Abstract

We present a new approach towards constructing round-optimal secure multiparty computation (MPC) protocols against malicious adversaries without trusted setup assumptions. Our approach builds on ideas previously developed in the context of covert multiparty computation [Chandran et al., FOCS'07] even though we do not seek covert security. Using our new approach, we obtain the following results:

- A five round MPC protocol based on the Decisional Diffie-Hellman (DDH) assumption.
- A four round MPC protocol based on one-way permutations and sub-exponentially secure DDH. This result is *optimal* in the number of rounds.

Previously, no four-round MPC protocol for general functions was known and five-round protocols were only known based on indistinguishability obfuscation (and some additional assumptions) [Garg et al., EUROCRYPT'16].

1 Introduction

The notion of secure multiparty computation (MPC) [Yao86, GMW87] is fundamental in cryptography. Informally speaking, an MPC protocol allows mutually distrusting parties to jointly evaluate a function on their private inputs in such a manner that the protocol execution does not leak anything beyond the output of the function.

A fundamental measure of efficiency in MPC is round complexity, i.e., the number of rounds of communication between the parties. Protocols with smaller round complexity are more desirable so as to minimize the effect of network latency, which in turn decreases the time complexity of the protocol. Indeed, the round complexity of MPC has been extensively studied over the last three decades.

In this work, we study round-optimal MPC against malicious adversaries who may corrupt an arbitrary subset of parties, in the plain model without any trusted setup assumptions. We consider the traditional simultaneous message model for MPC, where in each round of the protocol, each party simultaneously broadcasts a message to the other parties.

A lower bound for this setting was established last year by Garg et al. [GMPP16] who proved that three rounds are insufficient for coin-tossing w.r.t. black-box simulation. (Their work builds on [KO04] who proved the necessity of five rounds for coin-tossing in the unidirectional message model.) In the positive direction, several constant-round MPC protocols were constructed in a long sequence of works, based on a variety of assumptions and techniques (see, e.g., [KOS03, Pas04, PW10, Wee10, Goy11]). Garg et al. [GMPP16] established an upper bound on the exact round complexity of MPC by constructing a *five* round protocol based on indistinguishability obfuscation [BGI+01, GGH+13] and some additional

assumptions.¹ Their work constitutes the state of the art on this subject.

Our Goals. Presently, no constructions of indistinguishability obfuscation are known from standard assumptions. This motivates the following important question:

Does there exist a five round maliciously-secure MPC protocol for general functions based on standard polynomial-time assumptions?

Furthermore, given the gap between the lower bound (three rounds) and the upper bound (five rounds) established by [GMPP16], we ask whether their upper bound is tight:

Does there exist a four round maliciously-secure MPC protocol for general functions?

In this work, we resolve both of these questions in the affirmative.

The Main Barrier. We highlight the main conceptual barrier towards achieving our goals. Garg et al. [GMPP16] follow a natural two-step approach to obtain their positive results: in the first step, they construct a four round multiparty coin-tossing protocol. In the next step, they use their coin-tossing protocol to replace the common random string (CRS) in a two-round MPC protocol in the CRS model [GGHR14, MW16].

We note, however, that this approach, in general, cannot do better than five rounds. Indeed, since at least one of the rounds of the two-round MPC must depend upon the CRS, we can only hope to parallelize its first round with the coin-tossing protocol. Since coin-tossing requires four rounds, this only yields a five round protocol at best.

A New Approach. In this work, we present a new approach towards constructing round-optimal MPC protocols in the plain model. At a high level, our approach implements the classical GMW methodology [GMW87] for constructing maliciously-secure MPC protocols, *with a crucial twist*, to minimize the number of rounds.

Recall that the GMW compiler transforms a semi-honest MPC protocol into a maliciously secure one by requiring the parties to prove (using zero-knowledge proofs [GMR85]) that each message in the semi-honest protocol was computed “honestly.” For our goals, we cannot afford to prove honest behavior with every round of semi-honest MPC.² Therefore, in our approach, the parties prove honest behavior only *once*.

At first, such an approach may sound completely absurd. If each party is only required to give a single proof to establish honest behavior, then a malicious adversary may choose to cheat in the first few rounds of the semi-honest MPC protocol. By the time the proof is completed and the honest parties are able to detect cheating, it may already be “too late.” Indeed, the opportunity to cheat in even a single round may be sufficient for a malicious adversary to completely break the security of a semi-honest protocol. Therefore, it is not at all clear why such an approach can be implemented in a secure manner.

In order to tackle this problem, we build on ideas previously developed in the beautiful work of Chandran et al. [CGOS07] for constructing covert multiparty computation protocols [vHL05, CGOS07, GJ10]. At a high level, we first design a “special-purpose” semi-honest MPC protocol that remains partially immune to malicious behavior before the last round of the protocol. Specifically, in such a protocol, an adversary can influence the protocol outcome but not learn any private information by behaving maliciously before the last round. We then “shield” the last round from being revealed to the adversary until it has proven honest behavior for all of the preceding rounds. A single proof suffices to accomplish this task. By parallelizing this proof with the semi-honest MPC, we are able to minimize the round complexity.

¹Garg et al. also construct a four-round protocol for the coin-tossing functionality. In this work, we are interested in MPC for general functions.

²It is known that semi-honest MPC requires at least two rounds [HLP11] and zero-knowledge proofs require at least three rounds [GO94]. Therefore, implementing the standard GMW methodology would require at least six rounds.

1.1 Our Results

We present a new approach for constructing round-efficient MPC protocols that are secure against malicious adversaries in the plain model. Using this approach, we are able to achieve both of our aforementioned goals.

I. Robust Semi-honest MPC. As a first step towards obtaining our results for maliciously-secure MPC, we construct a four round *robust* semi-honest MPC protocol that remains partially immune to malicious behavior. In this protocol, at the end of the first three rounds of computation, each party receives a secret share of the function output. In the last round, the parties simply exchange their shares to reconstruct the output. The key security property of this protocol is that if the adversary cheats in the first three rounds, then it can only influence the function output, but not learn any private information.

We construct such an MPC scheme for general functions assuming the existence of low-depth pseudorandom generators (PRGs) and a two-round “covert” oblivious transfer (OT) protocol [vHL05].³ Both of these primitives can be instantiated from the Decisional Diffie-Hellman (DDH) assumption.

Theorem 1. *Assuming DDH, there exists a four round robust semi-honest MPC protocol for general functions.*

The above result may be of independent interest.

II. Maliciously-secure MPC. Using theorem 1, we next construct maliciously-secure MPC protocols in the plain model.

Our first result is a five round MPC protocol based on any four-round robust semi-honest MPC, injective one-way functions and collision-resistant hash functions (CRHFs). Since injective one-way functions and CRHFs can be built from Discrete Log, we obtain the following result:

Theorem 2 (Five Rounds). *Assuming DDH, there exists a five round maliciously-secure MPC protocol for computing general functions.*

We next modify our five round protocol to obtain a four round protocol, albeit using sub-exponential hardness. The security of our construction uses complexity leveraging between multiple primitives.

Theorem 3 (Four Rounds). *Assuming one-way permutations and sub-exponentially secure DDH, there exists a four round maliciously-secure MPC protocol for computing general functions.*

1.2 Our Techniques

As discussed earlier, the approach of Garg et al. [GMPP16] for constructing maliciously-secure MPC protocols is unsuitable for achieving our goals. Therefore, we develop a new approach for constructing round-efficient MPC against malicious adversaries.

At a high-level, our approach implements the GMW paradigm for constructing maliciously-secure MPC protocols, with a crucial twist. Recall that the GMW paradigm transforms a semi-honest MPC protocol into a maliciously secure one using the following three steps: (1) first, the parties commit to their inputs and random tapes. (2) Next, the parties perform coin-tossing to establish an unbiased random tape for each party. (3) Finally, the parties run the semi-honest MPC protocol where along with every message, each party also gives zero-knowledge proof of “honest” behavior consistent with the committed input and random tape.

Both steps (2) and (3) above introduce additional rounds of interaction, and constitute the main bottleneck towards constructing round-optimal MPC.

Main Ideas. Towards this, we develop two key modifications to the GMW compiler:

³We use low-depth PRGs to obtain degree-three randomizing polynomials for general functions [AIK06].

1. **“One-shot” proof:** Instead of requiring the parties to give a proof of honest behavior in each round of the underlying semi-honest protocol, we use a “delayed verification” technique where the parties prove honest behavior only *once*, towards the end of the protocol. As we explain below, this allows us to limit the overhead of additional rounds introduced by zero-knowledge proofs in the GMW compiler.

The idea of delayed verification was previously developed in the work of Goyal et. al. [CGOS07]. Interestingly, while they used this technique to achieve security in the setting of covert computation [vHL05, CGOS07], we use this technique to minimize the round complexity of our protocol.

2. **No coin tossing:** Second, we eliminate the coin-tossing step (i.e., step 2). Note that by removing coin-tossing, we implicitly allow the adversarial parties to potentially use “bad” randomness in the protocol. To ensure security in this scenario, we will use a special semi-honest MPC protocol that is secure against bad randomness. This idea has previously been used in many works (see, e.g., [AJL⁺12, MW16]).

We now elaborate on the first step, which constitutes the conceptual core of our work. We consider semi-honest MPC protocols with a specific structure consisting of two phases: (a) *Computation phase*: in the first phase of the protocol, the parties compute the function such that each party obtains a secret-share of the output. (b) *Output phase*: In the second phase, the parties exchange their output shares with each other to compute the final output. This phase consists of only one round and is deterministic. Note that standard MPC protocols such as [GMW87] follow this structure.

At a high-level, we implement our delayed verification strategy as follows: the parties first run the computation phase of the semi-honest protocol “as is” without giving any proofs. At the end of this phase, each party gives a single proof that it behaved honestly throughout the computation phase (using the committed input and random tape). If all the proofs verify, then the parties execute the output phase.

Right away, one may notice a glaring problem in the above approach. If the computation phase is executed without any proof of honest behavior, the adversary may behave maliciously in this phase and potentially learn the honest party inputs even before the output phase begins! Indeed, standard semi-honest MPC protocols do not guarantee security in such a setting.

To combat this problem, we develop a special purpose semi-honest MPC protocol that remains “partially immune” to malicious behavior. Specifically, such a protocol maintains privacy against malicious adversaries *until the end of the computation phase*. However, output correctness is not guaranteed if the adversary behaved maliciously in the computation phase. We refer to such an MPC protocol as *robust semi-honest MPC*. Later, we describe a four-round construction of robust semi-honest MPC where the first three rounds correspond to the computation phase and the last round constitutes the output phase.

Note that the robustness property as described above perfectly suits our requirements because in our compiled protocol, the output phase is executed only after each party has proven that it behaved honestly during the computation phase. This ensures full security of our compiled protocol.

A New Template for Malicious MPC. Putting the above ideas together, we obtain the following new template for maliciously-secure MPC:

- First, each party commits to its input and randomness using a three-round extractable commitment scheme.⁴ In parallel, the parties also execute the computation phase of a four-round robust semi-honest MPC.
- Next, each party proves to every other party that it behaved honestly during the first three rounds.

⁴We use a variant of the extractable commitment scheme in [Ros04] for this purpose. This variant has been used in many prior works such as [GJO10, GGJS12, Goy12] because it is “rewinding secure” – a property that is used in the security proofs.

- Finally, the parties execute the output phase of the robust semi-honest MPC and once again prove that their message is honestly computed.

In order to obtain a five round protocol from this template, we need to parallelize the proofs with the other protocol messages. For this purpose, we use delayed-input proofs [LS90] where the instance is only required in the last round.⁵ In particular, we use four-round delayed input zero-knowledge (ZK) proofs whose first three messages are executed in parallel with the first three rounds of the robust semi-honest MPC. This yields us a five round protocol.

We remark that during simulation, our simulator is able to extract the adversary’s input only at the end of the third round. This means that we need to simulate the first three rounds of the robust semi-honest MPC without knowledge of the adversary’s input (or the function output). Our robust semi-honest MPC satisfies this property; namely, the simulator for our robust semi-honest MPC needs the adversary’s input and randomness (and the function output) only to simulate the output phase.

Four Rounds: Main Ideas. We next turn to the problem of constructing four-round MPC. At first, it is not clear how to obtain a four round protocol using the above template. Indeed, as argued earlier, we cannot afford to execute the output phase without verifying that the parties behaved honestly during the computation phase. In the above template, the output phase is executed *after* this verification is completed. Since three-round zero-knowledge proofs with polynomial-time simulation are not known presently, the verification process in the above protocol requires four rounds. Therefore, it may seem that that we are limited to a five round protocol.

Towards that, we note that our robust semi-honest MPC (described later) satisfies the following property: in order to simulate the view of the adversary (w.r.t. the correct output), the simulator only needs to “cheat” in the output phase (i.e., the last round). In particular, the simulation of the computation phase can be done “honestly” using random inputs for the honest parties. In this case, we do not need full-fledged ZK proofs to establish honest behavior in the computation phase; instead, we only need *strong* witness indistinguishable (WI) proofs. Recall that in a strong WI proof system, for any two indistinguishable instance distributions D_1 and D_2 , a proof for $x_1 \leftarrow D_1$ using a witness w_1 is indistinguishable from a proof for $x_2 \leftarrow D_2$ using a witness w_2 . This suffices for us because using strong WI, we can switch from an honest execution of the computation phase using the real inputs of the honest parties to another honest execution of the computation phase using random inputs for the honest parties.

Recently, Jain et al. [JKKR17] constructed three-round delayed-input strong WI proofs of knowledge from the DDH assumption. However, their proof system only guarantees strong WI property if the entire statement is chosen by the prover in the last round. In our case, this is unfortunately not true, and hence we cannot use their construction. Therefore, we take a different route, albeit at the cost of sub-exponential hardness assumptions. Specifically, we observe that by relying upon sub-exponential hardness, we can easily construct a three-round (delayed-input) strong WI argument by combining any three-round (delayed-input) WI proof of knowledge with a one or two-message “trapdoor phase” in our simultaneous message setting. For example, let f be a one-way permutation. The trapdoor phase can be implemented by having the verifier send $y = f(x)$ for a random x in parallel with the first prover message. The statement of the WI proof of knowledge is changed to: either the original statement is true or the prover knows x .

Now, by running in exponential time in the hybrids, we can break the one-way permutation to recover x and then prove knowledge of x . This allows us to switch from honest execution of the computation phase using the real inputs of the honest parties to another honest execution using random inputs. After this switch, we can go back to proving the honest statement which can be done in polynomial time. This ensures that our final simulator is also polynomial time.

Handling Non-malleability Issues. So far, we ignored non-malleability related issues in our discussion. However, as noted in many prior works, zero-knowledge proofs with standard soundness guarantee do

⁵Note that the witness for these proofs corresponds to the adversary’s input and random tape which is already fixed in the first round.

not suffice in the setting of constant-round MPC. Indeed, since proofs are being executed in parallel, we need to ensure that an adversary’s proofs remain sound even when the honest party’s proofs are being simulated [Sah99].

We handle such malleability issues by using the techniques developed in a large body of prior works. In our five round MPC protocol, we use the four-round non-malleable zero-knowledge (NMZK) argument of [COSV16] to ensure that adversary’s proofs remain sound even during simulation.⁶ We make non-black-box use of their protocol in our security proof. More specifically, following prior works such as [BPS06, GJO10, GGJS12, Goy12], we establish a “soundness lemma” to ensure that the adversary is behaving honestly across the hybrids. We use the extractability property of the non-malleable commitment used inside the non-malleable zero-knowledge argument to prove this property.

In our four round protocol, we use the above NMZK to prove honest behavior in the output phase. In order to prove honest behavior in the computation phase, we use a slightly modified version of the strong WI argument system described above which additionally uses a two-round non-malleable commitment [KS17] to achieve the desired non-malleability properties. Unlike the five round construction, here, we rely upon complexity leveraging in several of the hybrids to argue the “soundness lemma” as well as to tackle some delicate rewinding-related issues that are commonplace in such proofs.⁷ We refer the reader to the technical sections for details.

Robust Semi-honest MPC. We now briefly describe the high-level ideas in our four-round construction of robust semi-honest MPC for general functionalities. Towards this, we note that it suffices to achieve a simpler goal of constructing robust semi-honest MPC for a restricted class of functionalities, namely, for computing randomized encodings.⁸ That is, in order to construct a robust MPC for a n -party functionality F , it suffices to construct a robust MPC for a n -functionality F_{rnd} that takes as input $(x_1, r_1; \dots; x_n, r_n)$ and outputs a randomized encoding of $F(x_1, \dots, x_n)$ using randomness $r_1 \oplus \dots \oplus r_n$. This is because all the parties can jointly execute the protocol for F_{rnd} to obtain the randomized encoding. Each party can then individually execute the decoding algorithm of the randomized encoding to recover the output $F(x_1, \dots, x_n)$. Note that this transformation preserves round complexity.

To construct a robust semi-honest n -party protocol for F_{rnd} , we consider a specific type of randomized encoding defined in [AIK06]. In particular, they construct a degree 3 randomizing polynomials⁹ for arbitrary functionalities based on low-depth pseudorandom generators. In their construction, every output bit of the encoding can be computed by a degree 3 polynomial on the input and the randomness. Hence, we further break down the goal of constructing a protocol for F_{rnd} into the following steps:

- Step 1: Construct a robust semi-honest MPC 3-party protocol for computing degree 3 terms. In particular, at the end of the protocol, every party who participated in the protocol get a secret share $x_1x_2x_3$, where x_q is the q^{th} party’s input for $q \in \{1, 2, 3\}$. The randomness for the secret sharing comes from the parties in the protocol.
- Step 2: Using Step 1, construct a robust semi-honest MPC protocol to compute degree 3 polynomials.
- Step 3: Using Step 2, construct a robust semi-honest MPC protocol for F_{rnd} .

Steps 2 and 3 can be achieved using standard transformations and these transformations are round preserving. Thus, it suffices to achieve Step 1 in four rounds. Suppose P_1, P_2 and P_3 participate in the protocol. Roughly, the protocol proceeds as follows: P_1 and P_2 perform a two message covert OT protocol

⁶We also use the fact that argument system of [COSV16] allows for simulating multiple proofs executed in parallel.

⁷We believe that some of the use of complexity leveraging in our hybrids can be avoided by modifications to our protocol. We leave further exploration of this direction for subsequent work (see Remark 1 for a brief discussion).

⁸A randomized encoding of function f and input x is such that, the output $f(x)$ can be recovered from this encoding and at the same time, this encoding should not leak any information about either f or x .

⁹The terms randomized encodings and randomizing polynomials are interchangeably used.

to receive a share of x_1x_2 . Then, P_1 and P_3 perform a two message OT protocol to receive a share of $x_1x_2x_3$. We need to do more work to ensure that at the end, all of them have shares of $x_1x_2x_3$. Further, the robustness guarantee is argued using the covert security of the OT protocol. We refer the reader to the technical sections for more details.

1.3 Concurrent Work

In a concurrent and independent work, Brakerski, Halevi and Polychroniadou [BHP17] construct a four round MPC protocol against malicious adversaries using adaptive commitments [PPV08] and sub-exponentially secure learning with errors assumption. Their approach seems to depart significantly from ours in that they start from the two-round semi-honest MPC protocol of [MW16] and design a special-purpose coin-tossing protocol for it, while we construct a robust semi-honest MPC protocol that does not require coin-tossing. We also do not know whether their approach yields a five round protocol from standard assumptions.

We were made aware of the result statement of [BHP17] at a Darpa program meeting in March 2017. At that time, our four round MPC construction required stronger assumptions (in addition to the present ones). Since then, we have simplified our construction and the underlying assumptions.

1.4 Related Work

The study of constant-round protocols for MPC was initiated by Beaver et al. [BMR90]. Their constructed constant-round MPC protocols in the presence of honest majority. Subsequently, a long sequence of works constructed constant-round MPC protocols against dishonest majority based on a variety of assumptions and techniques (see, e.g., [KOS03, Pas04, PW10, Wee10, Goy11]). Very recently, Garg et al. [GMPP16] constructed five round MPC using indistinguishability obfuscation and three-round parallel non-malleable commitments. They also construct a six-round MPC protocol using learning with errors (LWE) assumption and three-round parallel non-malleable commitments. All of these results are in the plain model where no trusted setup assumptions are available.

Asharov et. al. [AJL⁺12] constructed three round MPC protocols in the CRS model. Subsequently, two-round MPC protocols in the CRS model were constructed by Garg et al. [GGHR14] using indistinguishability obfuscation, and by Mukherjee and Wichs [MW16] using LWE assumption.

2 Preliminaries

For the definitions of all the underlying primitives used in our constructions, we refer the reader to Appendix A. Below, we provide the definition of robust semi-honest MPC.

Robust Semi-Honest MPC. We consider semi-honest secure multi-party computation protocols that satisfy an additional *robustness* property. Intuitively the property says that, except the final round, the messages of honest parties reveal no information about their inputs even if the adversarial parties behave *maliciously*.

Definition 1. Let F be an n -party functionality. Let $\mathcal{A} = (\mathcal{A}^1, \mathcal{A}^2)$ represent a PPT algorithm controlling a set of parties $S \subseteq [n]$. For a t -round protocol computing F , we let $\text{RealExec}_{(t-1)}^{\mathcal{A}^1}(\vec{x}, z)$ denote the view of \mathcal{A}^1 during the first $t - 1$ rounds in the real execution of the protocol on input $\vec{x} = (x_1, \dots, x_n)$ and auxiliary input z . We require that at the end of the first $t - 1$ rounds in the real protocol, \mathcal{A}^1 outputs state and $(\text{inp}, \text{rand})$ on a special tape where either $(\text{inp}, \text{rand}) = (\perp, \perp)$ (if \mathcal{A}^1 behaved maliciously) or $(\text{inp}, \text{rand}) = (\{\hat{x}_i\}_{i \in S}, \{\hat{r}_i\}_{i \in S})$ which is consistent with the honest behavior for $\text{RealExec}_{(t-1)}$ (first $t - 1$ rounds).

A protocol is said to be a “**robust**” secure multiparty computation protocol for F if for every PPT adversary $\mathcal{A} = (\mathcal{A}^1, \mathcal{A}^2)$ controlling a set of parties S in the real world, where \mathcal{A}^2 is semi-honest, there exists a PPT simulator $\text{Sim} = (\text{Sim}^1, \text{Sim}^2)$ such that for every initial input vector \vec{x} , every auxiliary input z

– If $(\text{inp}, \text{rand}) \neq (\perp, \perp)$, then:

$$\begin{aligned} \left(\text{RealExec}_{(t-1)}^{\mathcal{A}^1}(\vec{x}, z), \text{RealExec}_t^{\mathcal{A}^2}(\vec{x}, \text{state}) \right) &\approx_c \left(\text{RealExec}_{(t-1)}^{\mathcal{A}^1}(\vec{x}, z), \text{Sim}^2(\{\widehat{x}_i\}_{i \in S}, \{\widehat{r}_i\}_{i \in S}, y, \text{state}) \right) \\ &\approx_c \left(\text{Sim}^1(z), \text{Sim}^2(\{\widehat{x}_i\}_{i \in S}, \{\widehat{r}_i\}_{i \in S}, y, \text{state}) \right). \end{aligned}$$

Here $y = F(\widehat{x}_1, \dots, \widehat{x}_n)$, where $\widehat{x}_i = x_i$ for $i \notin S$. And $\text{RealExec}_t^{\mathcal{A}^2}(\vec{x}, \text{state})$ is the view of adversary \mathcal{A}^2 in the t^{th} round of the real protocol.

– Else,

$$\text{RealExec}_{(t-1)}^{\mathcal{A}^1}(\vec{x}, z) \approx_c \text{Sim}^1(z).$$

Note that, in general, a semi-honest MPC protocol may not satisfy this property. In section 3, we construct a four-round semi-honest MPC protocol with robustness property.

3 Four Round Robust Semi-Honest MPC

We first describe the tools required for our construction. We require,

- Two message 1-out-of-2 covert oblivious transfer protocol (Theorem 11). Denote this by OT.
- Degree 3 randomizing polynomials for arbitrary polynomial sized circuits (Theorem 12). Denote this by RP = (CktE, D).

Both the tools mentioned above can be instantiated from DDH.

Construction. Our goal is to construct an n -party MPC protocol Π_{sh}^F secure against semi-honest adversaries for an n -party functionality F . Moreover, we show that Π_{sh}^F satisfies Robust property (Definition 1). We employ the following steps:

- **Step I:** We first construct an 3-party semi-honest MPC protocol $\Pi_{\text{sh}}^{\text{3MULT}}$ for the functionality 3MULT defined below. This protocol is a three round protocol. However, we view this as a four round protocol (with the last round being empty) – the reason behind doing this is because this protocol will be used as a sub-protocol in the next steps and in the proof, the programming of the simulator occurs only in the fourth round.

$$\text{3MULT}((x_1, r_1); (x_2, r_2); (x_3)) \text{ outputs } (r_1; r_2; x_1 x_2 x_3 + r_1 + r_2)$$

- **Step II:** We use $\Pi_{\text{sh}}^{\text{3MULT}}$ to construct an n -party semi-honest MPC protocol $\Pi_{\text{sh}}^{\text{3POLY}\{p\}}$ for the functionality 3POLY $\{p\}$ defined below, where p is a degree 3 polynomial in $\mathbb{F}_2[\mathbf{y}_1, \dots, \mathbf{y}_N]$. This protocol is a four round protocol and it satisfies robust property.

$$\text{3POLY}\{p\}(X_1; \dots; X_n) \text{ outputs } p(\mathbf{y}_1, \dots, \mathbf{y}_N),$$

where X_1, \dots, X_n are partitions of $\mathbf{y}_1, \dots, \mathbf{y}_N$.

- **Step III:** We use $\Pi_{\text{sh}}^{\text{3POLY}}$ to construct an n -party semi-honest MPC protocol Π_{sh}^F . This protocol is a four round protocol and it satisfies robust property.

We now describe the steps in detail.

Step I: Constructing $\Pi_{\text{sh}}^{3\text{MULT}}$. Denote the parties by P_1, P_2 and P_3 . Denote the input of P_1 to be (x_1, r_1) , the input of P_2 to be (x_2, r_2) and the input of P_3 to be (x_3) . The protocol works as follows:

- **Round 1:** P_1 participates in a 1-out-of-2 oblivious transfer protocol OT_{12} with P_2 . P_1 plays the role of receiver. It generates the first message of OT_{12} as a function of x_1 . Simultaneously, P_2 and P_3 participate in a 1-out-of-2 protocol OT_{23} . P_3 takes the role of the receiver. It generates the first message of OT_{23} as a function of x_3 .
- **Round 2:** P_2 sends the second message in OT_{12} as a function of $(x_2 \cdot 0 + r'_2; x_2 \cdot 1 + r'_2)$, where r'_2 is sampled at random. P_2 sends the second message in OT_{23} as a function of $(0 \cdot r'_2 + r_2; 1 \cdot r'_2 + r_2)$. Simultaneously, P_1 and P_3 participate in a OT protocol OT_{13} . P_3 takes the role of the receiver. It sends the first message of OT_{13} as a function of x_3 .
- **Round 3:** Let u be the value recovered by P_1 from OT_{12} . P_1 sends the second message to P_3 in OT_{13} as a function of $(u \cdot 0 + r_1, u \cdot 1 + r_1)$. Let α'_3 recovered from OT_{13} by P_3 and let α''_3 be the output recovered from OT_{23} .

P_1 outputs $\alpha_1 = r_1$, P_2 outputs $\alpha_2 = r_2$ and P_3 outputs $\alpha_3 = \alpha'_3 + \alpha''_3$ (operations performed over \mathbb{F}_2).

Theorem 4. *Assuming the correctness of OT , $\Pi_{\text{sh}}^{3\text{MULT}}$ satisfies correctness property.*

The proof can be found in [B.1](#).

Theorem 5. *Assuming the security of OT , $\Pi_{\text{sh}}^{3\text{MULT}}$ is a robust semi-honest three-party secure computation protocol satisfying Definition 1.*

The proof can be found in [B.2](#).

Step II: Constructing $\Pi_{\text{sh}}^{3\text{POLY}\{p\}}$. We first introduce some notation. Consider a polynomial $q \in \mathbb{F}_2[\mathbf{y}_1, \dots, \mathbf{y}_N]$ with coefficients over \mathbb{F}_2 . We define the set $\text{MonS}\{q\}$ as follows: a term $t \in \text{MonS}\{q\}$ if and only if t appears in the expansion of the polynomial q . We define $\text{MonS}\{q\}_i$ as follows: a term $t \in \text{MonS}\{q\}_i$ if and only if $t \in \text{MonS}\{q\}$ and t contains the variable \mathbf{y}_i .

We now describe $\Pi_{\text{sh}}^{3\text{POLY}\{p\}}$.

PROTOCOL $\Pi_{\text{sh}}^{3\text{POLY}\{p\}}$: Let P_1, \dots, P_n be the set of parties in the protocol. Let X_i be the input set of P_i for every $i \in [n]$. We have, $\sum_{i=1}^n |X_i| = N$ and $X_i \cap X_j = \emptyset$ for $i \neq j$. Every $x \in X_i$ corresponds to a unique variable \mathbf{y}_j for some j .

- For every $i \in [n]$, party P_i generates n additive shares $s_{i,1}, \dots, s_{i,n}$ of 0. It sends share $s_{i,j}$ to P_j in the first round.
- In parallel, for every term t in the expansion of p , do the following:
 - If t is of the form x_i^3 , then P_i computes x_i^3 .
 - If t is of the form $x_i^2 x_j$ then pick $k \in [n]$ and $k \neq i, k \neq j$. Let r_i^t and r_j^t be the randomness, associated with t , sampled by P_i and P_j respectively. The parties $P_i(x_i, r_i^t)$, $P_j(x_j, r_j^t)$ and $P_k(1)$ execute $\Pi_{\text{sh}}^{3\text{MULT}}$ to obtain the corresponding shares α_i^t, α_j^t and α_k^t . Note that this finishes in the third round.
 - If t is of the form $x_i x_j x_k$, then parties P_i, P_j and P_k sample randomness r_i^t, r_j^t and r_k^t respectively. Then, they execute $\Pi_{\text{sh}}^{3\text{MULT}}$ on inputs (x_i, r_i^t) , (x_j, r_j^t) and (x_k) to obtain the corresponding shares α_i^t, α_j^t and α_k^t . Note that this finishes in the third round.

- After the third round, P_i adds all the shares he has so far (including his own shares) and he broadcasts his final share s_i to all the parties. This consumes one round.
- Finally, P_i outputs $\sum_{i=1}^n s_i$.

Theorem 6. Assuming $\Pi_{\text{sh}}^{\text{3MULT}}$ satisfies correctness, $\Pi_{\text{sh}}^{\text{3POLY}\{p\}}$ satisfies correctness property.

The proof can be found in B.3.

Theorem 7. Assuming the security of $\Pi_{\text{sh}}^{\text{3MULT}}$, $\Pi_{\text{sh}}^{\text{3POLY}\{p\}}$ is a robust semi-honest MPC protocol satisfying Definition 1 as long as $\Pi_{\text{sh}}^{\text{3MULT}}$ satisfies Definition 1.

The proof can be found in B.4.

Step III: Constructing Π_{sh}^F . We describe Π_{sh}^F below.

PROTOCOL Π_{sh}^F : Let C be a circuit representing F . That is, $F(x_1; \dots, x_n) = C(x_1 || \dots || x_n)$. Let $\text{RP.CktE}(C) = (p_1, \dots, p_m)$. Note that p_i , for every i , is a degree 3 polynomial in $\mathbb{F}_2[\mathbf{y}_1, \dots, \mathbf{y}_n, \mathbf{r}_1, \dots, \mathbf{r}_N]$. Construct polynomial $\hat{p}_i \in \mathbb{F}_2[\mathbf{y}_1, \dots, \mathbf{y}_n, \mathbf{r}_{1,1}, \dots, \mathbf{r}_{n,N}]$ by replacing \mathbf{r}_j , for every $j \in [N]$, in p_i by the polynomial $\sum_{k=1}^n \mathbf{r}_{k,j}$. Note that \hat{p}_i is still a degree 3 polynomial.

P_i samples randomness $r_{i,j}$, for every $j \in [N]$. For every $j \in [m]$, all the parties execute the protocol $\Pi_{\text{sh}}^{\text{3POLY}\{\hat{p}_j\}}$. The input of P_i is $(x_i, r_{i,1}, \dots, r_{i,N})$ in this protocol. In the end, every party receives $\alpha_j = \hat{p}_j(x_1, \dots, x_n)$, for every $j \in [m]$. Every party then executes $\text{D}(\alpha_1, \dots, \alpha_n)$ to obtain α^* . It outputs α^* .

Theorem 8. Assuming the security of $\Pi_{\text{sh}}^{\text{3POLY}\{p\}}$ and security of RP, Π_{sh}^F is a robust semi-honest secure MPC protocol satisfying Definition 1 as long as $\Pi_{\text{sh}}^{\text{3POLY}\{p\}}$ satisfies Definition 1.

The proof can be found in B.5.

4 Five Round Malicious MPC

Overview. We start by giving an overview of our construction. We want to use the robust semi honest MPC as the basis for our construction, but its security is only defined in the semi-honest setting. We enforce the semi-honest setting by having the players prove, in parallel, that they computed the robust semi honest MPC honestly. Players prove that (1) they computed the first three rounds of the robust semi honest MPC honestly; and (2) they committed its input and randomness used in the robust semi honest MPC to every other party using an extractable commitment scheme. To do so, we use a four round input delayed proof system, where the statement for the proof can be delayed till the final round. This lets players send the final round of their proof in the fourth round. Before proceeding, we verify each of the proofs received to ensure everyone is behaving in an honest manner. Next, to prove that the last round of the robust semi honest MPC is computed correctly, we use another instance of the four round input delayed proof system. The first three rounds run in parallel with the first three rounds of the protocol, but the last round of the proof system is delayed till the fifth round, after computing the last round of the robust semi honest MPC. This gives the total of five rounds.

Construction. For construction of the protocol, we require the following tools:

1. A 3-round “rewinding-secure” extractable commitment scheme $\Pi_{\text{rext}} = \langle C_{\text{rext}}, R_{\text{rext}} \rangle$ (refer to definition in A.6). We require the commitments to be well formed, where this property is defined in A.6. Since there will be commitments in both directions for every pair of players, we introduce notation for individual messages of the protocol. $\pi_{\text{rext}_k \rightarrow i}^j$ refers to the j -th round of the P_k ’s commitment to P_i .

Our protocol will require both $\pi_{\text{rext}_k \rightarrow i}^j$ and $\pi_{\text{rext}_i \rightarrow k}^j$ to be sent in round j , where the latter is j -th round of P_i 's commitment to P_k . Depending on whether round j message $\pi_{\text{rext}_k \rightarrow i}^j$ is from a committer or receiver, it is sent by either P_k or P_i .

2. A 4-round robust semi honest MPC protocol Π_{rMPC} (refer to definition 1) that has a next-message function $\text{nextMsg}^{\Pi_{\text{rMPC}}}$ which, for player P_i , on input $(x_i, r_i, \vec{m}^1, \dots, \vec{m}^j)$ returns m_i^{j+1} , the message P_i broadcasts to all other players in the $(j+1)$ -th round as a part of the protocol. Here $\vec{m}^j = (m_1^j, \dots, m_n^j)$ consists of all the messages sent during round j of the protocol. The robust semi honest MPC also consists of a function $\text{Out}^{\Pi_{\text{rMPC}}}$ that computes the final output y .
3. Two 4-round delayed-input parallel non-malleable zero-knowledge protocols (refer to definition 6). We use a minor variant of the NMZK protocol in [COSV16] which is described in A.5.1. (Our proof will make non-black box use of the NMZK.)¹⁰

$\Pi_{\text{nmzk}} = \langle P_{\text{nmzk}}, V_{\text{nmzk}} \rangle$ for the language

$$L = \left\{ \left(\{ \tau_k = (\pi_{\text{rext}_i \rightarrow k}^1, \pi_{\text{rext}_i \rightarrow k}^2, \pi_{\text{rext}_i \rightarrow k}^3) \}_{k \in [n] \setminus \{i\}}, \text{id}_i, \vec{m}_{\text{rMPC}} = (\vec{m}^1, \vec{m}^2, \vec{m}^3) \right) : \right. \\ \left. \exists (x_i, r_i, \{ \text{dec}_{\text{rext}_i \rightarrow k} \}_{k \in n}) \text{ s.t. } \left((\forall k : \tau_k \text{ is a well formed commitment of } (x_i, r_i)) \text{ AND } (m_i^1 = \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i) \text{ AND } m_i^2 = \right. \right. \\ \left. \left. \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1) \text{ AND } m_i^3 = \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1, \vec{m}^2) \right) \right) \left. \right\}$$

and $\widehat{\Pi}_{\text{nmzk}} = \langle \widehat{P}_{\text{nmzk}}, \widehat{V}_{\text{nmzk}} \rangle$ for the language

$$\widehat{L} = \left\{ \left(\{ \tau_k = (\pi_{\text{rext}_i \rightarrow k}^1, \pi_{\text{rext}_i \rightarrow k}^2, \pi_{\text{rext}_i \rightarrow k}^3) \}_{k \in [n] \setminus \{i\}}, \text{id}_i, \vec{m}_{\text{rMPC}} = (\vec{m}^1, \vec{m}^2, \vec{m}^3, m_i^4) \right) : \right. \\ \left. \exists (x_i, r_i, \{ \text{dec}_{\text{rext}_i \rightarrow k} \}_{k \in n}) \text{ s.t. } \left((\forall k : \tau_k \text{ is a well formed commitment of } (x_i, r_i)) \text{ AND } (m_i^4 = \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1, \vec{m}^2, \vec{m}^3) \right) \right) \left. \right\}.$$

Similar to non-malleable commitment, we represent by $\pi_{\text{nmzk}_{k \rightarrow i}}^j$ and $\widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}^j$ the messages sent in the j -th round of P_k 's proof to P_i for an instance of L and \widehat{L} respectively.

Here L consists of instances where the player with identifier id_i , P_i , correctly computes the first 3 rounds of the robust semi honest MPC with inputs (x_i, r_i) , and commits to this input to ever other player. Likewise, \widehat{L} consists of instances where the player with identifier id_i , P_i , correctly computes the 4-th round of the robust semi honest MPC with inputs (x_i, r_i) , and commits to this input to ever other player.

Let $\mathcal{P} = \{P_1, \dots, P_n\}$ be the set of parties and $\{\text{id}_1, \dots, \text{id}_n\}$ denote their corresponding unique identifiers (one can think of $\text{id}_i = i$). The input and randomness (x_i, r_i) to the robust semi honest MPC for player P_i is fixed in the beginning of the protocol.

The protocol instructs each player P_i to compute a message M_i^j for round j and broadcasts it over the simultaneous broadcast channel. Thus in round j , messages (M_1^j, \dots, M_n^j) are simultaneously broadcast.

The protocol is detailed below. For ease of notation, we shall assume the that security parameter n is an implicit argument to each of the functions.

¹⁰We can alternatively use the original NMZK protocol in [COSV16], but we use the variant here for simplicity of exposition. We are able to do this because the witness is known in the first round.

Round 1. Each player P_i computes the message M_i^1 to be sent in the first round as follows:

1. Compute independently, with fresh randomness, the first (committer) message of the “rewinding secure” extractable commitment for every other player. i.e., $\forall k \in [n] \setminus \{i\}$

$$(\pi_{\text{rext}_{i \rightarrow k}}^1, \text{dec}_{i \rightarrow k}) \leftarrow C_{\text{rext}}((x_i, r_i))$$

$$\text{Set } \pi_{\text{rext}_i}^1 := (\pi_{\text{rext}_{i \rightarrow 1}}^1, \dots, \pi_{\text{rext}_{i \rightarrow i-1}}^1, \perp, \pi_{\text{rext}_{i \rightarrow i+1}}^1, \dots, \pi_{\text{rext}_{i \rightarrow n}}^1).$$

2. Compute independently, with fresh randomness, the first (verifier) message of both non-malleable zero-knowledge protocols for every other player. i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{nmzk}_{k \rightarrow i}}^1 \leftarrow V_{\text{nmzk}}(\mathbf{id}_k, \ell)$$

$$\widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}^1 \leftarrow \widehat{V}_{\text{nmzk}}(\mathbf{id}_k, \widehat{\ell})$$

where ℓ and $\widehat{\ell}$ are the lengths of the input delayed statements for L and \widehat{L} respectively.

Set

$$\pi_{\text{nmzk}_i}^1 := (\pi_{\text{nmzk}_{1 \rightarrow i}}^1, \dots, \pi_{\text{nmzk}_{i-1 \rightarrow i}}^1, \perp, \pi_{\text{nmzk}_{i+1 \rightarrow i}}^1, \dots, \pi_{\text{nmzk}_{n \rightarrow i}}^1)$$

$$\widehat{\pi}_{\text{nmzk}_i}^1 := (\widehat{\pi}_{\text{nmzk}_{1 \rightarrow i}}^1, \dots, \widehat{\pi}_{\text{nmzk}_{i-1 \rightarrow i}}^1, \perp, \widehat{\pi}_{\text{nmzk}_{i+1 \rightarrow i}}^1, \dots, \widehat{\pi}_{\text{nmzk}_{n \rightarrow i}}^1)$$

M_i^1 is now defined as,

$$M_i^1 := (\pi_{\text{rext}_i}^1, \pi_{\text{nmzk}_i}^1, \widehat{\pi}_{\text{nmzk}_i}^1)$$

Broadcast M_i^1 and receive $M_1^1, \dots, M_{i-1}^1, M_{i+1}^1, \dots, M_n^1$.

Round 2. Each player P_i computes the message M_i^2 to be sent in the second round as follows:

1. Compute the second message of the “rewinding secure” extractable commitment in response to the messages from the other parties. i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{rext}_{k \rightarrow i}}^2 \leftarrow R_{\text{rext}}(\pi_{\text{rext}_{k \rightarrow i}}^1)$$

where $\pi_{\text{rext}_{k \rightarrow i}}^1$ can be obtained from $\pi_{\text{rext}_k}^1$ in M_k^1 .

$$\text{Set } \pi_{\text{rext}_i}^2 := (\pi_{\text{rext}_{1 \rightarrow i}}^2, \dots, \pi_{\text{rext}_{i-1 \rightarrow i}}^2, \perp, \pi_{\text{rext}_{i+1 \rightarrow i}}^2, \dots, \pi_{\text{rext}_{n \rightarrow i}}^2).$$

2. Compute the second message of both non-malleable zero-knowledge protocols in response to the messages from the other parties. i.e., $\forall k \in [n] \setminus \{i\}$

$$w_{\text{nmzk}_i} := (x_i, r_i, \{\text{dec}_{\text{rext}_{i \rightarrow k}}\}_{k \in [n]})$$

$$\widehat{w}_{\text{nmzk}_i} := (x_i, r_i, \{\widehat{\text{dec}}_{\text{rext}_{i \rightarrow k}}\}_{k \in [n]})$$

$$\pi_{\text{nmzk}_{i \rightarrow k}}^2 \leftarrow P_{\text{nmzk}}(\mathbf{id}_i, \ell, w_{\text{nmzk}_i}, \pi_{\text{nmzk}_{i \rightarrow k}}^1)$$

$$\widehat{\pi}_{\text{nmzk}_{i \rightarrow k}}^2 \leftarrow \widehat{P}_{\text{nmzk}}(\mathbf{id}_i, \widehat{\ell}, \widehat{w}_{\text{nmzk}_i}, \widehat{\pi}_{\text{nmzk}_{i \rightarrow k}}^1)$$

where $\pi_{\text{nmzk}_{k \rightarrow i}}^1$ and $\widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}^1$ can be obtained from $\pi_{\text{nmzk}_k}^1$ and $\widehat{\pi}_{\text{nmzk}_k}^1$ respectively in M_k^1 . Set

$$\pi_{\text{nmzk}_i}^2 := (\pi_{\text{nmzk}_{i \rightarrow 1}}^2, \dots, \pi_{\text{nmzk}_{i \rightarrow i-1}}^2, \perp, \pi_{\text{nmzk}_{i \rightarrow i+1}}^2, \dots, \pi_{\text{nmzk}_{i \rightarrow n}}^2)$$

$$\widehat{\pi}_{\text{nmzk}_i}^2 := (\widehat{\pi}_{\text{nmzk}_{i \rightarrow 1}}^2, \dots, \widehat{\pi}_{\text{nmzk}_{i \rightarrow i-1}}^2, \perp, \widehat{\pi}_{\text{nmzk}_{i \rightarrow i+1}}^2, \dots, \widehat{\pi}_{\text{nmzk}_{i \rightarrow n}}^2)$$

3. Compute the first message of the robust semi honest MPC,

$$m_i^1 \leftarrow \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i).$$

M_i^2 is now defined as,

$$M_i^2 := (\pi_{\text{rext}_i}^2, \pi_{\text{nmzk}_i}^2, \widehat{\pi}_{\text{nmzk}_i}^2, m_i^1)$$

Broadcast M_i^2 and receive $M_1^2, \dots, M_{i-1}^2, M_{i+1}^2, \dots, M_n^2$.

Round 3. Each player P_i computes the message M_i^1 to be sent in the third round as follows:

1. Compute the final message of the “rewinding secure” extractable commitment. i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{rext}_{i \rightarrow k}}^3 \leftarrow C_{\text{rext}}(\pi_{\text{rext}_{i \rightarrow k}}^1, \pi_{\text{rext}_{i \rightarrow k}}^2)$$

where $\pi_{\text{rext}_{i \rightarrow k}}^1$ is as computed earlier and $\pi_{\text{rext}_{i \rightarrow k}}^2$ is obtained from $\pi_{\text{rext}_k}^2$ in M_k^2 .

Set $\pi_{\text{rext}_i}^3 := (\pi_{\text{rext}_{i \rightarrow 1}}^3, \dots, \pi_{\text{rext}_{i \rightarrow i-1}}^3, \perp, \pi_{\text{rext}_{i \rightarrow i+1}}^3, \dots, \pi_{\text{rext}_{i \rightarrow n}}^3)$.

2. Compute the third message of both non-malleable zero-knowledge protocols. i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{nmzk}_{k \rightarrow i}}^3 \leftarrow V_{\text{nmzk}}(\text{id}_k, \pi_{\text{nmzk}_{k \rightarrow i}}^1, \pi_{\text{nmzk}_{k \rightarrow i}}^2)$$

$$\widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}^3 \leftarrow \widehat{V}_{\text{nmzk}}(\text{id}_k, \widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}^1, \widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}^2)$$

where $\pi_{\text{nmzk}_{k \rightarrow i}}^1$ is as computed earlier and $\pi_{\text{nmzk}_{k \rightarrow i}}^2$ is obtained from $\pi_{\text{nmzk}_k}^2$ in M_k^2 . $\widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}^1$ and $\widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}^2$ are obtained similarly.

Set

$$\pi_{\text{nmzk}_i}^3 := (\pi_{\text{nmzk}_{1 \rightarrow i}}^3, \dots, \pi_{\text{nmzk}_{i-1 \rightarrow i}}^3, \perp, \pi_{\text{nmzk}_{i+1 \rightarrow i}}^3, \dots, \pi_{\text{nmzk}_{n \rightarrow i}}^3)$$

$$\widehat{\pi}_{\text{nmzk}_i}^3 := (\widehat{\pi}_{\text{nmzk}_{1 \rightarrow i}}^3, \dots, \widehat{\pi}_{\text{nmzk}_{i-1 \rightarrow i}}^3, \perp, \widehat{\pi}_{\text{nmzk}_{i+1 \rightarrow i}}^3, \dots, \widehat{\pi}_{\text{nmzk}_{n \rightarrow i}}^3)$$

3. Compute the second message of the robust semi honest MPC,

$$m_i^2 \leftarrow \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1)$$

where $\vec{m}^1 := (m_1^1, \dots, m_n^1)$.

M_i^3 is now defined as,

$$M_i^3 \leftarrow (\pi_{\text{rext}_i}^3, \pi_{\text{nmzk}_i}^3, \widehat{\pi}_{\text{nmzk}_i}^3, m_i^2)$$

Broadcast M_i^3 and receive $M_1^3, \dots, M_{i-1}^3, M_{i+1}^3, \dots, M_n^3$.

Round 4. Each player P_i computes the message M_i^1 to be sent in the fourth round as follows:

1. Compute the third message of the robust semi honest MPC,

$$m_i^3 \leftarrow \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1, \vec{m}^2)$$

where $\vec{m}^1 := (m_1^1, \dots, m_n^1)$ and $\vec{m}^2 := (m_1^2, \dots, m_n^2)$.

2. Set the statement and witness for the non-malleable zero-knowledge language L .

$$\forall k : \tau_k := (\pi_{\text{rext}_{i \rightarrow k}}^1, \pi_{\text{rext}_{i \rightarrow k}}^2, \pi_{\text{rext}_{i \rightarrow k}}^3)$$

$$\vec{m}_{\text{rMPC}} := (\vec{m}^1, \vec{m}^2, \vec{m}_i^3)$$

$$x_{\text{nmzk}_i} := (\{\tau_k\}_{k \in [n]}, \text{id}_i, \vec{m}_{\text{rMPC}})$$

where $|x_{\text{nmzk}_i}| = \ell$.

3. Compute the final message of the non-malleable zero-knowledge protocol for language L . i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{nmzk}_{i \rightarrow k}}^4 \leftarrow P_{\text{nmzk}}(\text{id}_i, \ell, x_{\text{nmzk}_i}, \pi_{\text{nmzk}_{i \rightarrow k}}^1, \pi_{\text{nmzk}_{i \rightarrow k}}^2, \pi_{\text{nmzk}_{i \rightarrow k}}^3)$$

where $\pi_{\text{nmzk}_{i \rightarrow k}}^1$ is obtained from $\pi_{\text{nmzk}_k}^1$ in M_k^1 . Similarly, $\pi_{\text{nmzk}_{i \rightarrow k}}^3$ is obtained from $\pi_{\text{nmzk}_k}^3$ in M_k^3 . $\pi_{\text{nmzk}_{i \rightarrow k}}^2$ is as computed earlier.

Set

$$\pi_{\text{nmzk}_i}^4 := (\pi_{\text{nmzk}_{i \rightarrow 1}}^4, \dots, \pi_{\text{nmzk}_{i \rightarrow i-1}}^4, \perp, \pi_{\text{nmzk}_{i \rightarrow i+1}}^4, \dots, \pi_{\text{nmzk}_{i \rightarrow n}}^4)$$

M_i^4 is now defined as,

$$M_i^4 := (\pi_{\text{nmzk}_i}^4, m_i^3)$$

Broadcast M_i^4 and receive $M_1^4, \dots, M_{i-1}^4, M_{i+1}^4, \dots, M_n^4$.

Round 5. Each player P_i computes the message M_i^1 to be sent in the fifth round as follows:

1. Check if all the proofs in the protocol are accepting. The proof from P_k to P_j is accepting if P_k has computed the first 3 rounds of the robust semi honest MPC correctly and has committed to the same inputs, used in the robust semi honest MPC, to every other player.

First, compute the statement x_{nmzk_k} for each player P_k . i.e., $\forall k \in [n] \setminus \{i\}$

$$\begin{aligned} \forall t : \tau_t &:= (\pi_{\text{rext}_{k \rightarrow t}}^1, \pi_{\text{rext}_{k \rightarrow t}}^2, \pi_{\text{rext}_{k \rightarrow t}}^3) \\ \vec{m}_{\text{rMPC}_k} &:= (\vec{m}^1, \vec{m}^2, \vec{m}^3_k) \\ x_{\text{nmzk}_k} &:= (\{\tau_t\}_{t \in [n]}, \text{id}_k, \vec{m}_{\text{rMPC}_k}) \end{aligned}$$

Next, check if every proof is valid.

$$\begin{aligned} \text{if } \exists k, j \text{ s.t. } \text{accept} \neq V_{\text{nmzk}}(\text{id}_k, x_{\text{nmzk}_k}, \pi_{\text{nmzk}_{k \rightarrow j}}^1, \pi_{\text{nmzk}_{k \rightarrow j}}^2, \pi_{\text{nmzk}_{k \rightarrow j}}^3, \pi_{\text{nmzk}_{k \rightarrow j}}^4) \\ \text{then output } \perp \text{ and abort} \\ \text{else continue} \end{aligned}$$

This can be done because the proofs are public coin. Moreover this is done to avoid the case that some honest parties continue on to the next round, but the others abort.

2. Compute the final message of the robust semi honest MPC,

$$m_i^4 \leftarrow \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1, \vec{m}^2, \vec{m}^3)$$

where $\vec{m}^1 := (m_1^1, \dots, m_n^1)$, $\vec{m}^2 := (m_1^2, \dots, m_n^2)$ and $\vec{m}^3 := (m_1^3, \dots, m_n^3)$.

3. Set the statement and witness for the non-malleable zero-knowledge language \hat{L} .

$$\begin{aligned} \forall k : \tau_k &:= (\pi_{\text{rext}_{i \rightarrow k}}^1, \pi_{\text{rext}_{i \rightarrow k}}^2, \pi_{\text{rext}_{i \rightarrow k}}^3) \\ \hat{m}_{\text{rMPC}_i} &:= (\vec{m}^1, \vec{m}^2, \vec{m}^3, m_i^4) \\ \hat{x}_{\text{nmzk}_i} &:= (\{\tau_k\}_{k \in [n]}, \hat{m}_{\text{rMPC}_i}, \text{id}_i) \end{aligned}$$

where $|\hat{x}_{\text{nmzk}_{i \rightarrow k}}| = \hat{\ell}$.

4. Compute the final message of the non-malleable zero-knowledge protocol for language \hat{L} . i.e., $\forall k \in [n] \setminus \{i\}$

$$\hat{\pi}_{\text{nmzk}_{i \rightarrow k}}^4 \leftarrow \hat{P}_{\text{nmzk}}(\text{id}_i, \hat{\ell}, \hat{x}_{\text{nmzk}_i}, \hat{\pi}_{\text{nmzk}_{i \rightarrow k}}^1, \hat{\pi}_{\text{nmzk}_{i \rightarrow k}}^2, \hat{\pi}_{\text{nmzk}_{i \rightarrow k}}^3)$$

where $\hat{\pi}_{\text{nmzk}_{i \rightarrow k}}^1$ is obtained from $\hat{\pi}_{\text{nmzk}_k}^1$ in M_k^1 . Similarly, $\hat{\pi}_{\text{nmzk}_{i \rightarrow k}}^3$ is obtained from $\hat{\pi}_{\text{nmzk}_k}^3$ in M_k^3 . $\hat{\pi}_{\text{nmzk}_{k \rightarrow i}}^2$ is as computed earlier.

Set $\hat{\pi}_{\text{nmzk}_i}^4 := (\hat{\pi}_{\text{nmzk}_{i \rightarrow 1}}^4, \dots, \hat{\pi}_{\text{nmzk}_{i \rightarrow i-1}}^4, \perp, \hat{\pi}_{\text{nmzk}_{i \rightarrow i+1}}^4, \dots, \hat{\pi}_{\text{nmzk}_{i \rightarrow n}}^4)$

M_i^5 is now defined as, $M_i^5 := (m_i^4, \hat{\pi}_{\text{nmzk}_i}^4)$. Broadcast M_i^5 and receive $M_1^5, \dots, M_{i-1}^5, M_{i+1}^5, \dots, M_n^5$.

Output computation. To compute the output, P_i performs the following steps:

1. Check if all the proofs in the protocol are accepting. The proof from P_k to P_j is accepting if P_k has computed the 4-th round of the robust semi honest MPC correctly and has committed to the same inputs, used in the robust semi honest MPC, to every other party.

First, compute the statement \hat{x}_{nmzk_k} for each player P_k . i.e., $\forall k \in [n] \setminus \{i\}$

$$\begin{aligned} \forall t : \tau_t &:= (\pi_{\text{rext}_{k \rightarrow t}}^1, \pi_{\text{rext}_{k \rightarrow t}}^2, \pi_{\text{rext}_{k \rightarrow t}}^3) \\ \hat{m}_{r\text{MPC}_k} &:= (\vec{m}^1, \vec{m}^2, \vec{m}^3, m_k^4) \\ \hat{x}_{\text{nmzk}_k} &:= (\{\tau_t\}_{t \in [n]}, \text{id}_k, \hat{m}_{r\text{MPC}_k}) \end{aligned}$$

Next, check if every proof is valid.

if $\exists k, j$ s.t. $\text{accept} \neq \hat{V}_{\text{nmzk}}(\text{id}_k, \hat{x}_{\text{nmzk}_k}, \hat{\pi}_{\text{nmzk}_{k \rightarrow j}}^1, \hat{\pi}_{\text{nmzk}_{k \rightarrow j}}^2, \hat{\pi}_{\text{nmzk}_{k \rightarrow j}}^3, \hat{\pi}_{\text{nmzk}_{k \rightarrow j}}^4)$
then output \perp and abort
else continue

2. Compute the output of the protocol as

$$y \leftarrow \text{Out}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1, \vec{m}^2, \vec{m}^3, \vec{m}^4)$$

Theorem 9. *Assuming security of the “rewinding secure” extractable commitment, robust semi-honest MPC and NMZK, the above described five round protocol is secure against malicious adversaries.*

Modified extractable commitments and NMZK can be instantiated from DL, while the robust semi-honest MPC can be instantiated from DDH. Thus, all the required primitives can be instantiated from DDH.

The proof can be found in appendix C.

5 Four Round Malicious MPC

Overview. We give an overview of our four round construction. At a high-level, the four round protocol is very similar to the five round protocol (from the previous section) but to compress the number of rounds we cannot have two instances of the four-round NMZK as before. Instead, we use a 3 round input-delayed strong WI argument of knowledge (with appropriate non-malleability properties), ending in the third round, to enable parties to prove their honest behavior of the first three rounds. This lets the players send the fourth message in the clear if the proof at the end of the third round verifies. For the output round, we use a four-round NMZK as before to prove honest behavior.

The three-round input-delayed proof system that we use to establish honest behavior in the first three rounds is depicted in figure 1. We do not argue its security separately, but within the hybrids of our overall security proof.

Proof for a language L using this proof system requires:

- Prover committing to a witness w using a 2-round non-malleable commitment [KS17]. The relevance of w will become clear shortly.
- The verifier sends the image of the one way permutation applied on a random string r .
- An input delayed witness indistinguishable proof of knowledge (WIPoK) proving knowledge of either
 - the decommitment of the non-malleable commitment to w such that $(x, w) \in \text{Rel}_L$; or
 - the pre-image r of the one way permutation.

Informally speaking, one can think of the above construction as a strong input delayed WI argument of knowledge with non-malleability properties.

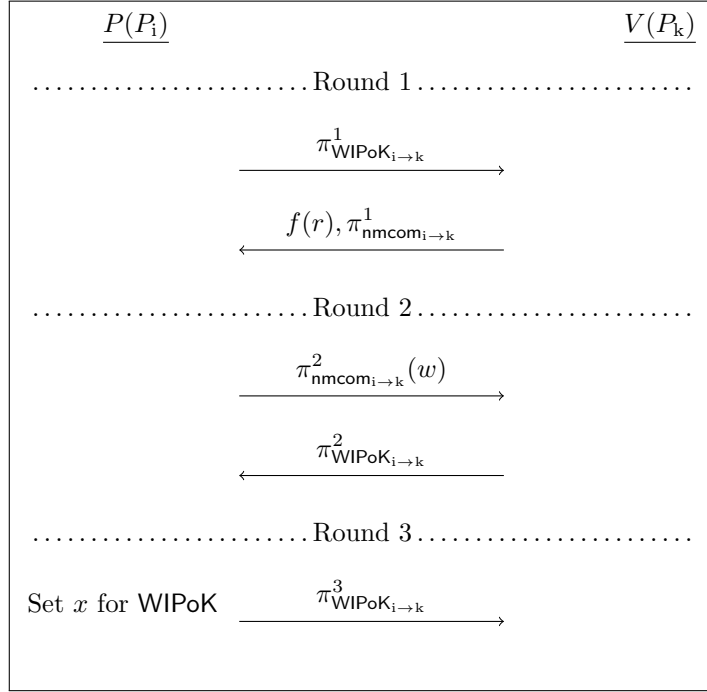

Figure 1: Components of the proof system

Construction. For construction of the protocol, we require the tools described below. The exact security levels for each of these primitives are discussed at the end of the construction.

1. A *one-way permutation* f .
2. A 3-round “rewinding secure” extractable commitment scheme $\Pi_{\text{rext}} = \langle C_{\text{rext}}, R_{\text{rext}} \rangle$ (refer to the definition in A.6).
3. An instance of a 2-round (*private coin*) extractable non-malleable commitment scheme $\Pi_{\text{nmcom}} = \langle C_{\text{nmcom}}, R_{\text{nmcom}} \rangle$ (refer to definition 5). These can be constructed from the assumption of sub-exponentially hard DDH [KS17].¹¹

We will use the following notation throughout the protocol for the various commitment schemes

$$\begin{aligned} \tau_{\text{rext}_{i \rightarrow k}} &= (\pi_{\text{rext}_{i \rightarrow k}}^1, \pi_{\text{rext}_{i \rightarrow k}}^2, \pi_{\text{rext}_{i \rightarrow k}}^3) \\ \tau_{\text{nmcom}_{i \rightarrow k}} &= (\pi_{\text{nmcom}_{i \rightarrow k}}^1, \pi_{\text{nmcom}_{i \rightarrow k}}^2) \end{aligned}$$

4. A 4-round robust semi-honest MPC protocol Π_{rMPC} as described in the five round protocol.
5. A 3 round input delayed witness indistinguishable proof of knowledge (WIPoK) protocol $\Pi_{\text{WIPoK}} = (P_{\text{WIPoK}}, V_{\text{WIPoK}})$ for the language L_{WIPoK} . We require the protocols to be public coin and instantiate them using the Lapidot-Shamir protocol [LS90].

¹¹While in all other cases, we have required the use of public coins, we can make do with a private coin protocol here. This will become apparent in the proof.

For the sake of readability and clarity, we modularize the language to obtain the final language.

$$L = \left\{ \left(\{ \tau_{\text{rext}_{i \rightarrow k}}, r_{\text{rext}_{i \rightarrow k}}^1 \}_{k \in [n] \setminus \{i\}}, \mathbf{id}_i, \vec{m}_i = (\vec{m}^1, \vec{m}^2, m_i^3) \right) : \right. \\ \left. \begin{aligned} & \exists (x_i, r_i, \{ \text{dec}_{\text{rext}_{i \rightarrow k}} \}_{k \in [n]}) \text{ s.t. } \left((\forall k : \tau_{\text{rext}_{i \rightarrow k}} \text{ is a well formed} \right. \\ & \text{commitment of } ((x_i, r_i) \oplus r_{\text{rext}_{i \rightarrow k}}^1) \text{) AND } (m_i^1 = \text{nextMsg}^{\text{PrMPC}}(x_i, r_i) \text{ AND} \\ & m_i^2 = \text{nextMsg}^{\text{PrMPC}}(x_i, r_i, \vec{m}^1) \text{ AND } m_i^3 = \\ & \left. \left. \text{nextMsg}^{\text{PrMPC}}(x_i, r_i, \vec{m}^1, \vec{m}^2) \right) \right) \end{aligned} \right\}$$

L is the language which consists of instances where player P_i correctly computes the first three rounds of the robust semi honest MPC with inputs (x_i, r_i) and commits to $(x_i, r_i) \oplus r_{\text{rext}_{i \rightarrow k}}^1$ to every other player P_k in the “rewinding secure” extractable commitment. Additionally, we require that the commitments in each of these “rewinding secure” extractable commitment is well formed. We define $x_{L_i} := (\{ \tau_{\text{rext}_{i \rightarrow k}}, r_{\text{rext}_{i \rightarrow k}}^1 \}_{k \in [n] \setminus \{i\}}, \mathbf{id}_i, \vec{m}_i = (\vec{m}^1, \vec{m}^2, m_i^3))$.

$$L_{\text{WIPoK}} = \left\{ (x_{L_i}, \mathbf{id}_k, \tau_{\text{nmcom}_{i \rightarrow k}}, y_{k \rightarrow i}) : \right. \\ \left. \begin{aligned} & \exists (w, \text{dec}_{\text{nmcom}_{i \rightarrow k}}, \rho) \text{ s.t. } \left(((x_{L_i}, w) \in \text{Rel}_L \text{) AND} \right. \\ & \left. ((w, \text{dec}_{\text{nmcom}_{i \rightarrow k}}, \mathbf{id}_i) \text{ is a valid decommitment of } \tau_{\text{nmcom}_{i \rightarrow k}} \text{)} \right) \\ & \text{OR } f(\rho) = y_{k \rightarrow i} \end{aligned} \right\}$$

L_{WIPoK} consists of instances where player P_i proves to player P_k that either

- it behaved honestly, i.e. it has a witness w such that $(x_{L_i}, w) \in \text{Rel}_L$, and it has committed to this w in the non-malleable commitment; or
- it possesses the trapdoor mentioned earlier.

We define $x_{\text{WIPoK}_{i \rightarrow k}} := (x_{L_i}, \mathbf{id}_k, \tau_{\text{nmcom}_{i \rightarrow k}}, y_{k \rightarrow i})$.

6. A 4-round delayed-input parallel non-malleable zero-knowledge protocols (refer to definition 6). We use the NMZK protocol in [COSV16] which is described in A.5.1. Our proof will make non-black box use of the NMZK.

$\Pi_{\text{nmzk}} = \langle P_{\text{nmzk}}, V_{\text{nmzk}} \rangle$ for the language

$$\widehat{L} = \left\{ \left(\{ \tau_{\text{rext}_{i \rightarrow k}}, r_{\text{rext}_{i \rightarrow k}}^1 \}_{k \in [n] \setminus \{i\}}, \mathbf{id}_i, \vec{m}_i = (\vec{m}^1, \vec{m}^2, \vec{m}^3, m_i^4) \right) : \right. \\ \left. \begin{aligned} & \exists (x_i, r_i, \{ \text{dec}_{\text{rext}_{i \rightarrow k}} \}_{k \in [n]}) \text{ s.t. } \left((\forall k : \tau_{\text{rext}_{i \rightarrow k}} \text{ is a well formed} \right. \\ & \text{commitment of } ((x_i, r_i) \oplus r_{\text{rext}_{i \rightarrow k}}^1) \text{) AND} \\ & \left. \left. (m_i^4 = \text{nextMsg}^{\text{PrMPC}}(x_i, r_i, \vec{m}^1, \vec{m}^2, \vec{m}^3) \right) \right) \end{aligned} \right\}.$$

\widehat{L} is the language which consists of instances where player P_i (a) correctly computed the final round of the robust MPC with inputs (x_i, r_i) ; and (b) commits to $(x_i, r_i) \oplus r_{\text{rext}_{i \rightarrow k}}^1$ to every other player P_k in the “rewinding secure” extractable commitment such that they are well formed. We define $\widehat{x}_{L_i} := (\{ \tau_{\text{rext}_{i \rightarrow k}}, r_{\text{rext}_{i \rightarrow k}}^1 \}_{k \in [n] \setminus \{i\}}, \mathbf{id}_i, \vec{m}_i = (\vec{m}^1, \vec{m}^2, \vec{m}^3, m_i^4))$.

Round 1. Each player P_i computes the message M_i^1 to be sent in the first round as follows:

1. Compute independently, with fresh randomness, the first (committer) message of the “rewinding secure” extractable commitment for every other player. i.e., $\forall k \in [n] \setminus \{i\}$

$$\begin{aligned} r_{\text{rext}_{i \rightarrow k}}^0 &\leftarrow \{0, 1\}^{|(x_i, r_i)|} \\ (\pi_{\text{rext}_{i \rightarrow k}}^1, \text{dec}_{i \rightarrow k}) &\leftarrow C_{\text{rext}}(r_{\text{rext}_{i \rightarrow k}}^0) \end{aligned}$$

Set

$$\pi_{\text{rext}_i}^1 := (\pi_{\text{rext}_{i \rightarrow 1}}^1, \dots, \pi_{\text{rext}_{i \rightarrow i-1}}^1, \perp, \pi_{\text{rext}_{i \rightarrow i+1}}^1, \dots, \pi_{\text{rext}_{i \rightarrow n}}^1).$$

2. Compute the first message of the robust semi honest MPC,

$$m_i^1 \leftarrow \text{nextMsg}^{\Pi_{\text{MPC}}}(x_i, r_i)$$

3. Compute the different components that will make up the proof system for L .

- (a) Select a random strings independently that will serve as the basis for the trapdoor, and apply the function f to send to every other player. i.e., $\forall k \in [n] \setminus \{i\}$

$$\begin{aligned} \rho_{i \rightarrow k} &\leftarrow \{0, 1\}^{\text{poly}(n)} \\ y_{i \rightarrow k} &:= f(\rho_{i \rightarrow k}) \end{aligned}$$

Set

$$y_i := (y_{i \rightarrow 1}, \dots, y_{i \rightarrow i-1}, \perp, y_{i \rightarrow i+1}, \dots, y_{i \rightarrow n}).$$

- (b) Commit to the first (receiver) message of the non-malleable commitment to every other player. i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{nmcom}_{k \rightarrow i}}^1 \leftarrow R_{\text{nmcom}}(1^n)$$

Set

$$\pi_{\text{nmcom}_i}^1 := (\pi_{\text{nmcom}_{1 \rightarrow i}}^1, \dots, \pi_{\text{nmcom}_{i-1 \rightarrow i}}^1, \perp, \pi_{\text{nmcom}_{i+1 \rightarrow i}}^1, \dots, \pi_{\text{nmcom}_{n \rightarrow i}}^1).$$

- (c) Compute the first message for the input delayed witness indistinguishable proof of knowledge (WIPoK) for L_{WIPoK} to every other player. i.e. $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{WIPoK}_{i \rightarrow k}}^1 \leftarrow P_{\text{WIPoK}}(\ell)$$

where ℓ is the size of the statement.

Set

$$\pi_{\text{WIPoK}_i}^1 := (\pi_{\text{WIPoK}_{i \rightarrow 1}}^1, \dots, \pi_{\text{WIPoK}_{i \rightarrow i-1}}^1, \perp, \pi_{\text{WIPoK}_{i \rightarrow i+1}}^1, \dots, \pi_{\text{WIPoK}_{i \rightarrow n}}^1).$$

4. Compute independently, with fresh randomness, the first (verifier) message of the non-malleable zero-knowledge protocol for every other player. i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{nmzk}_{k \rightarrow i}}^1 \leftarrow V_{\text{nmzk}}(\text{id}_k, \widehat{\ell})$$

where $\widehat{\ell}$ is the length of the input delayed statement for \widehat{L} .

Set

$$\pi_{\text{nmzk}_i}^1 := (\pi_{\text{nmzk}_{1 \rightarrow i}}^1, \dots, \pi_{\text{nmzk}_{i-1 \rightarrow i}}^1, \perp, \pi_{\text{nmzk}_{i+1 \rightarrow i}}^1, \dots, \pi_{\text{nmzk}_{n \rightarrow i}}^1)$$

M_i^1 is now defined as,

$$M_i^1 := (\pi_{\text{rext}_i}^1, y_i, \pi_{\text{WIPoK}_i}^1, \pi_{\text{nmcom}_i}^1, \pi_{\text{nmzk}_i}^1, m_i^1)$$

Broadcast M_i^1 and receive $M_1^1, \dots, M_{i-1}^1, M_{i+1}^1, \dots, M_n^1$.

Round 2. Each player P_i computes the message M_i^2 to be sent in the second round as follows:

1. Compute the second message of the “rewinding secure” extractable commitment in response to the messages from the other parties. i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{rext}_{k \rightarrow i}}^2 \leftarrow R_{\text{rext}}(\pi_{\text{rext}_{k \rightarrow i}}^1)$$

where $\pi_{\text{rext}_{k \rightarrow i}}^1$ can be obtained from $\pi_{\text{rext}_k}^1$ in M_k^1 .

Set

$$\pi_{\text{rext}_i}^2 := (\pi_{\text{rext}_{1 \rightarrow i}}^2, \dots, \pi_{\text{rext}_{i-1 \rightarrow i}}^2, \perp, \pi_{\text{rext}_{i+1 \rightarrow i}}^2, \dots, \pi_{\text{rext}_n \rightarrow i}^2).$$

2. Compute the second message of the robust semi honest MPC,

$$m_i^2 \leftarrow \text{nextMsg}^{\text{IIrMPC}}(x_i, r_i, \vec{m}^1)$$

where $\vec{m}^1 := (m_1^1, \dots, m_n^1)$.

3. Compute the second message for the different components in the proof system for L .

- (a) Compute the second message of the non-malleable commitment scheme in response to the messages from the other parties. Here, we shall commit to the witness i.e. $\forall k \in [n] \setminus \{i\}$

$$w := (x_i, r_i, \{\text{dec}_{\text{rext}_{i \rightarrow k}}\}_{k \in [n]})$$

$$(\pi_{\text{nmcom}_{i \rightarrow k}}^1, \text{dec}_{\text{nmcom}_{i \rightarrow k}}) \leftarrow C_{\text{nmcom}}(w, \pi_{\text{nmcom}_{i \rightarrow k}}^1)$$

where $\pi_{\text{nmcom}_{i \rightarrow k}}^1$ can be obtained from $\pi_{\text{nmcom}_k}^1$ in M_k^1 .

Set

$$\pi_{\text{nmcom}_i}^2 := (\pi_{\text{nmcom}_{i \rightarrow 1}}^2, \dots, \pi_{\text{nmcom}_{i \rightarrow i-1}}^2, \perp, \pi_{\text{nmcom}_{i \rightarrow i+1}}^2, \dots, \pi_{\text{nmcom}_{i \rightarrow n}}^2).$$

- (b) Compute the second message of the input delayed WIPoK for L_{WIPoK} in response to messages from every other player. i.e. $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{WIPoK}_{k \rightarrow i}}^2 \leftarrow V_{\text{WIPoK}}(\ell, \pi_{\text{WIPoK}_{k \rightarrow i}}^1)$$

where $\pi_{\text{WIPoK}_{k \rightarrow i}}^1$ can be obtained from $\pi_{\text{WIPoK}_k}^1$ in M_k^1 .

Set $\pi_{\text{WIPoK}_i}^1 := (\pi_{\text{WIPoK}_{1 \rightarrow i}}^1, \dots, \pi_{\text{WIPoK}_{i-1 \rightarrow i}}^1, \perp, \pi_{\text{WIPoK}_{i+1 \rightarrow i}}^1, \dots, \pi_{\text{WIPoK}_{n \rightarrow i}}^1)$.

4. Compute the second message of the non-malleable zero-knowledge protocols in response to the messages from the other parties. i.e., $\forall k \in [n] \setminus \{i\}$

$$w_{\text{nmzk}_i} := (x_i, r_i, \{\text{dec}_{\text{rext}_{i \rightarrow k}}\}_{k \in [n]})$$

$$\pi_{\text{nmzk}_{i \rightarrow k}}^2 \leftarrow P_{\text{nmzk}}(\text{id}_i, \hat{\ell}, w_{\text{nmzk}_i}, \pi_{\text{nmzk}_{i \rightarrow k}}^1)$$

where $\pi_{\text{nmzk}_{k \rightarrow i}}^1$ can be obtained from $\pi_{\text{nmzk}_k}^1$ in M_k^1 . Set

$$\pi_{\text{nmzk}_i}^2 := (\pi_{\text{nmzk}_{i \rightarrow 1}}^2, \dots, \pi_{\text{nmzk}_{i \rightarrow i-1}}^2, \perp, \pi_{\text{nmzk}_{i \rightarrow i+1}}^2, \dots, \pi_{\text{nmzk}_{i \rightarrow n}}^2)$$

M_i^2 is now defined as, $M_i^2 := (\pi_{\text{rext}_i}^2, \pi_{\text{nmcom}_i}^2, \pi_{\text{WIPoK}_i}^2, \pi_{\text{nmzk}_i}^2, m_i^2)$. Broadcast M_i^2 and receive $M_1^2, \dots, M_{i-1}^2, M_{i+1}^2, \dots,$

Round 3. Each player P_i computes the message M_i^1 to be sent in the third round as follows:

1. Compute the final message of the “rewinding secure” extractable commitment. i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{rext}_{i \rightarrow k}}^3 \leftarrow C_{\text{rext}}(\pi_{\text{rext}_{i \rightarrow k}}^1, \pi_{\text{rext}_{i \rightarrow k}}^2)$$

where $\pi_{\text{rext}_{i \rightarrow k}}^1$ is as computed earlier and $\pi_{\text{rext}_{i \rightarrow k}}^2$ is obtained from $\pi_{\text{rext}_k}^2$ in M_k^2 .

Set $\pi_{\text{rext}_i}^3 := (\pi_{\text{rext}_{i \rightarrow 1}}^3, \dots, \pi_{\text{rext}_{i \rightarrow i-1}}^3, \perp, \pi_{\text{rext}_{i \rightarrow i+1}}^3, \dots, \pi_{\text{rext}_{i \rightarrow n}}^3)$.

2. Compute (x_i, r_i) masked with the randomness sent in the “rewinding secure” extractable commitment, i.e. $\forall k \in [n] \setminus \{i\}$

$$r_{\text{rext}_{i \rightarrow k}}^1 := r_{\text{rext}_{i \rightarrow k}}^0 \oplus (x_i, r_i)$$

Set $r_{\text{rext}_i}^1 := (r_{\text{rext}_{i \rightarrow 1}}^1, \dots, r_{\text{rext}_{i \rightarrow i-1}}^1, \perp, r_{\text{rext}_{i \rightarrow i+1}}^1, \dots, r_{\text{rext}_{i \rightarrow n}}^1)$.

3. Compute the third message of the robust semi honest MPC,

$$m_i^3 \leftarrow \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1, \vec{m}^2)$$

where $\vec{m}^1 := (m_1^1, \dots, m_n^1)$ and $\vec{m}^2 := (m_1^2, \dots, m_n^2)$.

4. Compute the third message for the different components in the proof system for L .

(a) Set the statement and witness for the input delayed WIPoK language L_{WIPoK} .

$$\vec{m} := (\vec{m}^1, \vec{m}^2, m_i^3)$$

$$x_{L_i} := \left(\left\{ \tau_{\text{rext}_{i \rightarrow k}}, r_{\text{rext}_{i \rightarrow k}}^1 \right\}_{k \in [n]}, \text{id}_i, \vec{m} \right)$$

$$w_{L_i} := (x_i, r_i, \left\{ \text{dec}_{\text{rext}_{i \rightarrow k}} \right\}_{k \in [n]})$$

$$\forall k : x_{\text{WIPoK}_{i \rightarrow k}} := (x_{L_i}, \text{id}_k, \tau_{\text{nmcom}_{i \rightarrow k}}, y_{k \rightarrow i})$$

$$\forall k : w_{\text{WIPoK}_{i \rightarrow k}} := (w_{L_i}, \text{dec}_{\text{nmcom}_{i \rightarrow k}}, \perp)$$

where $\forall k : |x_{\text{WIPoK}_{i \rightarrow k}}| = \ell$.

Compute the final message of the WIPoK for language L_{WIPoK} , i.e. $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{WIPoK}_{i \rightarrow k}}^3 \leftarrow F_{\text{WIPoK}}(x_{\text{WIPoK}_{i \rightarrow k}}, w_{\text{WIPoK}_{i \rightarrow k}}, \pi_{\text{WIPoK}_{i \rightarrow k}}^1, \pi_{\text{WIPoK}_{i \rightarrow k}}^2)$$

Set $\pi_{\text{WIPoK}_i}^3 := (\pi_{\text{WIPoK}_{i \rightarrow 1}}^3, \dots, \pi_{\text{WIPoK}_{i \rightarrow i-1}}^3, \perp, \pi_{\text{WIPoK}_{i \rightarrow i+1}}^3, \dots, \pi_{\text{WIPoK}_{i \rightarrow n}}^3)$.

5. Compute the third message of the non-malleable zero-knowledge protocol. i.e., $\forall k \in [n] \setminus \{i\}$

$$\pi_{\text{nmzk}_{k \rightarrow i}}^3 \leftarrow V_{\text{nmzk}}(\text{id}_k, \pi_{\text{nmzk}_{k \rightarrow i}}^1, \pi_{\text{nmzk}_{k \rightarrow i}}^2)$$

where $\pi_{\text{nmzk}_{k \rightarrow i}}^1$ is as computed earlier and $\pi_{\text{nmzk}_{k \rightarrow i}}^2$ is obtained from $\pi_{\text{nmzk}_k}^2$ in M_k^2 .

Set

$$\pi_{\text{nmzk}_i}^3 := (\pi_{\text{nmzk}_{1 \rightarrow i}}^3, \dots, \pi_{\text{nmzk}_{i-1 \rightarrow i}}^3, \perp, \pi_{\text{nmzk}_{i+1 \rightarrow i}}^3, \dots, \pi_{\text{nmzk}_{n \rightarrow i}}^3)$$

M_i^3 is now defined as, $M_i^3 := (\pi_{\text{rext}_i}^3, r_{\text{rext}_i}^1, \pi_{\text{WIPoK}_i}^3, \pi_{\text{nmzk}_i}^3, m_i^3)$. Broadcast M_i^3 and receive $M_1^3, \dots, M_{i-1}^3, M_{i+1}^3, \dots, M_n^3$.

Round 4. Each player P_i computes the message M_i^1 to be sent in the fourth round as follows:

1. Check if all the proofs in the protocol L_{WIPoK} are accepting. Compute, as earlier, the statement $x_{\text{WIPoK}_{k \rightarrow j}}$ for every player P_k and P_j .

Next, check if every proof is valid.

if $\exists k, j$ s.t $\text{accept} \neq V_{\text{WIPoK}}(x_{\text{WIPoK}_{k \rightarrow j}}, \pi_{\text{WIPoK}_{k \rightarrow j}}^1, \pi_{\text{WIPoK}_{k \rightarrow j}}^2, \pi_{\text{WIPoK}_{k \rightarrow j}}^3)$
then output \perp and abort
else continue

2. Compute the final message of the robust semi honest MPC,

$$m_i^4 \leftarrow \text{nextMsg}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1, \vec{m}^2, \vec{m}^3)$$

where $\vec{m}^1 := (m_1^1, \dots, m_n^1)$, $\vec{m}^2 := (m_1^2, \dots, m_n^2)$ and $\vec{m}^3 := (m_1^3, \dots, m_n^3)$.

3. Compute the final message of the non-malleable zero-knowledge protocol for language \widehat{L} . i.e., $\forall k \in [n] \setminus \{i\}$

$$\vec{m}_i := (\vec{m}^1, \vec{m}^2, \vec{m}^3, m_i^4)$$

$$x_{\widehat{L}_i} := \left(\left\{ \tau_{\text{rext}_{i \rightarrow k}}, r_{\text{rext}_{i \rightarrow k}}^1 \right\}_{k \in [n]}, \text{id}_i, \vec{m}_i \right)$$

$$\pi_{\text{nmzk}_{i \rightarrow k}}^4 \leftarrow P_{\text{nmzk}}(\text{id}_i, \widehat{\ell}, x_{\widehat{L}_i}, \pi_{\text{nmzk}_{i \rightarrow k}}^1, \pi_{\text{nmzk}_{i \rightarrow k}}^2, \pi_{\text{nmzk}_{i \rightarrow k}}^3)$$

where $\pi_{\text{nmzk}_{i \rightarrow k}}^1$ is obtained from $\pi_{\text{nmzk}_k}^1$ in M_k^1 . Similarly, $\pi_{\text{nmzk}_{i \rightarrow k}}^3$ is obtained from $\pi_{\text{nmzk}_k}^3$ in M_k^3 . $\pi_{\text{nmzk}_{i \rightarrow k}}^2$ is as computed earlier.

Set

$$\pi_{\text{nmzk}_i}^4 := (\pi_{\text{nmzk}_{i \rightarrow 1}}^4, \dots, \pi_{\text{nmzk}_{i \rightarrow i-1}}^4, \perp, \pi_{\text{nmzk}_{i \rightarrow i+1}}^4, \dots, \pi_{\text{nmzk}_{i \rightarrow n}}^4)$$

M_i^4 is now defined as, $M_i^4 := (m_i^4, \pi_{\text{nmzk}_i}^4)$. Broadcast M_i^4 and receive $M_1^4, \dots, M_{i-1}^4, M_{i+1}^4, \dots, M_n^4$.

Output Computation. To compute the output, P_i performs the following steps:

1. Check if all the proofs in the protocol for $\widehat{L}_{\text{WIPoK}}$ are accepting. As before, compute the statement $\widehat{x}_{\text{WIPoK}_{k \rightarrow j}}$ for each player P_k and P_j .

Next, check if every proof is valid.

if $\exists k, j$ s.t $\text{accept} \neq \widehat{V}_{\text{WIPoK}}(\widehat{x}_{\text{WIPoK}_{k \rightarrow j}}, \widehat{\pi}_{\text{WIPoK}_{k \rightarrow j}}^1, \widehat{\pi}_{\text{WIPoK}_{k \rightarrow j}}^2, \widehat{\pi}_{\text{WIPoK}_{k \rightarrow j}}^3)$
then output \perp and abort
else continue

2. Compute the output of the protocol as

$$y \leftarrow \text{Out}^{\Pi_{\text{rMPC}}}(x_i, r_i, \vec{m}^1, \vec{m}^2, \vec{m}^3, \vec{m}^4)$$

This completes the description of the protocol.

We require the following security levels for the primitives used in our construction, which are achieved by setting parameters accordingly:

- $T_{\text{rMPC}_{(1-3)}}, T_{\text{WIPoK}} \gg T_{\text{rext}}, T_{\text{Sign}}$.
- $T_{\text{rMPC}_{(1-3)}} \gg T_{\text{nmcom}}$.
- $T_{\text{nmcom}} \gg T_f$.
- $T_{\text{rext}} \gg T_f$.

where T_{prim} means that the primitive **prim** is secure against adversaries running in time T_{prim} , and $T \ll T'$ means that $T \cdot \text{poly}(n) < T'$. Here **nmcom** is with respect to the two-round non-malleable commitment. $T_{\text{rMPC}_{(1-3)}}$ means that we require the first three rounds of our robust MPC to be indistinguishable (for adversaries running in time $T_{\text{rMPC}_{(1-3)}}$) for any two sets of inputs and randomnesses. In fact, in our construction, the simulator Sim^1 works by setting a random input to generate the first three rounds. Hence, for our construction, we require $T_{\text{rMPC}_{(1-3)}}$ -security for the following two distributions: $\text{RealExec}_{(t-1)}^{A^1}(\vec{x}, z)$ and $\text{Sim}^1(z)$.

Theorem 10. *Assuming one-way permutations, T_{WIPoK} -security of the input delayed WIPoK, T_{nmcom} -security of the two round non-malleable commitment, T_{rext} -security of the “rewinding secure” extractable commitment, $T_{\text{rMPC}_{(1-3)}}$ -security of the first three rounds of the robust semi-honest MPC, and security of the NMZK, the described four round protocol is secure against malicious adversaries.*

All the primitives above with the desired security levels can be instantiated from sub-exponential DDH.

The proof of the above theorem can be found in appendix D.

6 Acknowledgements

The third author would like to thank Yuval Ishai for suggesting ideas for constructing a four-round semi-honest MPC protocol using randomizing polynomials. They form the core of our robust semi-honest MPC protocol.

The first author was supported by grant 360584 from the Simons Foundation. The second and the third authors were supported in part by a DARPA/ARL Safeware Grant W911NF-15-C-0213.

A Definitions

We denote n to be the security parameter. Consider two distributions \mathcal{D}_0 and \mathcal{D}_1 . We denote $\mathcal{D}_0 \approx_c \mathcal{D}_1$ if \mathcal{D}_0 and \mathcal{D}_1 are computationally indistinguishable.

A.1 Oblivious Transfer

We recall the notion of oblivious transfer [Rab05, EGL82] below. We require that the oblivious transfer protocol satisfies *covert security* [vHL05, CGOS07, GJ10]. Intuitively, we require that the receiver’s messages are computationally indistinguishable from a uniform distribution to a malicious sender. Similarly,

we require that the sender's messages are computationally indistinguishable from a uniform distribution to a malicious receiver.

Definition 2 (Covert Oblivious Transfer). *A 1-out-of-2 oblivious transfer (OT) protocol OT is a two party protocol between a sender and a receiver. A sender has two input bits (b_0, b_1) and the receiver has a choice bit c . At the end of the protocol, the receiver receives an output bit b' . We denote this process by $b' \leftarrow \langle \text{Sen}(b_0, b_1), \text{Rec}(c) \rangle$.*

We require that an OT protocol satisfies the following properties:

- **Correctness:** *For every $b_0, b_1, c \in \{0, 1\}$, we have:*

$$\Pr[b_c \leftarrow \langle \text{Sen}(b_0, b_1), \text{Rec}(c) \rangle] = 1$$

- **Covert security against adversarial senders:** *For all PPT senders Sen^* , we require that the honest receiver's messages are computationally indistinguishable from uniform distribution.*
- **Covert security against adversarial receivers:** *Suppose the input of the sender (b_0, b_1) is sampled from a distribution on $\{0, 1\}^2$. For all PPT receivers Rec^* , we require that the honest sender's messages (computed as a function of (b_0, b_1)) are computationally indistinguishable.*

An oblivious transfer protocol satisfying the above definition was constructed in [vHL05] using [NP01].

Theorem 11 ([vHL05]). *Assuming decisional Diffie Helman assumption, there exists a two message 1-out-of-2 covert oblivious transfer protocol.*

A.2 Randomizing Polynomials

We first recall the definition of randomizing polynomials [IK00, AIK06]. Instead of considering the standard form of randomizing polynomials consisting of encode and decode algorithms, we instead consider a decomposable version where the circuit is first encoded as polynomials and decode algorithm gets as input evaluations of polynomials on input and randomness.

Definition 3 (Randomizing Polynomials). *A randomizing polynomials scheme $\text{RP} = (\text{CktE}, \text{D})$ for a family of circuits \mathcal{C} has the following syntax:*

- *Encoding, $\text{CktE}(C)$: On input circuit $C \in \mathcal{C}$, input x , it outputs polynomials p_1, \dots, p_m .*
- *Decoding, $\text{D}(p_1(x; r), \dots, p_m(x; r))$: On input evaluations of polynomials $p_1(x; r), \dots, p_m(x; r)$, it outputs the decoded value α .*

RP is required to satisfy the following properties:

- **Correctness:** *For every security parameter $n \in \mathbb{N}$, circuit C and input x , $C(x) = \text{D}(p_1(x; r), \dots, p_m(x; r))$, where (i) $(p_1, \dots, p_m) \leftarrow \text{CktE}(C)$, (ii) r is randomness sampled from uniform distribution.*
- **Efficiency:** *The typical efficiency we require is that the degree of the polynomials $\{p_i\}$ should be significantly smaller than the degree of the circuit C , where $(p_1, \dots, p_m) \leftarrow \text{CktE}(C)$.*
- **Security:** *For every PPT adversary \mathcal{A} , for large enough security parameter $n \in \mathbb{N}$, circuit C and input x , there exists a simulator Sim such that:*

$$\{(p_1(x; r), \dots, p_m(x; r))\} \approx_c \left\{ \text{Sim}(1^n, 1^{|C|}, C(x)) \right\},$$

where (i) $(p_1, \dots, p_m) \leftarrow \text{CktE}(C)$, (ii) r is randomness sampled from uniform distribution.

We define the **degree** of randomizing polynomials to be $\max_{C \in \mathcal{C}} \{\deg(p_i) : (p_1, \dots, p_m) \leftarrow \text{CktE}(C \in \mathcal{C})\}$.

We have the following theorem from [AIK06].

Theorem 12 ([AIK06]). *Assuming the existence of pseudorandom generators in $\oplus\text{L}/\text{Poly}$, there exists a degree 3 randomizing polynomials for \mathcal{C} .*

A.3 Secure Multi-Party Computation

A secure multi-party computation protocol is a protocol executed by n number of parties P_1, \dots, P_n for a n -party functionality F . We allow for parties to exchange messages simultaneously. In every round, every party is allowed to broadcast messages to all parties. A protocol is said to have k rounds if the number of rounds in the protocol is k . We require that at the end of the protocol, all the parties receive the output¹² $F(x_1, \dots, x_n)$, where x_i is the i^{th} party's input. We formalize the security notion below.

Ideal World. We start by describing the ideal world experiment where n parties P_1, \dots, P_n interact with an ideal functionality for computing a function F . An adversary may corrupt any subset $\mathcal{P}^A \subset \mathcal{P}$ of the parties. We denote the honest parties by \mathcal{H} .

Inputs: Each party P_i obtains an initial input x_i . The adversary Sim is given auxiliary input z . Sim selects a subset of the parties $\mathcal{P}^A \subset \mathcal{P}$ to corrupt, and is given the inputs x_k of each party $P_k \in \mathcal{P}^A$.

Sending inputs to trusted party: Each honest party P_i sends its input x_i to the trusted party. For each corrupted party $P_i \in \mathcal{P}^A$, the adversary may select any value x_i^* and send it to the ideal functionality.

Trusted party computes output: Let x_1^*, \dots, x_n^* be the inputs that were sent to the trusted party. The trusted party sends $F(x_1^*, \dots, x_n^*)$ to the adversary who replies with either **continue** or **abort**. If the adversary's message is **abort**, then the trusted party sends \perp to all honest parties. Otherwise, it sends the function evaluation $F(x_1^*, \dots, x_n^*)$ to all honest parties.

Outputs: Honest parties output all the messages they obtained from the ideal functionality. Malicious parties may output an arbitrary PPT function of the adversary's view.

The overall output of the ideal-world experiment consists of the outputs of all parties. For any ideal-world adversary Sim with auxiliary input $z \in \{0, 1\}^*$, input vector \vec{x} , and security parameter n , we denote the output of the corresponding ideal-world experiment by

$$\text{IDEAL}_{\text{Sim}, F}(1^n, \vec{x}, z).$$

Real World. The real world execution begins by an adversary \mathcal{A} selecting any arbitrary subset of parties $\mathcal{P}^A \subset \mathcal{P}$ to corrupt. The parties then engage in an execution of a real n -party protocol Π . Throughout the execution of Π , the adversary \mathcal{A} sends all messages on behalf of the corrupted parties, and may follow an arbitrary polynomial-time strategy. In contrast, the honest parties follow the instructions of Π .

At the conclusion of all the update phases, each honest party P_i outputs all the outputs it obtained in the computations. Malicious parties may output an arbitrary PPT function of the view of \mathcal{A} .

For any adversary \mathcal{A} with auxiliary input $z \in \{0, 1\}^*$, input vector \vec{x} , and security parameter n , we denote the output of the MPC protocol Π by

$$\text{REAL}_{\mathcal{A}, \Pi}(1^n, \vec{x}, z).$$

Security Definition. We say that a protocol Π is a secure protocol if any adversary, who corrupts a subset of parties and runs the protocol with honest parties, gains *no information* about the inputs of the honest parties beyond the protocol output.

¹²We can also consider asymmetric functionalities where every party receives a different output. We don't discuss this in our work.

Definition 4. A protocol Π is a secure n -party protocol computing F if for every PPT adversary \mathcal{A} in the real world, there exists a PPT adversary Sim corrupting the same parties in the ideal world such that for every initial input vector \vec{x} , every auxiliary input z , it holds that

$$\text{IDEAL}_{\text{Sim},F}(1^n, \vec{x}, z) \approx_c \text{REAL}_{\mathcal{A},\Pi}(1^n, \vec{x}, z).$$

A.4 Non-malleable Commitments

Let $\Pi = \langle C, R \rangle$ be a statistically binding commitment scheme. Consider MiM adversaries that are participating in one left and one right sessions in which k commitments take place. We compare between a MiM and a simulated execution. In the MiM execution, the adversary \mathcal{A} , with auxiliary information z , is participating in one left and one right sessions. In the left sessions the MiM adversary interacts with C receiving commitments to value m using identities id of its choice. In the right session \mathcal{A} interacts with R , attempting to commit to a related value \tilde{m} again using identities $\tilde{\text{id}}$ of its choice. If any the right commitment is invalid, or undefined, its value is set to \perp . If $\tilde{\text{id}} = \text{id}$, set $\tilde{m} = \perp$ (i.e., any commitment where the adversary uses the same identity as that of honest senders is considered invalid). Let

$$\text{mim}_{\Pi}^{\mathcal{A},m}(z)$$

denote the random variable that describes the values \tilde{m} and the view of \mathcal{A} , in the above experiment.

In the simulated execution, an efficient simulator Sim directly interacts with R . Let

$$\text{sim}_{\Pi}^{\text{Sim}}(1^n, z)$$

denote the random variable describing the value \tilde{m} committed by Sim , and the output view of Sim ; whenever the view contains the same identity as that identity of the left session, \tilde{m} is set to \perp .

Definition 5 (non-malleable commitment scheme). A commitment scheme is non-malleable with respect to commitment if, for every PPT parallel MiM adversary \mathcal{A} , there exists a PPT simulator Sim such that for all m the following ensembles are computationally indistinguishable:

$$\{\text{mim}_{\Pi}^{\mathcal{A},m}(z)\}_{n \in \mathbb{N}, z \in \{0,1\}^*} \approx \{\text{sim}_{\Pi}^{\text{Sim}}(1^n, z)\}_{n \in \mathbb{N}, z \in \{0,1\}^*}$$

For our construction, we will require that the non-malleable commitments are public coin and extractable. Four round non-malleable commitments based on CRHFs satisfying both the conditions are described in [GRRV14]. Similarly, three round non-malleable commitments based on quasi-polynomial injective OWFs satisfying both conditions are described in [GPR16]. Two round (private coin) non-malleable commitments are based on sub-exponential hardness of DDH[KS17].

Binding property of the commitments. For convenience, we assume that the first message sent by the committer in the four round non-malleable commitment scheme is statistically binding. Thus, the second message in the scheme is statistically binding. The non-malleable commitment scheme in [COSV16] satisfies this property. But importantly, with minor modifications our proofs go through even without this assumption.

A.5 Delayed-input Non-malleable Zero Knowledge

Let $\Pi_{\text{nmzk}} = \langle P, V \rangle$ be a delayed-input interactive argument system for an NP-language L with witness relation Rel_L . Consider a PPT MiM adversary \mathcal{A} that is simultaneously participating in one left session and one right session. Before the execution starts, both P , V and \mathcal{A} receive as a common input the security parameter n , and \mathcal{A} receives as auxiliary input $z \in \{0,1\}^*$.

In the left session \mathcal{A} interacts with P using identity id of his choice. In the right session, \mathcal{A} interacts with V , using identity $\tilde{\text{id}}$ of his choice.

In the left session, before the last round of the protocol, P gets the statement x . Also, in the right session \mathcal{A} , during the last round of the protocol selects the statement \tilde{x} to be proved and sends it to V . Let $\text{View}^{\mathcal{A}}(1^n, z)$ denote a random variable that describes the view of \mathcal{A} in the above experiment.

Definition 6 (Delayed-input NMZK). *A delayed-input argument system*

$\Pi_{\text{nmzk}} = \langle P, V \rangle$ for NP-language L with witness relation Rel_L is Non-Malleable Zero Knowledge (NMZK) if for any MiM adversary \mathcal{A} that participates in one left session and one right session, there exists a PPT machine $\text{Sim}(1^n, z)$ such that

1. The probability ensembles $\{\text{Sim}^1(1^n, z)\}_{n \in \mathbb{N}, z \in \{0,1\}^*}$ and $\{\text{View}^{\mathcal{A}}(1^n, z)\}_{\lambda \in \mathbb{N}, z \in \{0,1\}^*}$ are computationally indistinguishable over n , where $\text{Sim}^1(1^n, z)$ denotes the first output of $\text{Sim}(1^n, z)$.
2. Let $z \in \{0,1\}^*$ and let (View, \tilde{w}) denote the output of $\text{Sim}(1^n, z)$. Let \tilde{x} be the right-session statement appearing in View and let id and $\tilde{\text{id}}$ be the identities of the left and right sessions appearing in View . If the right session is accepting and $\text{id} \neq \tilde{\text{id}}$, then $\text{Rel}_L(\tilde{x}, \tilde{w}) = 1$.

The above definition, is easily extended to parallel NMZK, where the adversary interacts with a polynomially bounded sessions on the left and right in parallel. For our construction, we will require that only the statements are delayed while the witness is fixed in the first message sent by the prover. In the case of 4 round NMZK presented in [COSV16], this requires only a minor modification presented below.

A.5.1 COSV NMZK

We present the 4 round delayed-input NMZK protocol Π_{COSV} [COSV16].

1. a 4-round public-coin extractable one-one NM commitment scheme $\Pi_{\text{nmex}} = \langle C_{\text{nmex}}, R_{\text{nmex}} \rangle$; [COSV16] instantiates this using the non-malleable commitment scheme constructed in the same paper.
2. a signature scheme $\Sigma = (\text{Gen}, \text{Sign}, \text{Ver})$;
3. a delayed-input adaptive-input statistical WIAoK protocol $\text{sLS} = (P_{\text{sLS}}, V_{\text{sLS}})$ for the language

$$\Lambda = \left\{ (\tau_k = (\pi_{\text{nmex}}^1, \pi_{\text{nmex}}^2, \pi_{\text{nmex}}^3, \pi_{\text{nmex}}^4), \text{id}, \text{vk}, x, s_1) : \exists (s_0, \text{dec}, \text{msg}_1, \text{msg}_2, \sigma_1, \sigma_2) \right. \\ \left. \text{s.t. } \left((R_{\text{nmex}} \text{ on input } (\tau, w, \text{dec}, \text{id}) \text{ accepts } w \text{ as decommitment of } \tau \right. \right. \\ \left. \left. \text{AND } (x, s_0 \oplus s_1) \in \text{Rel}_L \right) \text{ OR } (\text{Ver}(\text{vk}, \text{msg}_1, \sigma_1) = 1 \text{ AND } \text{Ver}(\text{vk}, \text{msg}_2, \sigma_2) = 1 \right. \right. \\ \left. \left. \text{AND } \text{msg}_1 \neq \text{msg}_2) \right) \right\}$$

that is adaptive-input statistical WI and adaptive-input AoK for the corresponding relation Rel_Λ .

Common input: security parameter n , the instance length ℓ of sLS and P_{nmzk} 's identity $\text{id} \in \{0,1\}^n$, and the instance x is available only at the last round.

Private input of P_{nmzk} w s.t. $(x, w) \in \text{Rel}_L$ available only in the last round.

1. $V_{\text{nmzk}} \rightarrow P_{\text{nmzk}}$
 - (a) $(\text{sk}, \text{vk}) \leftarrow \text{Gen}(1^n)$.
 - (b) $\pi_{\text{sLS}}^1 \leftarrow V_{\text{sLS}}(1^n, \ell)$.
 - (c) $\pi_{\text{nmex}}^1 \leftarrow R_{\text{nmex}}(1^n, \text{id})$.

- (d) Send $(vk, \pi_{\text{sLS}}^1, \pi_{\text{nmex}}^2)$ to P_{nmzk}
2. $P_{\text{nmzk}} \rightarrow V_{\text{nmzk}}$
- (a) $\pi_{\text{sLS}}^2 \leftarrow P_{\text{sLS}}(1^n, \ell, \pi_{\text{sLS}}^1)$.
- (b) $s_0 \xleftarrow{\$} \{0, 1\}^{|w|}$.
- (c) $\pi_{\text{nmex}}^2 \leftarrow C_{\text{nmex}}(1^n, \text{id}, \pi_{\text{nmex}}^2, s_0)$.
- (d) $\text{msg} \xleftarrow{\$} \{0, 1\}^n$.
- (e) Send $(\pi_{\text{sLS}}^2, \pi_{\text{nmex}}^2, \text{msg})$ to V_{nmzk} .
3. $V_{\text{nmzk}} \rightarrow P_{\text{nmzk}}$
- (a) $\pi_{\text{sLS}}^3 \leftarrow V_{\text{sLS}}(\pi_{\text{sLS}}^2)$.
- (b) $\pi_{\text{nmex}}^3 \leftarrow R_{\text{nmex}}(\pi_{\text{nmex}}^2)$.
- (c) $\sigma \leftarrow \text{Sign}(\text{sk}, \text{msg})$.
- (d) Send $(\pi_{\text{sLS}}^3, \pi_{\text{nmex}}^3, \sigma)$ to P_{nmzk} .
4. $P_{\text{nmzk}} \rightarrow V_{\text{nmzk}}$
- (a) If $\text{Ver}(vk, \text{msg}, \sigma) \neq 1$ then abort, else continue.
- (b) Set $s_1 := w \oplus s_0$.
- (c) $(\text{dec}, \pi_{\text{nmex}}^4) \leftarrow C_{\text{nmex}}(\pi_{\text{nmex}}^3)$.
- (d) Set $x_{\text{sLS}} := (\pi_{\text{nmex}}^1, \pi_{\text{nmex}}^2, \pi_{\text{nmex}}^3, \pi_{\text{nmex}}^4, \text{id}, vk, x, s_1)$ and $w_{\text{sLS}} := (s_0, \text{dec}, \perp, \perp, \perp, \perp)$.
- (e) $\pi_{\text{sLS}}^4 \leftarrow P_{\text{sLS}}(\pi_{\text{sLS}}^3, x_{\text{sLS}}, w_{\text{sLS}})$.
- (f) Send $(\pi_{\text{sLS}}^4, \pi_{\text{nmex}}^4, s_1)$ to V_{nmzk} .
5. V_{nmzk} : Set $x_{\text{sLS}} := (\pi_{\text{nmex}}^1, \pi_{\text{nmex}}^2, \pi_{\text{nmex}}^3, \pi_{\text{nmex}}^4, \text{id}, vk, x, s_1)$ and accept iff $V_{\text{sLS}}(x_{\text{sLS}}, \pi_{\text{sLS}}^1, \pi_{\text{sLS}}^2, \pi_{\text{sLS}}^3, \pi_{\text{sLS}}^4) = 1$.

We use a slight modification for our setting in the five round case. In the original protocol, both the statement and the witness are known only in the last round. Since the witness is known at the start of the protocol, instead of using s_0 and s_1 , we commit to w in the first round of the non-malleable commitment. The necessary changes are made in the language.

The informal theorem regarding the security of the above protocol is:

Theorem 13 ([COSV16]). *Assuming CRHFs, the above protocol is a secure NMZK.*

In terms of concrete instantiations, CRHFs can be instantiated from DL, and hence from DDH.

We note that this NMZK scheme is also parallel ZK since we can extract trapdoors of the multiple executions in parallel.

A.6 Extractable Commitment Scheme

We will also use a simple challenge-response based extractable statistically-binding string commitment scheme $\langle C, R \rangle$ that has been used in several prior works, most notably [PRS02, Ros04]. We note that in contrast to [PRS02] where a multi-slot protocol was used, here (similar to [Ros04]), we only need a one-slot protocol.

Protocol $\langle C, R \rangle$. Let $\text{com}(\cdot)$ denote the commitment function of a non-interactive perfectly binding string commitment scheme which requires the assumption of injective one-way functions for its construction. Let n denote the security parameter. The commitment scheme $\langle C, R \rangle$ is described as follows.

COMMIT PHASE:

1. To commit to a string \mathbf{str} , C chooses $k = \omega(\log(n))$ independent random pairs $\{\alpha_i^0, \alpha_i^1\}_{i=1}^k$ of strings such that $\forall i \in [k], \alpha_i^0 \oplus \alpha_i^1 = \mathbf{str}$; and commits to all of them to R using com . Let $B \leftarrow \text{com}(\mathbf{str})$, and $A_i^0 \leftarrow \text{com}(\alpha_i^0)$, $A_i^1 \leftarrow \text{com}(\alpha_i^1)$ for every $i \in [k]$.
2. R sends k uniformly random bits v_1, \dots, v_n .
3. For every $i \in [k]$, if $v_i = 0$, C opens A_i^0 , otherwise it opens A_i^1 to R by sending the appropriate decommitment information.

OPEN PHASE: C opens all the commitments by sending the decommitment information for each one of them.

For our construction, we require a modified extractor for the extractable commitment scheme. The standard extractor returns the value \mathbf{str} that was committed to in the scheme. Instead, we require that the extractor return i , and the openings of A_i^0 and A_i^1 . This extractor can be constructed easily, akin to the standard extractor for the extractable commitment scheme.

This completes the description of $\langle C, R \rangle$.

“Rewinding secure” Commitment Scheme. Due to technical reasons, we will also use a minor variant, denoted $\langle C', R' \rangle$, of the above commitment scheme which will be rewinding secure. Protocol $\langle C', R' \rangle$ is the same as $\langle C, R \rangle$, except that for a given receiver challenge string, the committer does not “open” the commitments, but instead simply reveals the appropriate committed values (without revealing the randomness used to create the corresponding commitments). More specifically, in protocol $\langle C', R' \rangle$, on receiving a challenge string v_1, \dots, v_n from the receiver, the committer uses the following strategy: for every $i \in [k]$, if $v_i = 0$, C' sends α_i^0 , otherwise it sends α_i^1 to R' . Note that C' does not reveal the decommitment values associated with the revealed shares.

The scheme is rewinding secure because we can respond to queries from the adversary (for the commitment scheme) when we need to rewind it, and the commitment scheme is exposed to an external challenger. This follows from the fact that we can send random messages in the third round when the adversary makes a different second round query.

When we use $\langle C', R' \rangle$ in our main construction, we will require the committer C' to prove the “correctness” of the values (i.e., the secret shares) it reveals in the last step of the commitment protocol. In fact, due to technical reasons, we will also require the the committer to prove that the commitments that it sent in the first step are “well-formed”. Below we formalize both these properties in the form of a *validity* condition for the commit phase.

Proving Validity of the Commit Phase. We say that commit phase between C' and R' is *well formed* with respect to a value $\hat{\mathbf{str}}$ if there exist values $\{\hat{\alpha}_i^0, \hat{\alpha}_i^1\}_{i=1}^k$ such that:

1. For all $i \in [k]$, $\hat{\alpha}_i^0 \oplus \hat{\alpha}_i^1 = \hat{\mathbf{str}}$, and
2. Commitments B , $\{A_i^0, A_i^1\}_{i=1}^k$ can be decommitted to $\hat{\mathbf{str}}$, $\{\hat{\alpha}_i^0, \hat{\alpha}_i^1\}_{i=1}^k$ respectively.
3. Let $\bar{\alpha}_1^{v_1}, \dots, \bar{\alpha}_k^{v_k}$ denote the secret shares revealed by C in the commit phase. Then, for all $i \in [k]$, $\bar{\alpha}_i^{v_i} = \hat{\alpha}_i^{v_i}$.

We state a simple lemma below, that states that \exists an extractor E that extracts the correct committed value with overwhelming probability if the commitment is well formed. This lemma is implicit from [Ros04, PRS02].

Lemma 1. *If the validity condition for the commitment protocol holds, then E fails to extract the committed value with only negligible probability.*

We can define *validity* condition for the commitment protocol $\langle C, R \rangle$ in a similar manner.

B Proofs From Section 3

B.1 Proof of Theorem 4

We only need to argue about the output of P_3 . From the correctness of OT_{12} , it follows that P_1 recovers $x_1x_2 + r'_2$ in Round 2. From the correctness of OT_{23} , it follows that P_3 recovers $\alpha'' = x_3r'_2 + r_2$. Finally, from the correctness of OT_{13} , it follows that P_3 recovers $\alpha' = (x_1x_2 + r'_2)x_3 + r_1$. Note that $\alpha' + \alpha'' = x_1x_2x_3 + r_1 + r_2$, as desired.

B.2 Proof of Theorem 5

We consider all maximal sets of corruptions and argue security. In each case, we construct a simulator that sends pseudorandom messages in the first two rounds.

P_1 and P_2 are corrupted: In this case, simulator (Sim^1) essentially runs honest P_3 algorithm but with input $x_3 = 0$. In the final (fourth) round, the simulator (Sim^2) upon receiving as input $((3\text{MULT}((x_1, r_1); (x_2, r_2); x_3) = (\alpha_1, \alpha_2, \alpha_3)), (x_1, r_1), (x_2, r_2))$, it outputs α_3 .

The the security requirement of the robust semi honest MPC follows from that of oblivious transfer protocol and the covert security property of OT. The covertness gives us the desired joint distribution

P_1 and P_3 are corrupted: The simulator runs the honest P_2 with input $x_2 = 0$. Note that the output of P_1 and P_3 are r_1 and $r_1 + r_2$ respectively. In the final round, the simulator upon receiving as input $(3\text{MULT}((x_1, r_1); (x_2, r_2); x_3) = (\alpha_1, \alpha_2, \alpha_3)), (x_1, r_1), x_3)$, outputs $\alpha_3 + r_1$ (which is of the form $x_1x_2x_3 + r_2$).

The the security requirement of the robust semi honest MPC follows from that of oblivious transfer protocol and the covert security property of OT. The covertness gives us the desired joint distribution

P_2 and P_3 are corrupted: This is symmetrical to the previous case. Following a similar argument we result in the simulator outputting $x_1x_2x_3 + r_1$, P_2 outputs r_2 and P_3 outputs $r_1 + r_2$.

B.3 Proof of Theorem 6

Let the additive shares of 0 distributed by P_i be $\{s_0^{i,j}\}_{j \in [n]}$. Consider a term t in the expansion of p . Without loss of generality, let $\mathbf{y}_i, \mathbf{y}_j$ and \mathbf{y}_k be the variables in the expansion of t . From the correctness of $\Pi_{\text{sh}}^{3\text{MULT}}$, it follows that at the end of third round, P_i, P_j and P_k have shares of $x_i x_j x_k$. Denote these additive shares by α_i^t, α_j^t and α_k^t . At the end of the protocol, the share computed by P_i is total sum of $\sum_{i,j} s_0^{i,j}$ and the sum of shares corresponding to every term t in p . Observe that $\sum_{i,j} s_0^{i,j}$ is 0 and the sum of shares corresponding to every term t in p is $p(x_1, \dots, x_n)$.

B.4 Proof of Theorem 7

Suppose S is the set of corrupted parties controlled by adversary \mathcal{A} . We describe a simulator Sim that simulates the corrupted parties in S .

Description of Simulator. Recall that for every polynomial p , an instantiation of $\Pi_{\text{sh}}^{3\text{MULT}}$ is executed. Consider a term t in the expansion of p . We look at two cases:

- Case 1: t contains one variable associated with party not in S and contains another variable with party associated with a party in S : In this case, Sim executes the simulator, denoted by $\text{Sim}_{3\text{MULT}}$, of $\Pi_{\text{sh}}^{3\text{MULT}}$. Recall that in the fourth round, $\text{Sim}_{3\text{MULT}}$ takes as input the output of the functionality as well as the inputs and randomness of all the adversaries. In particular, Sim internally computes the functionality by setting the inputs of all the honest parties to 0 and this is input to $\text{Sim}_{3\text{MULT}}$.
- Case 2: t contains only variables associated with parties in S : The protocol associated with t is executed solely by adversarial parties.

The only remaining case was when t does not contain any variable associated with a party in S . In this case, the simulator Sim upon receiving the input $(p(x_1, \dots, x_n), \{x_i, r_i\}_{i \in S})$, generates the final round messages as follows: it computes $\alpha = p(x_1, \dots, x_n) - \beta$, where β is the summation of all the terms in the expansion of p such that these terms contain only variables associated with parties in S . The simulator then computes the final round messages of all the honest parties to be shares of the value α .

The above described simulator satisfies Definition 1 from the fact that $\Pi_{\text{sh}}^{3\text{MULT}}$ is a robust semi-honest MPC, and the fact that the last messages generated by the simulator is distributed identically to the last messages generated by the honest parties in the real world.

B.5 Proof of Theorem 8

We describe the simulator below.

Description of Simulator Sim. Let C be the circuit implementing the functionality F . Execute $\text{CktE}(C)$ to get (p_1, \dots, p_m) . Execute the simulator $\text{Sim}_{3\text{POLY}\{p_i\}}$ for every $i \in [m]$ for the first three rounds.

In the final round, Sim receives as input $(F(x_1, \dots, x_n), \{x_i, r_i\}_{i \in S})$. It first executes the simulator of RP on input $F(x_1, \dots, x_n)$ to obtain (β_1, \dots, β) . It then executes the final round of $\text{Sim}_{3\text{POLY}\{p_i\}}$ on input $((\beta_1, \dots, \beta_n), \{x_i, r_i\}_{i \in S})$ for every $i \in [m]$. Denote the outputs of the simulators to be $\vec{\alpha} = (\alpha_1, \dots, \alpha_m)$. Output $\vec{\alpha}$.

We now prove that the simulator satisfies definition 1 by hybrid argument.

Hybrid Hyb_0 : This corresponds to the real world.

Hybrid Hyb_1 : In this hybrid, execute the simulator $\text{Sim}_{3\text{POLY}\{p_i\}}$ for every $i \in [m]$ for the first three rounds. In the final round, execute $\text{Sim}_{3\text{POLY}\{p_i\}}$ on input $(\beta_i, \{x_i, r_i\}_{i \in S})$, where β_i is computed by evaluating p_i honestly on the inputs of all the parties. The output of Sim is just a concatenation of outputs of $\text{Sim}_{3\text{POLY}\{p_i\}}$ for every i .

The indistinguishability of Hyb_0 and Hyb_1 follows from the security of $\Pi_{\text{sh}}^{3\text{POLY}\{p\}}$.

Hybrid Hyb_2 : This hybrid corresponds to the ideal world.

Observe that in Hyb_1 , the $\{\beta_i\}$ input to $\text{Sim}_{3\text{POLY}\{p_i\}}$ is identically distributed to the encoding of the circuit according to RP. We can now invoke the security of RP to argue the indistinguishability of Hyb_2 and Hyb_3

Thus, from the indistinguishability of the hybrids and the fact that $\text{Sim}_{3\text{POLY}\{p\}}$ satisfies Definition 1, Π_{sh}^F is a robust semi honest MPC.

B.6 Special Rewinding property

We highlight a special property of our constructed four round robust semi-honest MPC, which we shall refer to as the “special rewinding” property. This will be useful for the proof of our five round construction. Roughly, the property states that the second round of the robust semi honest MPC can be simulated without knowledge of the input and randomness used in the first round.

Claim 1. Let h_i (resp. a_i) denote all the messages sent by the honest (resp. adversarial) parties in the i -th round. Then the following joint distributions are indistinguishable: (h_1, a_1, h_2) and (h_1, a'_1, h'_2) where h'_2 generated without knowledge of random coins and inputs used to compute h_1 .

This need not be true in general, but we shall argue that it holds in our case.

Proof sketch. Our construction of the robust semi honest MPC relies on the computation of m randomized polynomials. We argue that the property holds for any monomial, and this can be extended to the case of the polynomials. While there are common inputs across various monomials and polynomials, each monomial samples independent randomness for its computation and this suffices to let us argue them separately. The main property of our underlying construction we will use is of the security of the OT.

From the construction of $\Pi_{\text{sh}}^{\text{3POLY}\{p\}}$, which internally invokes $\Pi_{\text{sh}}^{\text{3MULT}}$, each player has a specific role for a given monomial: (i) it is not involved; (ii) involved and has a predefined role of either P_1, P_2 or P_3 . Where P_1, P_2 and P_3 have roles as described in $\Pi_{\text{sh}}^{\text{3MULT}}$. The first case is trivial since we don't need to send anything. Let us consider the 3 other cases. If the player has the role of P_1 , then by construction it is not required to send anything in the first round. If the player has the role of P_2 , then it has to respond to two OT messages in round 2. But since it has not sent a message in $\Pi_{\text{sh}}^{\text{3MULT}\{p\}}$ prior to round 2, these messages can be simulated by picking random input values as input for P_2 and respond "honestly" with these inputs. This works because the values sent in the OT are masked by r_2 and r'_2 which are generated independently for each monomial, and not used prior to round 2. Lastly, if the player has the role of P_3 , it sends the first message of an OT in round 2. Specifically, it sends the first (receiver) message of OT as a function of its input x_3 . It is important to note that P_3 has also sent an OT message in round 1 as a function of the same message, but by the receiver security of OT we can pick a random value x'_3 to simulate the OT message in round 2.

In our proof, we shall need this property to respond to (potentially different) queries sent by the adversary, in the first round, while rewinding when we argue security via the robust semi-honest MPC. As will become apparent in the proof, we will not need to complete the entire protocol simulating the second round as above.

C Proof of Theorem 9

We present the proof for our five round construction below. Before we proceed to the simulator, we discuss a few properties of the underlying primitives that we will need:

- Recall that simulator for the robust semi honest MPC consists of two parts. The first part, $\text{Sim}_{\text{rMPC}}^1$, simulates the first three rounds of the robust semi honest MPC without requiring inputs or outputs of the adversary. The second part, $\text{Sim}_{\text{rMPC}}^2$, when given the inputs, random tape and outputs a simulated transcript of the last round that is consistent with the input and randomness. Additionally, note that this simulation succeeds as long as the adversary behaved honestly in the first three rounds of the robust semi honest MPC.
- The extractor for the 3 round "rewinding secure" extractable commitment works by rewinding the second and third round polynomial number of times. From Lemma 1, we know that if the commitments are well formed, extraction fails with only negligible probability.
- The simulator of the NMZKs works by extracting a trapdoor. Specifically, it rewinds the second and third round polynomial number of times to get signatures for two distinct messages. Further, this extraction fails only with negligible probability.

- Combining the above two properties, we see that the rewindings of NMZK and the “rewinding secure” extractable commitment are “composable” because they rewind in the same rounds in our MPC protocol.
- The four round non-malleable commitment inside the NMZK rewinds in the third and fourth round. This will be useful will arguing the proofs in the hybrids.

We describe the ideal world simulator Sim below. We shall denote the set of honest players by \mathcal{H} and the set of corrupted players by $\mathcal{P}^{\mathcal{A}}$.

1. The first three rounds of protocol are simulated as follows:

- For the robust semi honest MPC, since $\text{Sim}_{\text{MPC}}^1$ doesn’t require any input or output to simulate the first three rounds, we use it directly to obtain $\{m_i^1, m_i^2, m_i^3\}_{P_i \in \mathcal{H}}$. Since the robust semi honest MPC starts from the second round, $\{m_i^3\}_{P_i \in \mathcal{H}}$ is sent in the 4th round with the last round of the NMZK for L , but we group them here for simplicity.
- For simulating proofs for the NMZKs, we deal with three different cases:
 - (a) For proofs from the adversary, the honest player acts as a verifier. In this case, fix a random tape for the verifier and respond honestly to adversary queries.
 - (b) For proofs within honest players, we fix the random tape for the verifiers and thus can trivially compute the trapdoor in the NMZKs for both languages using the verifier’s random tape.
 - (c) For proofs from honest players to the adversary, we run the simulators Sim_{nmzk} and $\widehat{\text{Sim}}_{\text{nmzk}}$ to simulate the first three rounds. This internally rewinds polynomial many times to obtain the trapdoors. If the extractor fails, output \perp_{nmzk} and abort.

This gives us $\{\pi_{\text{nmzk}_i}^j\}_{j \in \{1,2,3\}, P_i \in \mathcal{H}}$ and $\{\widehat{\pi}_{\text{nmzk}_i}^j\}_{j \in \{1,2,3\}, P_i \in \mathcal{H}}$ and the extracted trapdoors.

- For the “rewinding secure” extractable commitment, we deal with two cases:
 - (a) For commitments from the honest players to the adversary, we just commit to the all ‘0’ string. We do this for commitments within the honest players as well.
 - (b) For commitments where the honest players are recipients, run the extractor to send responses and extract the values inside the commitments. If extractor fails, output \perp_{rext} and abort.

This gives us $\{\pi_{\text{rext}_i}^j\}_{j \in \{1,2,3\}, P_i \in \mathcal{H}}$ and the extracted commitments.

As noted earlier, the rewinding performed within the NMZK simulator and the extractor for “rewinding secure” extractable commitments work in the same rounds and can be done for each without affecting the other.

2. Simulate the last round of the NMZK for L in two steps.

- For proofs from the honest parties to the adversary, use Sim_{nmzk} with inputs $\{\pi_{\text{nmzk}_{i \rightarrow k}}^j\}_{j \in \{1,2,3\}, P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}}$ and the trapdoors obtained earlier to compute

$$\{\pi_{\text{nmzk}_{i \rightarrow k}}^4\}_{P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}}.$$

- For proofs within honest parties, the trapdoor is trivially known to the adversary and thus use $\{\pi_{\text{nmzk}_{i \rightarrow k}}^j\}_{j \in \{1,2,3\}, P_k, P_i \in \mathcal{H}}$ to construct

$$\{\pi_{\text{nmzk}_{i \rightarrow k}}^4\}_{P_k, P_i \in \mathcal{H}}.$$

This gives us the required $\{\pi_{\text{nmzk}_i}^4\}_{P_i \in \mathcal{H}}$.

On receiving the proofs from the adversary check if all the received proofs are valid i.e. verify if $\{\pi_{\text{nmzk}_{k \rightarrow i}}^j\}_{j \in \{1,2,3,4\}, P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}}$ are valid proofs in L (This is equivalent to checking if all proofs in the protocol verify). If the check fails, send **abort** to the ideal functionality.

3. We perform an additional check before we obtain the final round of the robust semi honest MPC. Given $\vec{m}^1, \vec{m}^2, \vec{m}^3, \{(x_k, r_k)\}_{P_k \in \mathcal{P}^{\mathcal{A}}}$, we check if the adversary has followed the computation in the first three rounds correctly. If the check fails we output \perp_{rMPC}^1 and abort. It is implicit that the proofs for L have verified prior to this step.

4. Send the extracted inputs $\{x_k\}_{P_k \in \mathcal{P}^{\mathcal{A}}}$ to the ideal functionality to obtain the output y .

Compute the final round (of all players) of the robust semi honest MPC as

$$\{m_i^4\}_{P_i \in \mathcal{P}} \leftarrow \text{Sim}_{\text{rMPC}}^2(\vec{m}^1, \vec{m}^2, \vec{m}^3, \{x_k\}_{P_k \in \mathcal{P}^{\mathcal{A}}}, \{r_k\}_{P_k \in \mathcal{P}^{\mathcal{A}}}, y).$$

Additionally, simulate the last round of the NMZK for \widehat{L} . This is done in two steps

– For proofs from the honest parties to the adversary, use $\widehat{\text{Sim}}_{\text{nmzk}}$ with inputs $\{\widehat{\pi}_{\text{nmzk}_{i \rightarrow k}}^j\}_{j \in \{1,2,3\}, P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}}$ and the trapdoors obtained earlier to compute

$$\{\widehat{\pi}_{\text{nmzk}_{i \rightarrow k}}^4\}_{P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}}.$$

– For proofs within honest parties, the trapdoor is trivially known to the adversary and thus use $\{\widehat{\pi}_{\text{nmzk}_{i \rightarrow k}}^j\}_{j \in \{1,2,3\}, P_k, P_i \in \mathcal{H}}$ to construct

$$\{\widehat{\pi}_{\text{nmzk}_{i \rightarrow k}}^4\}_{P_k, P_i \in \mathcal{H}}.$$

This gives us the required $\{\widehat{\pi}_{\text{nmzk}_i}^4\}_{P_i \in \mathcal{H}}$.

5. On receiving the proofs from the adversary check if all the received proofs are valid, i.e. verify if $\{\widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}^j\}_{j \in \{1,2,3,4\}, P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}}$ are valid proofs in \widehat{L} . If the check fails, send **abort** to the ideal functionality.

Otherwise, on receiving $\{m_k^{*4}\}_{P_k \in \mathcal{P}^{\mathcal{A}}}$ from the adversary, we check if it matches the transcript simulated by $\text{Sim}_{\text{rMPC}}^2$ earlier. If not, but the proofs above have verified output \perp_{rMPC}^2 and abort. Else send **continue** to the ideal functionality.

We prove security via a sequence of hybrids H_0 to H_6 described below, where H_0 is the real execution and H_6 is the ideal execution. To do so, we will require the following random variables:

- Let v^r be the random variable that represents the output (including the view of the adversary and the output of the honest players). To prove security of the MPC, we need to show that the random variables v^0 and v^5 are computationally indistinguishable.
- Let $\{W_{k \rightarrow i}, \widehat{W}_{k \rightarrow i}\}_{P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}}$ be random variables representing the values that are committed in the extractable non-malleable commitment within the NMZK. We need these to ensure that adversary behaves in a semi-honest way in the computation of the robust semi honest MPC.

Public-coin property of non-malleable commitment. During our proofs, we reduce our indistinguishability argument to a specific cryptographic property that holds in the stand-alone setting. We might require the non-malleable commitment to interact with an external party R . Note that the simulator will often rewind the adversary. But since R is a stand-alone receiver, its responses can be used only in a single thread.

To deal with this, we do the following. On the main thread, any message from the adversary is forwarded externally to R , and responses from R are forwarded internally to the adversary. But in the look ahead threads, we use the public coin property of the non-malleable commitment to create responses on our own and forward them internally to the adversary.

H₀: Execution of the protocol Π in the real world with adversary \mathcal{A} .

Soundness lemma. We claim an important lemma that is relevant to the real execution. The lemma says that the adversary \mathcal{A} commits to valid witnesses in the extractable non-malleable commitment inside each non-malleable zero knowledge proofs, where it acts as the prover, if the proof verify.

Lemma 2. Let $\{\pi_{\text{nmzk}_{k \rightarrow i}}\}_{P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}}$ and $\{\widehat{\pi}_{\text{nmzk}_{k \rightarrow i}}\}_{P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}}$ be the NMZK proofs for L and \widehat{L} respectively that \mathcal{A} sends to all the honest players. Let $p_{k \rightarrow i}$ and $\widehat{p}_{k \rightarrow i}$ correspond to the probabilities that $W_{k \rightarrow i}^0$ and $\widehat{W}_{k \rightarrow i}^0$ are not valid witnesses for the statements being proved in the NMZKs above. For the real execution, if all the proofs are accepting, then

$$p_{k \rightarrow i}, \widehat{p}_{k \rightarrow i} < \nu(n) \quad \forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{H}$$

for some negligible function ν .

The proof of the above lemma follows from a direct extension of Claim 3 in [COSV16]. The high level idea for the proof is, if by contradiction the lemma doesn't hold, then we can forge a signature for the underlying signature scheme in the NMZK.

Across hybrids, the condition that \mathcal{A} commits to valid witnesses in the extractable NMCom within the NMZK if the proofs verify will be referred to as the *soundness condition*.

H₁: Identical to **H₀** except that we rewind polynomial number of times in the second and third round to extract the trapdoors for both the non-malleable zero knowledge proofs, and the committed values (input and randomness) from the “rewinding secure” extractable commitment scheme.

We abort with output \perp_{nmzk} for the hybrid if the extractor for NMZKs fail, and abort with output \perp_{rext} if the extractor for the “rewinding secure” non-malleable commitment fails to return a value.

Since the only difference from the previous hybrid **H₀** (real execution) is the rewinding to perform the required extractions, the main thread in the experiment remains unchanged. Thus, we claim the following

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^0 \approx_s W_{k \rightarrow i}^1 \tag{1}$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^0 \approx_s \widehat{W}_{k \rightarrow i}^1 \tag{2}$$

Let us assume the claim isn't true. Without loss of generality assume equation 1 is false, the other case follows similarly. Then $\exists P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{P}$ such that $W_{k \rightarrow i}^0$ and $W_{k \rightarrow i}^1$ are distinguishable by an unbounded adversary D . We can use D to create another unbounded adversary D' that distinguishes between the main threads of **H₀** and **H₁**. It works by extracting the commitment in the extractable non-malleable commitment within the NMZK proof $\pi_{\text{nmzk}_{k \rightarrow i}}$, and uses D to distinguish between the commitments. Since the main thread is unchanged, this is a contradiction.

We now claim,

$$v^0 \approx_s v^1. \quad (3)$$

Since the main thread remains the same, all that is left to argue is that the experiment aborts with negligible probability.

From the NMZK we know that the probability \perp_{nmzk} is output is negligible in n . Similarly, we output \perp_{rext} with probability negligible in n . This implies that the experiment aborts with negligible probability, proving the claim.

If the proofs are accepting in the main thread, then the extracted values are correct by the soundness lemma and equations 1 and 2.

H₂: Identical to **H₁** except that we use the trapdoors obtained earlier to simulate the last message of the statistical witness indistinguishable argument of knowledge (statistical WIAoK), from the honest players to the adversarial players, within the NMZK proofs for languages L and \widehat{L} . For proofs between any two honest players, since the simulator controls both players, it fixes the random tapes used for the NMZK and knows the trapdoors. Thus, proofs between honest parties are trivially simulated. Proofs from the adversary are responded to honestly.

Since only the last message of each statistical WIAoK is changed, the changes in this hybrid, from the previous hybrid, are only in the fourth and fifth round.

We now claim the following,

$$v^1 \approx_s v^2 \quad (4)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^1 \approx_s W_{k \rightarrow i}^2 \quad (5)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^1 \approx_s \widehat{W}_{k \rightarrow i}^2 \quad (6)$$

Equation 4 follows from the the statistical witness indistinguishability of the statistical WIAoK.

Equations 5 and 6 hold from the fact that the above change is only a statistical one.

H₃: Identical to **H₂** except that we set random values inside the non-malleable commitment in each NMZK sent by the honest players. This is true of proofs between honest players too.

We now claim the following,

$$v^2 \approx_c v^3 \quad (7)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^2 \approx_c W_{k \rightarrow i}^3 \quad (8)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^2 \approx_c \widehat{W}_{k \rightarrow i}^3 \quad (9)$$

Equation 7 follows from the fact the hiding property of the non-malleable commitment. This does not conflict with the rewinding since only a single message of the non-malleable commitment is sent during the rewinding phase, and this can be repeated in each look ahead thread.

Equations 8 and 9 hold from the non-malleability of the non-malleable commitment.

H₄: Identical to **H₃** except for the following. With $\vec{m}^1, \vec{m}^2, \vec{m}^3, \{(x_k, r_k)\}_{P_k \in \mathcal{P}^A}$, we check if the adversary has followed the computation in the first three rounds correctly. If not, and the proofs for L verify, we output \perp_{rMPC}^1 and abort. If the proofs for L do not verify, send **abort** to the ideal functionality.

Otherwise send the inputs extracted to the ideal functionality to obtain the output. Given the extracted inputs, randomnesses and output we run $\text{Sim}_{\text{rMPC}}^2$ to obtain m_i^4 for every honest player P_i . Since it is a semi-honest simulator, it simulates the transcript, and we thus also have $\{m_k^4\}_{P_k \in \mathcal{P}^A}$. On receiving $\{m_k^{*4}\}_{P_k \in \mathcal{P}^A}$ from the adversary, checks if the simulated transcript matches the on

received. If it does not match, but the NMZK proofs for \widehat{L} verify, output \perp_{rMPC}^2 and abort. If the proofs for \widehat{L} do not verify, send **abort** to the ideal functionality.

Conditioned on the fact that we don't abort, we claim the following

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^3 \approx_s W_{k \rightarrow i}^4. \quad (10)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^3 \approx_s \widehat{W}_{k \rightarrow i}^4. \quad (11)$$

Equation 10 is trivially true since the last message that was simulated for the robust semi honest MPC was sent in the fifth round, after the completion of the NMZK for L . Thus the execution thread till the fifth round is statistically indistinguishable.

Equation 11 follows from the fact that we can rewind the non-malleable commitment to extract from it, and thus build a distinguisher breaking security of $\text{Sim}_{\text{rMPC}}^2$. There are no issues while rewinding since we receive only the last message of the robust semi-honest MPC from the challenger. The rewinding occurs only in the third and fourth messages of the non-malleable commitment. We re-send the third round message of the robust semi-honest MPC. By the soundness of the proof certifying honest behavior in the first three round, the adversary cannot deviate in its response in the third round. Thus, we can just replay the same 4th message in each look-ahead thread.

Lastly, we claim

$$v^3 \approx_c v^4. \quad (12)$$

Before we can reduce this to the security of the underlying simulator for the robust semi honest MPC, we must ensure that the security holds. This is the case when the adversary behaved semi-honestly in the first three rounds, i.e. if the proofs for L verify and the hybrid does not output \perp_{rMPC}^1 . From equation 10 and the soundness condition of the previous hybrid, if the proofs for L verify, the adversary does not behave honestly in the first three rounds with only negligible probability. Thus \perp_{rMPC}^1 is output with only negligible probability.

Then, if the above claim does not hold, we break the security of $\text{Sim}_{\text{rMPC}}^2$ (implied by the definition of the robust semi honest MPC). Additionally, if the proofs for \widehat{L} verify, from the soundness condition \perp_{rMPC}^2 is output with negligible probability. This ensures that the output distribution of the honest parties is indistinguishable from the previous hybrid. This proves our claim.

H₅: Identical to **H₄** except that we simulate the commitments of honest parties by committing to the all '0' string in the "rewinding secure" extractable commitment scheme. This applies to commitments within every pair of honest players as well.

We claim the following

$$v^4 \approx_c v^5. \quad (13)$$

Equation 13 follows from the hiding property and rewinding security of the "rewinding secure" extractable commitment scheme.

Note that we're no longer proving indistinguishability of message distribution committed in the non-malleable commitment. In the previous hybrids, we used it to establish the soundness condition. But in this, and the subsequent hybrid, if the adversary is able to send accepting proofs without behaving honestly, then from the changes implemented in the previous hybrid, we output either \perp_{rMPC}^1 or \perp_{rMPC}^2 . Since the only change in this hybrid is the values inside the "rewinding secure" extractable commitment, by observing if these special abort symbols are output, we break the hiding property of the "rewinding secure" extractable commitment scheme.

H₆: Identical to **H₅** except that we use $\text{Sim}_{\text{rMPC}}^1$ to simulate the first three round of the honest players in Π_{rMPC} .

We claim the following

$$v^5 \approx_c v^6. \tag{14}$$

Equation 14 follows from the computational indistinguishability of the the view output by $\text{Sim}_{\text{rMPC}}^1$ from the real view implicit from the definition of the robust semi honest MPC. This is where the “special rewinding” property (see B.6) is used. When we build a distinguisher for the the robust semi honest MPC, we receive the transcript externally. But in order to complete the protocol, we need to rewind to be able extract trapdoor and adversarial inputs. The rewinding happens in the second and third round of the overall protocol, and thus only the first two rounds of the robust semi honest MPC overlaps with the rewinding phase. In the look ahead threads, if we send a different message in the second round (overlapping with first round of semi-honest MPC), the adversary might send a different first message of the robust semi-honest MPC. We need the adversary to complete its second round of the robust semi honest MPC (and thus the third round of the overall protocol) to be able to extract, and hence need the “special rewinding” property to simulate messages for potentially different first round messages in the look ahead threads.

Hybrid **H₆** is identical to our simulator. From the above discussion, we have

$$v^0 \approx_c v^6$$

thus proving security of the constructed MPC.

D Proof of Theorem 10

We present the proof for our four round construction below. As before, we discuss a few properties of the underlying primitives that we will need:

- The simulator for the robust semi honest MPC, as previously discussed, consists of two parts. The first part, $\text{Sim}_{\text{rMPC}}^1$, simulates the first three rounds of the robust semi honest MPC without requiring inputs or outputs of the adversary. The second part, $\text{Sim}_{\text{rMPC}}^2$, when given the inputs and outputs of the adversary simulates the last message of robust semi honest MPC. Additionally, note that this simulation works only in the semi-honest setting.
- The extractor for the 3 round “rewinding secure” extractable commitment works by rewinding the second and third round polynomial number of times. From the Lemma 1, we know that if the commitments are well formed, extraction of the correct inputs fail with only negligible probability.
- The simulator of the NMZKs works by extracting a trapdoor. Specifically, it rewinds the second and third round polynomial number of times to get signatures for two distinct messages. Further, this extraction fails only with negligible probability.
- Combining the above two properties, we see that the rewindings of NMZK and the “rewinding secure” extractable commitment are “composable” because they rewind in the same rounds in our MPC protocol.
- The four round non-malleable commitment inside the NMZK rewinds in the third and fourth round. This will be useful will arguing the proofs in the hybrids.

We describe the ideal world simulator Sim below.

1. The first three rounds of protocol are simulated by picking random inputs for the honest parties and behaving “honestly” with these inputs as follows:

- For the robust semi honest MPC, pick random $\{x'_i, r'_i\}_{P_i \in \mathcal{H}}$ as inputs to the first three rounds. We shall use the last round of the robust semi honest MPC to correct the output. We obtain $\{m_i^1, m_i^2, m_i^3\}_{P_i \in \mathcal{H}}$.
- For the “rewinding secure” extractable commitment, we deal with two cases:
 - (a) For commitments from the honest players to the adversary, we commit honestly to random strings $\{r_{\text{ext}_i \rightarrow k}^0\}_{P_i \in \mathcal{H}}$. We do this for commitments within the honest players as well. In the third round, we send $\{r_{\text{ext}_i \rightarrow k}^1 := (x'_i, r'_i) \oplus r_{\text{ext}_i \rightarrow k}^0\}_{P_i \in \mathcal{H}}$ where x'_i, r'_i are the inputs and randomness generated in the previous step.
 - (b) For commitments where the honest players are recipients, run the extractor to send both the responses, and extract the values inside the commitments. If the extraction fails to return a value, output \perp_{ext} and abort.

This gives us $\{\pi_{\text{ext}_i}^j\}_{j \in \{1,2,3\}, P_i \in \mathcal{H}}$, $\{r_{\text{ext}_i \rightarrow k}^1\}_{P_i \in \mathcal{H}}$ and the extracted commitments.

- We generate $\{y_i\}_{P_i \in \mathcal{H}}$ honestly as defined by the protocol.
- For the non-malleable commitment, as above, we deal with two cases:
 - (a) For commitments from the honest players to the adversary, we have a valid witness for the input and randomness we generated, and thus commit to a witness consistent with the first three rounds. We do this for commitments within the honest players as well. By the construction of the NMZK protocol in [COSV16], the change for this is made only in the fourth round where we send a different mask s_1
 - (b) For commitments where the honest players are recipients, we behave honestly.

This gives us $\{\pi_{\text{nmcom}_i}^j\}_{j \in \{1,2,3\}, P_i \in \mathcal{H}}$, $\{\hat{\pi}_{\text{nmcom}_i}^j\}_{j \in \{1,2,3\}, P_i \in \mathcal{H}}$ and the masks to be sent in the fourth round.

- For the input delayed WIPoK, we behave honestly with our randomly generated inputs and randomness. This gives us $\{\pi_{\text{WIPoK}_i}^j\}_{j \in \{1,2,3\}, P_i \in \mathcal{H}}$. If any of the proofs received at the end of the third round fails, output \perp and abort.
- For simulating proofs for the NMZKs, we deal with three different cases:
 - (a) For proofs from the adversary, the honest player acts as a verifier. In this case, fix a random tape for the verifier and respond honestly to adversary queries.
 - (b) For proofs within honest players, we fix the random tape for the verifiers and thus can trivially compute the trapdoor in the NMZKs for both languages using the verifier’s random tape.
 - (c) For proofs from honest players to the adversary, we run the simulator Sim_{nmzk} . This internally rewinds polynomial many times to obtain the trapdoors. If the extractor fails, output \perp_{nmzk} and abort.

This gives us $\{\pi_{\text{nmzk}_i}^j\}_{j \in \{1,2,3\}, P_i \in \mathcal{H}}$ and the extracted trapdoors.

As noted earlier, the rewinding performed within the NMZK simulator and the extractor for “rewinding secure” extractable commitments work in the same rounds and can be done for each without affecting the other.

2. The last round is simulated as below:

- Send the extracted inputs $\{x_k\}_{P_k \in \mathcal{P}^A}$ to the ideal functionality to obtain the output y . Obtain the final round of the robust semi honest MPC as

$$\{m_i^4\}_{P_i \in \mathcal{P}} \leftarrow \text{Sim}_{\text{rMPC}}^2(\vec{m}^1, \vec{m}^2, \vec{m}^3, \{x_k\}_{P_k \in \mathcal{P}^A}, \{r_k\}_{P_k \in \mathcal{P}^A}, y).$$

- Simulate the last round of the NMZK for L in two steps.
 - For proofs from the honest parties to the adversary, use Sim_{nmzk} with inputs:

$$\left\{ \pi_{\text{nmzk}_{i \rightarrow k}}^j \right\}_{j \in \{1,2,3\}, P_k \in \mathcal{P}^A, P_i \in \mathcal{H}}$$

and the trapdoors obtained earlier to compute

$$\left\{ \pi_{\text{nmzk}_{i \rightarrow k}}^4 \right\}_{P_k \in \mathcal{P}^A, P_i \in \mathcal{H}}.$$

- For proofs within honest parties, the trapdoor is trivially known to the adversary and thus use $\left\{ \pi_{\text{nmzk}_{i \rightarrow k}}^j \right\}_{j \in \{1,2,3\}, P_k, P_i \in \mathcal{H}}$ to construct

$$\left\{ \pi_{\text{nmzk}_{i \rightarrow k}}^4 \right\}_{P_k, P_i \in \mathcal{H}}.$$

This gives us the required $\left\{ \pi_{\text{nmzk}_i}^4 \right\}_{P_i \in \mathcal{H}}$.

On receiving the proofs from the adversary check if all the received proofs are valid i.e. verify if $\left\{ \pi_{\text{nmzk}_{k \rightarrow i}}^j \right\}_{j \in \{1,2,3,4\}, P_k \in \mathcal{P}^A, P_i \in \mathcal{H}}$ are valid proofs in L . If the check fails, send **abort** to the ideal functionality. if the proofs verify, but $\{m_k^{*4}\}_{P_k \in \mathcal{P}^A}$ differs from the simulated transcript, output \perp_{rMPC}^2 .

As in the five round setting, we prove security via a sequence of hybrids using the following random variables:

- Let v^r be the random variable that represents the output (including the view of the adversary and the output of the honest players).
- Let $\{W_{k \rightarrow i}\}_{P_k \in \mathcal{P}^A, P_i \in \mathcal{H}}$ be the random variables representing the values that are committed in the non-malleable commitments of Π_{nmcom} . On the other hand, $\{\widehat{W}_{k \rightarrow i}\}_{P_k \in \mathcal{P}^A, P_i \in \mathcal{H}}$ are the random variables representing the XOR of the values committed in the non-malleable commitment within the NMZK and the mask sent in the fourth round of the NMZK (i.e. $\widehat{W}_{k \rightarrow i} := s_{k \rightarrow i}^0 \oplus s_{k \rightarrow i}^1$). We need these to ensure that adversary behaves in a semi-honest way for the computation of the robust semi honest MPC.

H₀: Execution of the protocol Π in the real world with adversary \mathcal{A} .

Soundness lemma.

Lemma 3. *Let $\{\pi_{\text{WIPoK}_{k \rightarrow i}}\}_{P_k \in \mathcal{P}^A, P_i \in \mathcal{H}}$ and $\{\pi_{\text{nmzk}_{k \rightarrow i}}\}_{P_k \in \mathcal{P}^A, P_i \in \mathcal{H}}$ be the input delayed WIPoK proofs for L_{WIPoK} and NMZK proofs for \widehat{L} respectively that \mathcal{A} sends to the honest players. Let $p_{k \rightarrow i}$ correspond to the probability that $W_{k \rightarrow i}^0$ is not a valid witness for the statement in L being proved in the input delayed WIPoK above. Similarly, $\widehat{p}_{k \rightarrow i}$ corresponds to the probability that $\widehat{W}_{k \rightarrow i}^0$ is not a valid witness for \widehat{L} . For the real execution, if the proofs are accepting, then*

$$p_{k \rightarrow i}, \widehat{p}_{k \rightarrow i} < \nu(n) \quad \forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{H}$$

for some negligible function ν .

Proof. The high level idea of the proof is the following: Suppose by contradiction the lemma is not true, then there $\exists P_k \in \mathcal{P}^A, P_k \in \mathcal{H}$ such that either $p_{k \rightarrow i}$ or $\widehat{p}_{k \rightarrow i}$ is non-negligible. We assume that $p_{k \rightarrow i}$ is non-negligible (the other case follows in a similar manner). Then we can construct an adversary \mathcal{A}_f that breaks the one-way property of f . For P_i receiving a proof, all messages, other than $y_{k \rightarrow i}$, are sent honestly. We forward the challenge received from the challenger for f . We then extract the witness from the adversary's input delayed WIPoK, thus breaking the one-wayness of f . For the other case, we will be able to construct, in a similar manner, an adversary that breaks the security of the underlying signature scheme. \square

Across hybrids, the condition that \mathcal{A} commits to valid witnesses in the non-malleable commitments if the proofs verify will be referred to as the *soundness condition*.

H₁: Identical to **H₀** except that we rewind polynomial number of times in the second and third round to extract the trapdoors for the NMZK proofs, and the committed values (input and randomness) from the “rewinding secure” extractable commitment scheme.

We abort with output \perp_{nmzk} for the hybrid if the extractor for NMZK fails, and abort with output \perp_{rext} if the extractor for the “rewinding secure” extractable commitment fails to return any output. At this point we do not know if the extracted values are indeed the adversary's input and randomness.

Since the only difference from the previous hybrid **H₀** (real execution) is the rewinding to perform the required extractions, the main thread in the experiment remains unchanged. Thus, we claim the following

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^0 \approx_s W_{k \rightarrow i}^1 \quad (15)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^0 \approx_s \widehat{W}_{k \rightarrow i}^1 \quad (16)$$

The proofs follows exactly the same as in the five round case.

We now claim,

$$v^0 \approx_s v^1. \quad (17)$$

Since the main thread remains the same, all that is left to argue is that the experiment aborts with negligible probability.

From the property of the NMZK and “rewinding secure” extractable commitments, we know that the probability \perp_{nmzk} or \perp_{rext} is output is negligible in n . This implies that the experiment aborts with negligible probability, proving the claim.

H₂: Identical to **H₁** except that we use the trapdoors obtained earlier to simulate the last message of the sWIAoK, from the honest players to the adversarial players, within the NMZK for language \widehat{L} . For proofs between any two honest players, since the simulator controls both players, it fixes the random tapes used for the NMZK and thus knows the trapdoors. Thus, proofs between honest parties are trivially simulated. For proofs from the adversary, we respond honestly.

We now claim the following,

$$v^1 \approx_c v^2 \quad (18)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^1 \approx_c W_{k \rightarrow i}^2 \quad (19)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^1 \approx_c \widehat{W}_{k \rightarrow i}^2 \quad (20)$$

Equation 18 follows from the witness indistinguishability of the statistical WIAoK.

Equation 19 holds because changes made are after the completion of the two round non-malleable commitment.

Equation 20 holds from the change only being statistical.

H₃: Identical to **H₂** except that we commit to random values in the non-malleable commitments inside the NMZKs sent by the honest players. This is done by changing the mask sent in the fourth message.

We claim the following,

$$v^2 \approx_c v^3 \quad (21)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^2 \approx_c W_{k \rightarrow i}^3 \quad (22)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^2 \approx_c \widehat{W}_{k \rightarrow i}^3. \quad (23)$$

Equation 21 follows from the hiding property of the non-malleable commitment.

Equation 22 follows from the fact that the change is made after the completion of the 2 round non-malleable commitment. Equation 23 holds from the non-malleability of the 4 round non-malleable commitment.

H₄: Identical to **H₃** except for the following changes. Send the inputs extracted to the ideal functionality to obtain the output.

Given the extracted inputs, randomnesses and output, we run $\text{Sim}_{\text{rMPC}}^2$ to simulate m_i^4 for every honest player P_i .

Since it is a semi-honest simulator, it simulates the transcript, and we thus also have $\{m_k^4\}_{P_k \in \mathcal{P}^A}$. On receiving $\{m_k^{*4}\}_{P_k \in \mathcal{P}^A}$ from the adversary, checks if the simulated transcript matches the one received. If it does not match, but the NMZK proofs for \widehat{L} verify, output \perp_{rMPC}^2 and abort. If the proofs for \widehat{L} do not verify, send **abort** to the ideal functionality.

We claim the following

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^3 \approx_s W_{k \rightarrow i}^4. \quad (24)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^3 \approx_s \widehat{W}_{k \rightarrow i}^4. \quad (25)$$

Equations 24 holds because changes made in the hybrid are after the completion of the non-malleable commitment. Equation 25 holds, else we can extract by rewinding to build a distinguisher for $\text{Sim}_{\text{rMPC}}^2$. The proof is identical to the one in the 5 round setting.

Lastly, we claim

$$v^3 \approx_c v^4. \quad (26)$$

The claim follow from the security of $\text{Sim}_{\text{rMPC}}^2$ implicit from the definition of the robust semi-honest MPC. Additionally, if the proofs for \widehat{L} verify, from the soundness condition \perp_{rMPC}^2 is output with negligible probability. This ensures the that the output distribution of the honest parties is indistinguishable from the previous hybrid. This proves our claim.

Note: Now, with the next few hybrids we shall replace the the first 3 rounds that are computed honestly with respect to the input delayed WIPoK, robust semi-honest MPC and “rewinding secure” extractable commitment using the honest players inputs (and randomness), with an honest computation of the mentioned primitives using random inputs (and randomness). For this we shall use techniques of complexity leveraging.

We assume the following, and set the security parameters for the primitives accordingly.

- $T_{\text{rMPC}_{(1-3)}}, T_{\text{WIPoK}} \gg T_{\text{rext}}, T_{\text{Sign}}$.
- $T_{\text{rMPC}_{(1-3)}} \gg T_{\text{nmcom}}$.
- $T_{\text{nmcom}} \gg T_f$.
- $T_{\text{rext}} \gg T_f$.

where T_{prim} means that the primitive prim is secure against adversaries running in time T_{prim} , and $T' \gg T$ means that $T' > T \cdot \text{poly}(n)$. Here $T_{\text{rMPC}_{(1-3)}}$ means that we require the first three rounds of our robust MPC to be indistinguishable (for adversaries running in time $T_{\text{rMPC}_{(1-3)}}$) for any two sets of inputs and randomnesses. In fact, in our construction, the simulator Sim^1 works by setting a random input to generate the first three rounds. Hence, for our construction, we require $T_{\text{rMPC}_{(1-3)}}$ -security for the following two distributions: $\text{RealExec}_{(t-1)}^{\mathcal{A}^1}(\vec{x}, z)$ and $\text{Sim}^1(z)$. Note that here nmcom refers to the two round non-malleable commitment.

H₅: Identical to **H₄** except that we stop rewinding to extract the input and trapdoor, and instead break the signature scheme and the “rewinding secure” extractable commitment to obtain the trapdoors and the adversary’s inputs.

We claim the following

$$v^4 \approx_c v^5. \quad (27)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^4 \approx_c W_{k \rightarrow i}^5. \quad (28)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^4 \approx_c \widehat{W}_{k \rightarrow i}^5. \quad (29)$$

Equation 27 follows from the fact that this was only a statistical change. For the same reason, equations 28 and 29 and hold. Note that we’re still verifying the proofs to validate the extracted values.

H₆: Identical to **H₅** except that we break the one-way permutation f , to obtain the pre-image ρ which is used as a trapdoor to simulate the input delayed WIPoKs.

We claim the following

$$v^5 \approx_c v^6. \quad (30)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^5 \approx_c W_{k \rightarrow i}^6. \quad (31)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^5 \approx_c \widehat{W}_{k \rightarrow i}^6. \quad (32)$$

Equation 30 follows from the witness indistinguishability of the input delayed WIPoK, and the fact that $T_{\text{WIPoK}} \gg T_f$, $T_{\text{WIPoK}} \gg T_{\text{rext}}$ and $T_{\text{WIPoK}} \gg T_{\text{Sign}}$. We need the latter two because we’re still breaking the primitives to extract, and the hybrid thus takes time $O(\max\{T_f, T_{\text{rext}}, T_{\text{Sign}}\})$ which is in turn less than T_{WIPoK} .

Equation 31 trivially holds since the change in the witness is performed only in the third round, after the 2 round non-malleable commitment has completed.

Assume equations 32 does not hold. Then $\exists P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}$ such that $\widehat{W}_{k \rightarrow i}^5$ and $\widehat{W}_{k \rightarrow i}^6$ are distinguishable by a PPT distinguisher D . We will use this distinguisher to break the hiding property of the security of the input delayed WIPoK. Specifically, we rewind to extract the corresponding non-malleable commitment $\widehat{W}_{k \rightarrow i}$. We need to rewind only the third and fourth rounds of the non-malleable commitment. Since only the third round of the WIPoK overlaps with the rewinding, we send the same message of the WIPoK in each look-ahead thread. We then use D to break the witness indistinguishability input delayed WIPoK.

H₇: Identical to **H₆** except that we use randomly generated inputs $\{x'_i, r'_i\}_{P_i \in \mathcal{H}}$ as inputs to the first three rounds of the robust semi honest MPC.

We claim the following

$$v^6 \approx_c v^7. \quad (33)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^6 \approx_c W_{k \rightarrow i}^7. \quad (34)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^6 \approx_c \widehat{W}_{k \rightarrow i}^7. \quad (35)$$

Equation 33 follows from the security of the first three rounds of the robust semi honest MPC and the fact that $T_{\text{rMPC}_{(1-3)}} \gg T_f$, $T_{\text{rMPC}} \gg T_{\text{rext}}$ and $T_{\text{rMPC}} \gg T_{\text{Sign}}$. The latter conditions are required as we're still breaking f , the signature scheme and the “rewinding secure” extractable commitment. As before, the hybrid takes time $O(\max\{T_f, T_{\text{rext}}, T_{\text{Sign}}\})$ which is in turn less than T_{WIPoK} .

Assume equations 34 does not hold. Then $\exists P_k \in \mathcal{P}^{\mathcal{A}}, P_i \in \mathcal{H}$ such that $W_{k \rightarrow i}^6$ and $W_{k \rightarrow i}^7$ are distinguishable by a PPT distinguisher D . We shall break the non-malleable commitment to obtain the committed value, and use D to build a distinguisher for the first three rounds of the robust semi-honest MPC. For this to hold, we require $T_{\text{rMPC}_{(1-3)}} \gg T_{\text{nmcom}}$ as assumed.

For equation 35, we can extract the value in the 4 round non-malleable commitment by just rewinding. This is because the rewinding in the third and fourth round, which overlaps with the last round of the robust semi honest MPC, and we just repeat this message in each look ahead thread.

H₈: Identical to **H₇** except that we stop breaking the signature scheme and the “rewinding secure” extractable commitment, and start rewinding again to obtain the trapdoor and the adversary's inputs.

We claim the following

$$v^7 \approx_c v^8. \quad (36)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^7 \approx_c W_{k \rightarrow i}^8. \quad (37)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^7 \approx_c \widehat{W}_{k \rightarrow i}^8. \quad (38)$$

Equation 36 follows from the fact that this was only a statistical change. For the same reason, equations 37 and 38 and hold.

H₉: Identical to **H₈** except that in the third round for every honest party P_i we send $\{r_{\text{rext}_i \rightarrow k}^1 := (x'_i, r'_i) \oplus r_{\text{rext}_i \rightarrow k}^0\}_{P_i \in \mathcal{H}}$. Where $r_{\text{rext}_i \rightarrow k}^0$ was the corresponding message sent inside the the “rewinding secure” extractable commitment in the first round, and $\{x'_i, r'_i\}_{P_i \in \mathcal{H}}$ are the input and randomness generated and used in the first three rounds of the MPC. Thus, alternatively we view the corresponding “rewinding secure” extractable commitment scheme to contain $r_{\text{rext}_i \rightarrow k}^1 \oplus (x'_i, r'_i)$ by making changes only in the third round.

We claim the following

$$v^8 \approx_c v^9. \quad (39)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^8 \approx_c W_{k \rightarrow i}^9. \quad (40)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^8 \approx_c \widehat{W}_{k \rightarrow i}^9. \quad (41)$$

Equation 39 follows from the hiding property of the “rewinding secure” extractable commitment scheme and the fact that $T_{\text{rext}} \gg T_f$. The latter is required as we're still breaking f to simulate

the input delayed WIPoK. To see why the hiding property helps, one can think of an intermediate hybrid where we send random values instead of $r_{\text{ext}_i \rightarrow k}^1$. Since the mask to the input and randomness are hidden in the “rewinding secure” extractable commitment, the adversary’s view remain indistinguishable when we make this change. Note that we’re still rewinding to extract trapdoors and inputs from the adversary. This is not a problem because of the rewinding security of the “rewinding secure” extractable scheme.

Equation 40 trivially holds since the changes are made after the two round non-malleable commitment completes.

Assume 41 does not hold. Then $\exists P_k \in \mathcal{P}^A, P_i \in \mathcal{H}$ such that $\widehat{W}_{k \rightarrow i}^8$ and $\widehat{W}_{k \rightarrow i}^9$ are distinguishable by a PPT distinguisher D . We shall extract the values inside the non-malleable commitment to break the hiding property of the “rewinding secure” extractable commitments using D . Here, unlike the previous hybrids, we can extract from the non-malleable commitment by rewinding. This follows from the rewinding security of the “rewinding secure” extractable commitment, and we can thus respond to potentially different queries to the challenger from the adversary when rewinding to extract from the non-malleable commitment.

H₁₀: Identical to **H₉** except that in the non-malleable commitment sent by the honest players, we commit to $\{x'_i, r'_i\}_{P_i \in \mathcal{H}}$ and the randomness used in the “rewinding secure” extractable commitment. Where $\{x'_i, r'_i\}_{P_i \in \mathcal{H}}$ are the input and randomness generated, and used, in the first three rounds of the MPC (and committed to in the “rewinding secure” extractable commitment). Thus, the values inside the non-malleable commitments will be valid witnesses of L for the messages sent as “honest” computation by the honest players.

We claim the following

$$v^9 \approx_c v^{10}. \quad (42)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^9 \approx_c W_{k \rightarrow i}^{10}. \quad (43)$$

$$\forall P_k \in \mathcal{P}^A, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^9 \approx_c \widehat{W}_{k \rightarrow i}^{10}. \quad (44)$$

Equation 42 follows from the hiding property of the non-malleable commitment scheme and the fact that $T_{\text{nmcom}} \gg T_f$. The latter condition is required as we’re still breaking f . Note that we’re still rewinding to extract trapdoors and inputs from the adversary. This is not a problem because we rewind only in the second and third rounds, and with a two round non-malleable commitment, we send the same second message in every look ahead thread.

Equations 43 follows directly from the non-malleability of the non-malleable commitment scheme.

Assume that 44 doesn’t hold. Then $\exists P_k \in \mathcal{P}^A, P_i \in \mathcal{H}$ such that $\widehat{W}_{k \rightarrow i}^9$ and $\widehat{W}_{k \rightarrow i}^{10}$ are distinguishable by a PPT distinguisher D . We extract from the four round non-malleable commitment (inside the NMZK) to break the hiding property of the two round non-malleable commitment scheme. The extraction is done by rewinding the third and fourth round, and since none of the two round non-malleable commitment scheme overlaps with the rewinding rounds, we are fine. Now we use the D to break the hiding property of the commitment scheme.¹³

H₁₁: Identical to **H₁₀** except that we stop rewinding to extract the input, and instead break the signature scheme and the “rewinding secure” extractable commitment to obtain the trapdoor and the adversary’s inputs.

We claim the following

¹³See remark 1 at the end of the proof.

$$v^{10} \approx_c v^{11}. \quad (45)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^{10} \approx_c W_{k \rightarrow i}^{11}. \quad (46)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^{10} \approx_c \widehat{W}_{k \rightarrow i}^{11}. \quad (47)$$

Equation 45 follows from the fact that this was only a statistical change. For the same reason, equations 46 and 47 and hold.

H₁₂: Identical to **H₁₁** except that we stop breaking the one-way permutation to obtain the trapdoor, and instead use the valid witness we committed to in non-malleable commitment in the previous hybrid to complete the input delayed WIPOK proofs.

We claim the following

$$v^{11} \approx_c v^{12}. \quad (48)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^{11} \approx_c W_{k \rightarrow i}^{12}. \quad (49)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^{11} \approx_c \widehat{W}_{k \rightarrow i}^{12}. \quad (50)$$

Equation 48 follows from the witness indistinguishability property of the input delayed WIPOK and the fact that $T_{\text{WIPOK}} \gg T_{\text{rext}}$ and $T_{\text{WIPOK}} \gg T_{\text{Sign}}$. The latter conditions are required as we're still breaking the signature scheme and the "rewinding secure" extractable commitment.

Equations 49 and 50 follow analogously from the proof in **H₆**.

H₁₃: Identical to **H₁₂** except that we stop breaking the signature scheme and the "rewinding secure" extractable commitment, and start rewinding again to obtain the trapdoor and the adversary's inputs. Note that in this hybrid we're running in **polynomial time** again.

We claim the following

$$v^{12} \approx_c v^{13}. \quad (51)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad W_{k \rightarrow i}^{12} \approx_c W_{k \rightarrow i}^{13}. \quad (52)$$

$$\forall P_k \in \mathcal{P}^{\mathcal{A}}, \forall P_i \in \mathcal{P} \quad \widehat{W}_{k \rightarrow i}^{12} \approx_c \widehat{W}_{k \rightarrow i}^{13}. \quad (53)$$

Equation 51 follows from the fact that this was only a statistical change. For the same reason, equations 52 and 53 and hold.

Hybrid **H₁₃** is identical to our simulator. From the above discussion, we have

$$v^0 \approx_c v^{13}$$

thus proving security of the constructed MPC.

This completes the security proof.

Remark 1 (Three-round NMCOM and complexity-leveraging levels.). *We note that the two-round NM-COM used in our construction can be replaced with a three-round public-coin extractable NMCOM where the non-malleability property holds against man-in-the-middle adversaries running in time $\gg T_f$.*

Further, one could replace the input-delayed WIPOK used in the first three rounds of the protocol with: (1) a two-round public-coin WI proof (i.e., Zap) and, (2) a three-round rewinding-secure extractable commitment where the Zap proves that: either the (three-round) NMCOM contains a valid witness (that

establishes honest behavior in the first three rounds of robust MPC w.r.t. the committed input and randomness) or the rewinding-secure extractable commitment is a commitment to the pre-image of y . Each of these primitives are rewinding-secure, and therefore, with these modifications, we would not need $T_{\text{WIPoK}} \gg T_{\text{extcom}}, T_{\text{Sign}}$, and instead only require that $T_{\text{extcom}}, T_{\text{zap}} \gg T_f$.

Finally, by relying on full rewinding security of the first three rounds of our robust semi-honest MPC (that we do not prove in this manuscript), one can also remove the following levels: $T_{\text{rMPC}_{(1-3)}} \gg T_{\text{nmcom}}, T_{\text{extcom}}, T_{\text{Sign}}$, and instead only rely upon $T_{\text{rMPC}_{(1-3)}} \gg T_f$.
