely to be the static public key of an honest initiator.

Similar to  $(\mathcal{V}/\mathcal{A}'_1)_\delta$ , the efficient adversary  $\mathcal{A}$  against  $\Pi_1$  can make its session queries to the honest party  $j$  as random-looking as possible by choosing an appropriate  $\delta$ , making it *almost impossible in practice* for party  $j$  to identify (and hence reject) those session queries made by  $\mathcal{A}$ .

## 7 Analysis on the Two-pass AKE Protocol $\Pi_2$

In  $\Pi_2$ , the static private key of party  $i$  is  $(\mathbf{s}_i \leftarrow D_{\mathbb{Z}^n, \alpha}, \mathbf{e}_i \leftarrow D_{\mathbb{Z}^n, \alpha})$ , and the associate static public key is  $\mathbf{p}_i \triangleq \mathbf{a} \mathbf{s}_i + 2\mathbf{e}_i \in \mathcal{R}_q$ , where  $\mathbf{a} \in \mathcal{R}_q$  denotes a global parameter of  $\Pi_2$  that is drawn from the uniform distribution over  $\mathcal{R}_q$ . Similar notations,  $(\mathbf{s}_j, \mathbf{e}_j), \mathbf{p}_j$ , carry over to party  $j$  in  $\Pi_2$ .

Here is a brief review of the two-pass AKE scheme  $\Pi_2$  proposed in [ZZDS14,ZZD<sup>+</sup>15].

**Initiation** First, party  $i$  acts as follows:

1. Pick  $r_i, f_i \leftarrow D_{\mathbb{Z}^n, \beta}$ , and compute  $x_i \triangleq ar_i + 2f_i$ .
2. Compute  $c \triangleq H_1(\text{id}_i, \text{id}_j, x_i)$ ,  $\hat{r}_i \triangleq s_i c + r_i$  and  $\hat{f}_i \triangleq e_i c + f_i$ .
3. Let  $z \in \mathbb{Z}^{2n}$  be the coefficient vector of  $\hat{r}_i$  concatenated with that of  $\hat{f}_i$ , and  $z_1$  be the coefficient vector of  $s_i c$  concatenated with that of  $e_i c$ . Repeat steps 1-3 with probability  $1 - \min\left(1, \frac{D_{\mathbb{Z}^{2n}, \beta}(z)}{M \cdot D_{\mathbb{Z}^{2n}, \beta, z_1}(z)}\right)$ .
4. Send  $x_i$  to party  $j$ .

**Response** On message  $x_i$ , party  $j$  works as follows:

1. Pick  $r_j, f_j \leftarrow D_{\mathbb{Z}^n, \beta}$ , and compute  $y_j \triangleq ar_j + 2f_j$ .
2. Compute  $d \triangleq H_1(\text{id}_i, \text{id}_j, y_j, x_i)$ ,  $\hat{r}_j \triangleq s_j d + r_j$  and  $\hat{f}_j \triangleq e_j d + f_j$ .
3. Let  $z \in \mathbb{Z}^{2n}$  be the coefficient vector of  $\hat{r}_j$  concatenated with that of  $\hat{f}_j$ , and  $z_1$  be the coefficient vector of  $s_j d$  concatenated with that of  $e_j d$ . Repeat steps 1-3 with probability  $1 - \min\left(1, \frac{D_{\mathbb{Z}^{2n}, \beta}(z)}{M \cdot D_{\mathbb{Z}^{2n}, \beta, z_1}(z)}\right)$ .
4. Pick  $g_j \leftarrow D_{\mathbb{Z}^n, \beta}$ , and compute  $k_j \triangleq (p_i c + x_i) \cdot \hat{r}_j + 2c g_j$ .
5. Let  $w_j \triangleq \text{Cha}(k_j) \in \mathbb{B}^n$ , and send  $(y_j, w_j)$  to party  $i$ .
6. Compute  $\sigma_j \triangleq \text{Mod}(k_j, w_j)$ , and derive the session key  $\text{sk}_j \triangleq H_2(\text{id}_i, \text{id}_j, x_i, y_j, w_j, \sigma_j)$ .

**Finish** On message  $(y_j, w_j)$ , party  $i$  proceeds as follows:

1. Pick  $g_i \leftarrow D_{\mathbb{Z}^n, \beta}$ , and compute  $k_i \triangleq (p_j d + y_j) \cdot \hat{r}_i + 2d g_i$ .
2. Compute  $\sigma_i \triangleq \text{Mod}(k_i, w_j)$ , and derive the session key  $\text{sk}_i \triangleq H_2(\text{id}_i, \text{id}_j, x_i, y_j, w_j, \sigma_i)$ .

## 7.1 Claim 16, and the Underlying Games $G_{2,4}, G_{2,5}$

In the security proof of  $\Pi_2$  [ZZDS14], the set of PPT adversaries is partitioned into *five* types, according to the internal structures of the test session. We are interested in the Type-II adversaries w.r.t. the test session denoted  $(\Pi_2, I, \text{id}_{i^*}, \text{id}_{j^*}, x_{i^*}, (y_{j^*}, w_{j^*}))$ , in which the adversary  $\mathcal{A}$  impersonates the honest user  $j^*$  but  $y_{j^*}$  is *not* sent by  $j^*$  upon receiving  $x_{i^*}$  from  $i^*$ ; In other words, the test session has no matching session in this case. Claim 16, together with other claims, is devoted to establishing the provable security regarding Type-II adversary, and two games are involved in Claim 16:  $G_{2,4}$  and  $G_{2,5}$ . Roughly speaking, the difference between  $G_{2,4}$  and  $G_{2,5}$  lies in the simulation of the test-session, as summarized below. Please refer to [ZZDS14] for the full detail.

Denote by  $\text{sid}^* \triangleq (\Pi_2, I, \text{id}_{i^*}, \text{id}_{j^*}, x_{i^*}, (y_{j^*}, w_{j^*}))$  the test session, where  $x_{i^*}$  is output by honest party  $i^*$  with intended honest party  $j^*$ . In  $G_{2,4}$ , the simulator  $\mathcal{S}$  maintains two tables  $L_1, L_2$  for the random oracles  $H_1(\cdot), H_2(\cdot)$ , respectively. Now,  $\mathcal{S}$  chooses  $u_0, u_1 \leftarrow \mathcal{R}_q$ , and sets the global parameter  $\mathbf{a}$  to be  $u_0$ , and sets the static public key of party  $j^*$  to be  $u_1$ , i.e.,  $\mathbf{a} := u_0, \mathbf{p}_{j^*} := u_1$ . Moreover,  $\mathcal{S}$  prepares the table

$$T \triangleq \left\{ \left( \hat{r}_k, \hat{f}_k, g_k, v_{0,k}, v_{1,k} \right) \mid \begin{array}{l} 1 \leq k \leq \ell, \hat{r}_k, \hat{f}_k, g_k \leftarrow D_{\mathbb{Z}^n, \beta}, \\ v_{0,k} = u_0 \hat{r}_k + 2\hat{f}_k, \\ v_{1,k} = u_1 \hat{r}_k + 2g_k \end{array} \right\}.$$

Finally, for the test session,  $\mathcal{S}$  answers oracle queries made by the efficient adversary  $\mathcal{A}$  as follows:

- Upon receiving  $\text{Send}_0(\Pi_2, I, \text{id}_{i^*}, \text{id}_{j^*})$  w.r.t. the test session,  $\mathcal{S}$  proceeds as follow:
  1. Sample an invertible element  $c^* \leftarrow D_{\mathbb{Z}^n, \gamma}$ , and choose the *first unused* tuple in  $T$ , say the  $\ell^*$ -th tuple, and set  $\hat{x}_{i^*} := v_{0, \ell^*}$ .
  2. Define  $x_{i^*} := \hat{x}_{i^*} - p_{i^*} c^*$ .
  3. Repeat steps 1-2 with probability  $1 - 1/M$ , where  $M$  is a sufficiently large positive integer.
  4. Abort if there is a tuple  $((\text{id}_{i^*}, \text{id}_{j^*}, x_{i^*}), *) \in L_1$ . Else, add  $((\text{id}_{i^*}, \text{id}_{j^*}, x_{i^*}), c^*)$  into  $L_1$ , and return  $x_{i^*}$  to the adversary  $\mathcal{A}$ .
- Upon receiving  $\text{Send}_2(\Pi_2, I, \text{id}_{i^*}, \text{id}_{j^*}, x_{i^*}, (y_{j^*}, w_{j^*}))$  w.r.t. the test-session,  $\mathcal{S}$  proceeds as follow:
  5. Set  $d^* \leftarrow H_1(\text{id}_{j^*}, \text{id}_{i^*}, y_{j^*}, x_{i^*})$ , and compute

$$k_{i^*} := d^* v_{1, \ell^*} + y_{j^*} \hat{r}_{\ell^*} = (p_{j^*} d^* + y_{j^*}) \hat{r}_{\ell^*} + 2d^* g_{\ell^*}.$$

6. Compute  $\sigma_{i^*} := \text{Mod}(k_{i^*}, w_{j^*})$ , and derive the session key  $\text{sk}_{i^*} \leftarrow H_2(\text{id}_{i^*}, \text{id}_{j^*}, x_{i^*}, y_{j^*}, w_{j^*}, \sigma_{i^*})$ .
- Upon the query of  $\text{Test}(\Pi_2, I, \text{id}_{i^*}, \text{id}_{j^*}, x_{i^*}, (y_{j^*}, w_{j^*}))$ ,  $\mathcal{S}$  chooses  $b \leftarrow \mathbb{B}$ , and  $\text{sk}'_{i^*} \leftarrow \mathbb{B}^\lambda$ ; If  $b = 0$ ,  $\text{sk}'_{i^*}$  is returned, or else  $\text{sk}_{i^*}$  is returned.

Game  $G_{2,5}$  is pretty similar to  $G_{2,4}$ , and hence only the differences are listed below. In  $G_{2,5}$ ,  $\mathcal{S}$  generates the table

$$T' \triangleq \{ (v_{0,k}, v_{1,k}) \mid 1 \leq k \leq \ell, v_{0,k}, v_{1,k} \leftarrow \mathcal{R}_q \}$$

Moreover, the only difference between  $G_{2,4}$  and  $G_{2,5}$  is that, in  $G_{2,5}$ :

- Upon the query of  $\text{Send}_2(\Pi_2, I, \text{id}_{i^*}, \text{id}_{j^*}, \mathbf{x}_{i^*}, (\mathbf{y}_{j^*}, \mathbf{w}_{j^*}))$ ,  $\mathcal{S}$  proceeds as follow:
  1. Randomly choose  $\mathbf{k}_{i^*} \leftarrow \mathcal{R}_q$ ;
  2. Compute  $\sigma_{i^*} := \text{Mod}(\mathbf{k}_{i^*}, \mathbf{w}_{j^*})$ , and derive the session key  $\text{sk}_{i^*} \leftarrow H_2(\text{id}_{i^*}, \text{id}_{j^*}, \mathbf{x}_{i^*}, \mathbf{y}_{j^*}, \mathbf{w}_{j^*}, \sigma_{i^*})$ .

Note that, in  $G_{2,5}$ , when  $\mathcal{S}$  answers the  $\text{Send}_0$  oracle query for the test session, the value  $\hat{\mathbf{x}}_{i^*} := \mathbf{v}_{0,\ell^*}$  follows the uniform distribution over  $\mathcal{R}_q$  according to the table  $T'$  set by  $\mathcal{S}$ .

## 7.2 Analysis on the Proof of Claim 16

The proof of Claim 16 (in accordance with our communications with the corresponding author) considers any PPT adversary  $\mathcal{A} = (\mathcal{A}_1, \mathcal{A}_2)$ , which could be divided into two *consecutive* stages  $\mathcal{A}_1$  and  $\mathcal{A}_2$ .  $\mathcal{A}_1$  denotes the actions of  $\mathcal{A}$  until it just gets the RO-answer  $\mathbf{d}^* \leftarrow H_1(\text{id}_{j^*}, \text{id}_{i^*}, \mathbf{y}_{j^*}, \mathbf{x}_{i^*})$ . Let  $\text{view}_1 \triangleq (\mathbf{x}_{i^*}, \mathbf{y}_{j^*}, \mathbf{d}^*, \mathbf{p}_{j^*}, \mathbf{p}_{i^*}, \mathbf{c}^*, \mathbf{a}, \mathbf{tr}, \mathbf{st})$  be the output of  $\mathcal{A}_1$  (to  $\mathcal{A}_2$ ), where  $\mathbf{tr}$  denotes the view of  $\mathcal{A}_1$  in other sessions other than the test session, and  $\mathbf{st}$  denotes some state information. On input of  $\text{view}_1$ ,  $\mathcal{A}_2$  performs the remaining actions of  $\mathcal{A}$ .

Thanks to deep discussions with the author in charge of the proof of Claim 16 [ZZDS14], we could figure out more detailed explanations for the proof and reach some consensus as follows.

- Under the ring-LWE assumption, the output (*i.e.*,  $\text{view}_1$ ) of  $\mathcal{A}_1$  in  $G_{2,4}$  is computationally indistinguishable from that of  $\mathcal{A}_1$  in  $G_{2,5}$ .
- In the RO model, in order for  $\mathcal{A}_2$  to succeed, it has to make the RO-query  $H_2(\text{id}_{i^*}, \text{id}_{j^*}, \mathbf{x}_{i^*}, \mathbf{y}_{j^*}, \mathbf{w}_{j^*}, \sigma_{i^*})$  with non-negligible probability. This means that *except with negligible probability*, a successful  $\mathcal{A}_2$  has to compute  $\sigma_{i^*} := \text{Mod}(\mathbf{k}_{i^*}, \mathbf{w}_{j^*})$ .
- The actions of  $\mathcal{A}_2$  essentially makes no essential contribution to its ability of computing  $\sigma_{i^*} := \text{Mod}(\mathbf{k}_{i^*}, \mathbf{w}_{j^*})$ , even if  $\mathcal{A}_2$  could maliciously set  $\mathbf{w}_{j^*}$  in its stage. In other words, for a successful  $\mathcal{A}_2$ , its ability of computing  $\sigma_{i^*}$  mainly stems from the output  $\text{view}_1$  of  $\mathcal{A}_1$ .
- The probability that  $\mathcal{A}_2$  could compute  $\sigma_{i^*}$  in  $G_{2,5}$  is negligible, as in the RO model  $\mathbf{k}_{i^*}$  is a random value independent of the view of  $\mathcal{A}$  in  $G_{2,5}$ .
- In the proof of Claim 16 in [ZZDS14], it also uses the forking lemma to argue some extra properties. According to our discussions with the corresponding author of Claim 16, the use of forking lemma is actually unnecessary for proving Claim 16, and thus the reasoning related to forking lemma can be removed.

Now comes the divarication. The corresponding author of Claim 16 suggests that the above facts have already been sufficient to reach the final conclusion: the probability that  $\mathcal{A}_2$  outputs  $\sigma_{i^*} := \text{Mod}(\mathbf{k}_{i^*}, \mathbf{w}_{j^*})$  in  $G_{2,4}$  is also negligible.

From our view, to reach this final conclusion, we need to additionally argue that the joint distribution of  $(\text{view}_1, \mathbf{k}_{i^*})$  in  $G_{2,4}$  and that in  $G_{2,5}$  are computationally indistinguishable, because the event in question is defined over both  $\text{view}_1$  and  $\mathbf{k}_{i^*}$ . In particular, we need to at least argue the computational indistinguishability between  $\mathbf{k}_{i^*}$  defined over  $G_{2,4}$  and the uniform distribution over  $\mathcal{R}_q$  (that is just the distribution of  $\mathbf{k}_{i^*}$  in  $G_{2,5}$ ), which is, however, explicitly claimed to be unnecessary by the author of Claim 16.

**Key differences between  $G_{2,4}$  and  $G_{2,5}$ , and subtleties buried** To make the analysis clearer, we would like to highlight some key differences between  $G_{2,4}$  and  $G_{2,5}$  explicitly.

Firstly, in game  $G_{2,5}$ , the random variables  $\mathbf{k}_{i^*}$  and  $\mathbf{x}_{i^*}$  are *independent*. However this is not the case in game  $G_{2,4}$ , since  $\mathbf{x}_{i^*} = \mathbf{a}\hat{\mathbf{r}}_{\ell^*} + 2\hat{\mathbf{f}}_{\ell^*} - \mathbf{p}_{i^*}\mathbf{c}^*$  and  $\mathbf{k}_{i^*} = \mathbf{d}^*(\mathbf{p}_{j^*}\hat{\mathbf{r}}_{\ell^*} + 2\mathbf{g}_{\ell^*}) + \mathbf{y}_{j^*}\hat{\mathbf{r}}_{\ell^*}$  are related by  $\hat{\mathbf{r}}_{\ell^*}$ , making them *dependent*. In other words, in game  $G_{2,4}$ , when  $\mathbf{x}_{i^*}$  is given to the efficient adversary  $\mathcal{A}$ , it might be possible for  $\mathcal{A}$  to extract some information regarding  $\mathbf{k}_{i^*}$ .

Secondly, given that in  $G_{2,4}$  we have  $\mathbf{x}_{i^*} = \mathbf{a}\hat{\mathbf{r}}_{\ell^*} + 2\hat{\mathbf{f}}_{\ell^*} - \mathbf{p}_{i^*}\mathbf{c}^*$  and  $\mathbf{k}_{i^*} := \mathbf{d}^*\mathbf{v}_{1,\ell^*} + \mathbf{y}_{j^*}\hat{\mathbf{r}}_{\ell^*} = (\mathbf{p}_{j^*}\mathbf{d}^* + \mathbf{y}_{j^*})\hat{\mathbf{r}}_{\ell^*} + 2\mathbf{d}^*\mathbf{g}_{\ell^*}$ , the values  $(\mathbf{x}_{i^*}, \mathbf{y}_{j^*}, \mathbf{d}^*, \mathbf{p}_{j^*}, \mathbf{p}_{i^*}, \mathbf{c}^*, \mathbf{a})$  essentially determine the value  $\mathbf{k}_{i^*} - 2\mathbf{d}^*\mathbf{g}_{\ell^*}$ . In view that  $2\mathbf{d}^*\mathbf{g}_{\ell^*}$  is small, the value  $\mathbf{k}_{i^*}$  is essentially committed to  $(\mathbf{x}_{i^*}, \mathbf{y}_{j^*}, \mathbf{d}^*, \mathbf{p}_{j^*}, \mathbf{p}_{i^*}, \mathbf{c}^*, \mathbf{a})$  up to a “small” and even noise.

Finally, notice that in  $G_{2,4}$ , for the equation  $\mathbf{k}_{i^*} = \mathbf{d}^*\mathbf{v}_{1,\ell^*} + \mathbf{y}_{j^*}\hat{\mathbf{r}}_{\ell^*}$ , the two terms on the right-hand side are not independent either. Thus, it is not that easy to analyze the *exact* distribution of  $\mathbf{k}_{i^*}$ .

These highlighted differences indicate that the above facts *by consensus* are insufficient to establish the indistinguishability between  $\mathbf{k}_{i^*}$  defined over  $G_{2,4}$  and the uniform distribution over  $\mathcal{R}_q$ . Actually, we even do not know how to *formally* prove, with a reducibility argument, a seemingly easier goal: given  $\mathbf{x}_{i^*} = \mathbf{a}\hat{\mathbf{r}}_{\ell^*} + 2\hat{\mathbf{f}}_{\ell^*} - \mathbf{p}_{i^*}\mathbf{c}^*$ , it is infeasible for any efficient  $\mathcal{A}_2$  to successfully recover  $\mathbf{h}_{i^*} \triangleq (\mathbf{p}_{j^*}\mathbf{d}^* + \mathbf{y}_{j^*})\hat{\mathbf{r}}_{\ell^*}$  by maliciously setting  $\mathbf{y}_{j^*}$  and  $\mathbf{w}_{j^*}$  (recall that  $\mathbf{k}_{i^*} = \mathbf{h}_{i^*} + 2\mathbf{d}^*\mathbf{g}_{\ell^*}$  where  $2\mathbf{d}^*\mathbf{g}_{\ell^*}$  is even and “small”). Notice that, conditioned on  $\mathcal{A}_2$  recovers

$\mathbf{h}_{i^*}$ , by setting  $\mathbf{w}_{j^*} := \text{Parity}(\mathbf{h}_{i^*})$  it can then determine the value of  $\sigma_{i^*}$  and thus break the security, since the following holds *w.o.p.*:

$$\sigma_{i^*} = \text{Mod}(\mathbf{k}_{i^*}, \mathbf{w}_{j^*}) = \text{Mod}(\mathbf{h}_{i^*} + 2d^* \mathbf{g}_{\ell^*}, \text{Parity}(\mathbf{h}_{i^*})) = \text{Mod}(\mathbf{h}_{i^*}, \text{Parity}(\mathbf{h}_{i^*})).$$

The above clarifications also indicate a fundamental difference between the security proof of HMQV [Kra05] and that of its RLWE-based analogue [ZZD<sup>+</sup>15]. In the security proof of HMQV [Kra05], the simulator can *directly* obtain, from RO-query, the key material (corresponding to  $\mathbf{k}_{i^*}$  in [ZZD<sup>+</sup>15]) in order to reach reduction contradiction to the underlying gap Diffie-Hellman assumption. However, in the security proof of RLWE-based HMQV-analogue [ZZD<sup>+</sup>15], the simulator gets, also from RO-query, only the value  $\sigma_{i^*} := \text{Mod}(\mathbf{k}_{i^*}, \mathbf{w}_{j^*})$ , where the key material  $\mathbf{k}_{i^*}$  is hidden and  $\mathbf{w}_{j^*}$  may be maliciously set only in the stage of  $\mathcal{A}_2$ . From our view, these buried subtleties need to be dealt with explicitly in a formal analysis.

**Justification with simplified analogous games** To further justify our observations, we consider a pair of simplified analogous games  $(G_0, G_1)$  w.r.t. a special PPT adversary  $\mathcal{A} = (\mathcal{A}_1, \mathcal{A}_2)$ . These simplified games are artificial and are actually unrelated to  $G_{2,4}$  and  $G_{2,5}$ , which are introduced for easier logic explanation. In both games,  $\mathcal{A}$  gets access to a random oracle  $H : \{0, 1\}^\lambda \rightarrow \{0, 1\}^\lambda$  that is maintained and simulated by a PPT simulator  $S$ , where  $\lambda$  is the security parameter. Denote by  $Com$  a computationally hiding commitment scheme used also in these games.

In game  $G_0$  (resp.,  $G_1$ ),  $S$  simulates the random oracle  $H$  with another random oracle  $H' : \{0, 1\}^{2\lambda} \rightarrow \{0, 1\}^\lambda$  as follows. Before the game starts, it sets  $pre = 0^\lambda$  (resp.,  $pre \leftarrow \{0, 1\}^\lambda$ , *i.e.*,  $pre$  is a value taken uniformly at random from  $\{0, 1\}^\lambda$  in  $G_1$ ). Whenever the adversary makes an RO-query with  $x \in \{0, 1\}^\lambda$ , it returns the value  $y = H'(pre||x)$ . Notice that, from the view of  $\mathcal{A}$ , the RO simulation of  $S$  is perfect. At the end of  $\mathcal{A}_1$ ,  $S$  computes  $C = Com(0^\lambda)$  (resp.,  $C = Com(pre')$ , where  $pre' \leftarrow \{0, 1\}^\lambda$  is independent of  $pre$ ), and gives  $C$  to  $\mathcal{A}_1$ . Define  $view_1 = (C, tr, st)$  the output of  $\mathcal{A}_1$ , on which  $\mathcal{A}_2$  proceeds further. Finally,  $\mathcal{A}_2$  just simply outputs  $0^\lambda$ .

For the above simplified analogous games, we have: (1) The output of  $\mathcal{A}_1$  in  $G_0$  is computationally indistinguishable from that in  $G_1$ ; (2) The actions of  $\mathcal{A}_2$  make no contribution to its ability of computing  $pre$ ; (3) Clearly, in  $G_2$ , the probability that  $\mathcal{A}_2$  correctly outputs  $pre$  with probability of just  $2^{-\lambda}$  in the RO model, as  $pre$  is a random value actually independent of  $\mathcal{A}$ 's view in this case. However, we couldn't reach the conclusion that  $\mathcal{A}_2$  will also output  $pre$  with negligible probability in  $G_0$ . Actually, the success probability of  $\mathcal{A}_2$  in  $G_0$  is 1. The reason is just that the success event of  $\mathcal{A}_2$  is defined not only over its view but also over the "hidden" value  $pre$ , which is  $0^\lambda$  in  $G_0$  clearly distinguishable from a random value in  $G_2$ .

## A Communications with the Corresponding Authors of [ZZD<sup>+</sup>15,ZZDS14] about the Security Proof of $\Pi_2$

We have made deep discussions with the corresponding authors of [ZZD<sup>+</sup>15,ZZDS14] *in regard to the security proof of  $\Pi_2$* . Here, we briefly report the results from the communications, *which is only for the reference of referees*.

The technical details of the small field attack against  $\Pi_1$  are examined by one corresponding author and his students, and the validity is explicitly confirmed.

Unfortunately, we could not reach a final consensus from the communications with the corresponding author of Claim 16, *i.e.*, an intermediate claim in the security proof of  $\Pi_2$ . To be frank, the analysis of Claim 16 in [ZZDS14] is over sketchy, and the logic is elusive there. Moreover, according to our communications, the parts related to forking lemma in the analysis of Claim 16 is unnecessary and can be removed there (as explicitly acknowledged by the corresponding author), which results in a further sketched proof. Thanks to the deep discussions, we still reach some important consensus with the corresponding author on the proof details of Claim 16, as presented in Section 7. However, we have a fundamental diverge in reaching the final conclusion. It is unfortunate that, after we made clear of the subtleties related to the divarication, the corresponding author refused further communications. As a consequence, we could not explicitly state our final conclusion on the security proof of Claim 16, but present our observations and clarifications and leave drawing the final conclusion to the reader.

## B The Algorithms $\mathcal{A}'_1$ and $\mathcal{V}$ in Pseudocode

### B.1 The Algorithm $\mathcal{A}'_1$

---

**Algorithm 1** The algorithm  $\mathcal{A}'_1$

---

```

1: procedure  $(\mathcal{A}'_1)^{\mathcal{M}_1}(i, \{s_1, \dots, s_{i-1}\})$ 
2:   Choose  $g \in \mathbb{F}_q^\times$  such that  $g$  is a primitive element of  $\mathbb{F}_q$ ;
3:    $d := q_0/n$ ;
4:   for every  $\tilde{s}_i \in \mathbb{F}_q$  do
5:     for every  $k \in \{g^r \mid r \in [d]\}$  do
6:       for every  $r \in [i-1]$  do
7:          $h_{k,r} \leftarrow \mathbb{F}_q^\times$ ; ▷ Generate nonzero  $h_{k,r} \in \mathbb{F}_q$  randomly
8:       end for
9:        $\mathbf{h}_k := \sum_{r \in [i-1]} h_{k,r} \cdot \mathbf{c}_r$ ; ▷ Generate the random  $\mathbf{h}_k$ 
10:       $\mathbf{e}_k \leftarrow \mathbb{Z}_{1+2\alpha'\sqrt{n}}^n$ ; ▷ Generate the small noise  $\mathbf{e}_k$ 
11:      for every  $j \in [n]$  do
12:         $u_{k,j} := \tilde{s}_i \cdot k c_{i,j} + \sum_{r \in [i-1]} s_r h_{k,r} c_{r,j}$ ;
13:         $w_{k,j} := \text{Cha}(u_{k,j})$ ; ▷ Set the desired  $w$ -entry
14:         $z_{k,j} := \text{Mod}(u_{k,j}, w_{k,j})$ ; ▷ Set the desired  $z$ -entry
15:      end for
16:       $b_k \leftarrow \mathcal{M}_1(k \cdot \mathbf{c}_i + \mathbf{h}_k + 2\mathbf{e}_k, [w_{k,j}]_{j \in [n]}, [z_{k,j}]_{j \in [n]})$ ; ▷ Invoke  $\mathcal{M}_1$ 
17:    end for
18:    if  $b_k = 1$  for every  $k \in \{g^r \mid r \in [d]\}$  then
19:      return  $\tilde{s}_i$ ; ▷ This implies the guess  $s_i = \tilde{s}_i$  is correct
20:    end if
21:  end for
22:  return  $\perp$ ;
23: end procedure
