<sup>2</sup> University of Chinese Academy of Sciences, Beijing, China

Abstract. Automatic search methods have been widely used for cryptanalysis of block ciphers, especially for the most classic cryptanalysis methods – differential and linear cryptanalysis. However, the automatic search methods, no matter based on MILP, SMT/SAT or CP techniques, can be inefficient when the search space is too large. In this paper, we improve Matsui's branch-and-bound search algorithm which is known as the first generic algorithm for finding the best differential and linear trails by proposing three new methods. The three methods, named Reconstructing DDT and LAT According to Weight, Executing Linear Layer Operations in Minimal Cost and Merging Two 4-bit S-boxes into One 8-bit S-box respectively, can efficiently speed up the search process by reducing the search space as much as possible and reducing the cost of executing linear layer operations. We apply our improved algorithm to DESL and GIFT, which are still the hard instances for the automatic search methods. As a result, we find the best differential trails for DESL (up to 14-round) and GIFT-128 (up to 19-round). The best linear trails for DESL (up to 16-round), GIFT-128 (up to 10-round) and GIFT-64 (up to 15-round) are also found. To the best of our knowledge, these security bounds for DESL and GIFT under single-key scenario are given for the first time. Meanwhile, it is the longest exploitable (differential or linear) trails for DESL and GIFT. Furthermore, benefiting from the efficiency of the improved algorithm, we do experiments to demonstrate that the clustering effect of differential trails for 13-round DES and DESL are both weak.

## 1 Introduction

Differential cryptanalysis [5] and linear cryptanalysis [11] are two of the most fundamental methods for cryptanalysis of block ciphers. The first and the most important step of differential cryptanalysis (or linear cryptanalysis) is to find differential trails (or linear trails) with high probabilities (or large correlations). Therefore, how to find effective differential trails or linear trails has become a focus of cryptographer's concern.

At EUROCRYPT'94 [12], Matsui proposed a branch-and-bound depth-first search algorithm, which presents an efficient automatic search algorithm to find the best differential trails and linear trails of DES<sup>3</sup>. However, Matsui's method is not efficient enough for some other block ciphers such as DESL and FEAL. At CRYPTO'95 [14], Moriai et al. improved Matsui's algorithm. They introduced the concept of search patterns to reduce unneccessary search candidates and found the best *n*-round linear trails of FEAL ( $n \leq 32$ ). At FSE'97 [2], Aoki et al. further improved the search algorithm by proposing the pre-search strategy to discard unsatisfiable search patterns. They determined all the best differential trails of FEAL up to 32-round. In [4], Bao et al. proposed three strategies to speed up the search algorithm. They got good results on the best differential and linear trails of NOEKEON and SPONGENT. Bao's three strategies can efficiently speed up the search process. However, it needs quite complex programming skills to implement their strategies.

 $<sup>^{3}</sup>$  Differential trails with highest probability or linear trails with largest correlation are called the best.

The idea of search patterns and the pre-search strategy are hard to implement when the weights<sup>4</sup> of the differential or linear trails of the target cipher are not integers. For example, the weights of the difference propagations of S-boxes in DESL are not all integers. It is not convenient for DESL to perform the pre-search phase, since assigning decimal weights to every single round is difficult. In [2], Aoki et al. provided a version of pre-search algorithm that specially designed for decimal weights, but this algorithm is complicated to implement.

In recent years, Mixed-Integer Linear Programing (MILP) based method has been very popular in constructing automatic search algorithm in differential and linear cryptanalysis [13, 18, 16, 17, 15]. MILP-based method is convenient to programing. But when the block size or the round number of the target cipher is large, the size of the corresponding MILP model will be too large. There are some papers [20, 10] using MILP-based method to study the security of GIFT-128. But they can only get differential trails under some limitations and they cannot estimate the best difference propagation probabilities when the round number is large. In [15], Sun et al. applied MILP-based method to search differential trails of DESL, but they can only found a 10-round single-key differential trail of DESL with probability  $2^{-52.25}$ .

The weights of the difference propagations of the S-boxes in DESL and GIFT and the weights of the linear propagations in DESL are not all integers. As mentioned above, the original Matsui's method and the MILP-based method are both not efficient enough to search the best differential trails of DESL or GIFT-128, and it is really complicated to apply the idea of search patterns to accelerate the search process.

#### 1.1 Our Contributions

In this paper, we apply three methods to speed up the original Matsui's algorithm. By these three speeding-up methods, we can efficiently prune unsatisfiable candidates and reduce the cost of executing linear layer operations:

- Reconstructing DDT and LAT According to Weight method is very helpful to reduce the complexity of the search process. We apply this method to prune unsatisfiable candidates by sorting the input and output differences according to their weights.
- Executing Linear Layer Operations in Minimal Cost method can be used to reduce the cost of P permutation and E expansion. By constructing linear layer table and executing look-up-table operations by SSE instructions, we can implement linear layer operations of each round with 2 XOR operations of 128-bit variables.
- Merging Two 4-bit S-boxes into One 8-bit S-box method is used to speed up the search process when the number of S-box is large. In the case of GIFT, by merging two consecutive 4 × 4 S-boxes into one 8 × 8 S-box, we can further reduce the cost of executing linear layer operations.

We use our improved search algorithm to search the best differential trails and linear trails of DES, DESL, GIFT-64 and GIFT-128. The results are helpful for estimating the security of DESL, GIFT-64 and GIFT-128 against differential and linear cryptanalysis.

For DES and DESL, our experimental results<sup>5</sup> presented in Table 3 show that the first two methods bring an acceleration by a factor of 26-173. For GIFT-64 and GIFT-128, our experimental results presented in Table 4 show that the third method brings an acceleration by a factor of 2-4.

#### **Results on DES and DESL:**

- For DES. We find the best differential trails for up to 18-round<sup>6</sup>. The best difference probability of 18-round DES is  $2^{-69.84}$ . The results are summarized in Table 3. We find the best linear trails

<sup>&</sup>lt;sup>4</sup> We refer readers to [7] for the definition of the weight of difference (or linear) propagation and the weight of differential (or linear) trail.

<sup>&</sup>lt;sup>5</sup> All of the experiments and results in this paper are obtained and timed on a PC with Intel(R) Core(TM) i7-6700 3.40 GHz CPU, and 16 GB RAM, using single-thread program in C.

<sup>&</sup>lt;sup>6</sup> The round number of DES is 16.

of DES for up to 22-round. The best linear correlation of 22-round DES is  $2^{-32.46}$ . The results are summarized in Table 5.

We confirm the results on the best difference and linear probability of DES provided in [12, 14]. As we can see from Table 3, our new methods can efficiently speed up the search process.

- For DESL. We find the best differential trails for up to 14-round. The best difference probability of 14-round DESL is  $2^{-68.78}$ . The results are summarized in Table 3. We find the best linear trails of DESL for up to 16-round. The best linear correlation of 16-round DESL is  $2^{-32.98}$ . The results are summarized in Table 5.

To the best of our knowledge, we find the longest exploitable best differential and linear trails for DESL. In [16], the authors found a 10-round differential trail with probability  $2^{-52.25}$ , and there is no previous results on linear trails of DESL.

 Demonstrating the Clustering Effect. In [7], it has been mentioned that the differential and linear clustering effect of DES are both weak. But no experimental result was provided to demonstrate this conclusion.

In this paper, we conduct experiments applying the improved Matsui's algorithm to search the clustering effect of differential trails for 13-round DES and DESL. Through the experiments in Sect.7, we find that the clustering effect of differential trails for 13-round DES and DESL are both weak.

## **Results on GIFT:**

- For GIFT-64. We find the best differential trails for up to 14-round. The best difference probability of 14-round GIFT-64 is 2<sup>-68.000</sup>. The results are summarized in Table 4. We find the best linear trails of GIFT-64 for up to 15-round. The best linear correlation of 13-round GIFT-64 is 2<sup>34.00</sup>. The results are summarized in Table 6.

We find the longest exploitable best linear trails of GIFT-64 and we confirm the results on the best difference probability of GIFT-64 provided in [19].

- For GIFT-128. We find the best differential trails for up to 19-round. The best difference probability of 19-round GIFT-128 is 2<sup>-110.830</sup>. The results are summarized in Table 4.
We find the best linear trails of CIET 128 for up to 10 more d. The best linear completion of

We find the best linear trails of GIFT-128 for up to 10-round. The best linear correlation of 10-round GIFT-128 is  $2^{-26.00}$ . The results are summarized in Table 6.

We find the longest exploitable best differential and linear trails for GIFT-128. The results on the best difference probabilities and best linear correlations provided in this paper are the tightest security bounds of GIFT-128, which are found for the first time.

To illustrate the efficiency of our improved algorithm, we compare our results on the weight of the best differential trails with previous work in Table 1.

We find no result on the best linear trails of DESL or GIFT from previous work. Since the weights of the linear propagations of S-boxes in GIFT are integers, Bao's algorithm can be very suitable to search the best linear trails of GIFT. We compare our results on the weight of the best linear trails with the results of Bao's algorithm in Table 2.

As shown in Table 2, for SPN block ciphers, when the weights are all integers, Bao's algorithm is more efficient than our improved Matsui's algorithm. But we need to state that: The improved Matsui's algorithm in this paper is easier to implement, and is more convenient to be applied in situations when the weights are not all integers.

In addition, the improved Matsui's algorithm can be used to search the best differential trails and best linear trails for other primitives, estimate the clustering effect and search the multiple differential distinguishers or multi-dimensional linear distinguishers.

#### 1.2 Organization

The paper is organized as follows. Some preliminaries and symbolic conventions are presented in Sect.2. We introduce the four block ciphers: DES, DESL, GIFT-64 and GIFT-128 and Matsui's search algorithm in Sect.3. In Sect.4, we propose our three speeding-up methods. Sect.5 and Sect.6 give the experimental results on the best differential and linear trails of DES, DESL, and GIFT,

providing justification for the efficiency of the three speeding-up methods. Sect.7 gives experimental results on estimating the clustering effect of differential trails for 13-round DES and DESL. Sect.8 is the conclusion and discussion.

## 2 Notations and Preliminaries

In [12], Matsui illustrated the duality between differential cryptanalysis and linear cryptanalysis. In this paper, we take differential cryptanalysis as an example to explain our speeding-up methods. The notations we use are similar to those in [12]. We use the sum of the weights of the round differential trails to characterize the best differential trails.

 $X_i, Y_i$ : the input and the output of the round function  $F_i$ 

 $X_i^t, Y_i^t$ : the input and the output of the *t*-th S-box

 $\Delta X_i, \Delta Y_i, \Delta X_i^t, \Delta Y_i^t$ : the differential value of  $X_i, Y_i, X_i^t$  and  $Y_i^t$ 

 $\varGamma X_i, \varGamma Y_i$  : the masking value of  $X_i$  and  $Y_i$ 

 $K_i$ : the round key of the round function  $F_i$ 

 $\oplus$  ,  $\bullet$  : the bitwise XOR operation and AND operation

P(x): P permutation on 0-1 string x

 $E \circ P(x)$ : composition of P permutation and E expansion on 0-1 string x

 $parity(x) \stackrel{def}{=} x_0 \oplus x_1 \oplus \cdots \oplus x_{n-1}$ , in which  $x = x_0 ||x_1|| \cdots ||x_{n-1}|$  is 0-1 string

In the case of **differential cryptanalysis**, we calculate the weights of the difference propagation probabilities:

$$\begin{split} & (\Delta X_i, \Delta Y_i) \stackrel{def}{=} -log_2^{Prob}\{F_i(X_i \oplus \Delta X_i, K_i) = F_i(X_i, K_i) \oplus \Delta Y_i\} \\ & [w_1, w_2, \cdots, w_l] \stackrel{def}{=} \sum_{i=1}^t w_i \\ & B_n \stackrel{def}{=} \min[(\Delta X_1, \Delta Y_1), (\Delta X_2, \Delta Y_2), \cdots, (\Delta X_n, \Delta Y_n)] \\ & \text{Note:} \\ & \Delta X_i = \Delta X_{i-2} \oplus E \circ P(\Delta Y_{i-1}), 3 \leq i \leq n, \text{ in the case of DES and DESL}; \\ & \Delta X_i = P(\Delta Y_{i-1}), 2 \leq i \leq n, \text{ in the case of GIFT.} \\ & \text{In the case of linear cryptanalysis, we calculate the weights of the linear correlations:} \\ & (\Gamma X_i, \Gamma Y_i) \stackrel{def}{=} -log_2^{|Prob}\{parity(X_i \bullet \Gamma X_i) = parity(F_i(X_i, K_i) \bullet \Gamma Y_i)\} - 1/2| - 1 \\ & [w_1, w_2, \cdots, w_l] \stackrel{def}{=} \sum_{i=1}^t w_i \\ & B_n \stackrel{def}{=} \min[(\Gamma X_1, \Gamma Y_1), (\Gamma X_2, \Gamma Y_2), \cdots, (\Gamma X_n, \Gamma Y_n)] \\ & \text{Note:} \\ & \Gamma Y_i = \Gamma Y_{i-2} \oplus E \circ P(\Gamma X_{i-1}), 3 \leq i \leq n, \text{ in the case of DES and DESL}; \\ & \Gamma X_i = P(\Gamma Y_{i-1}), 2 \leq i \leq n, \text{ in the case of GIFT.} \end{split}$$

## 3 Related Work

## 3.1 Feistel Block Cipher DES

The Data Encryption Standard [8] (DES) was developed at IBM and adopted by the U.S. National Bureau of Standards as the standard cryptosystem for sensitive but unclassified data. DES is a Feistel structure block cipher whose block size is 64 bits and key size is 56 bits. The round number of DES is 16. We illustrate the Feistel structure and the round function of DES in Fig.1. We refer readers to [8] for more details of DES.

- There are 8 different S-boxes in DES. We denote them as  $S_i, 1 \le i \le 8$ . For each S-box, it takes an input of 6 bits and gives an output of 4 bits.
- E is a bitwise expansion. It takes an input of 32 bits and gives an output of 48 bits. P is a bitwise
  permutation. It takes an input of 32 bits and gives an output of 32 bits.

#### 3.2 Feistel Block Cipher DESL

DESL [9] is a lightweight variant of DES. DESL is almost the same as DES, except that it uses a single S-box instead of 8 different S-boxes as DES. The designers adapted the DES S-box design criteria and proposed the S-box used in DESL. Using the well designed S-box, DESL is stronger than DES in resisting differential and linear cryptanalysis. We refer readers to [9] for more details of DESL.

#### 3.3 SPN Block Cipher GIFT

GIFT [3] is an SP-network lightweight block cipher. GIFT has two versions named in GIFT-64 and GIFT-128, whose block sizes are 64 and 128 bits respectively, and round numbers are 28 and 40 respectively. The key length of GIFT-64 and GIFT-128 are both 128 bits.

Recently, Banik et al. proposed a lightweight Authenticated Encryption (AE) scheme GIFT-COFB based on GIFT-128, which is one of the Round 1 Candidates of NIST Lightweight Crypto Standardization process [1].

There are 32 same  $4 \times 4$  S-boxes in GIFT-128 and 16 same  $4 \times 4$  S-boxes in GIFT-64. The round function of GIFT-128 is shown in Fig.2. We refer readers to [3] for more details of GIFT.

## 3.4 Matsui's Search Algorithm

Matsui's algorithm works by induction on the number of rounds and derives the best *n*-round weight  $B_n$  from the knowledge of all *i*-round best weight  $B_i$   $(1 \le i \le n-1)$ . The program requires an initial value for  $B_n$ , which is represented as  $Bc_n$ . It works correctly for any  $Bc_i$  as long as  $Bc_i \ge B_i$   $(1 \le i \le n-1)$ .

The original search algorithm is recursive and targets DES. Alg.1 and Alg.2 show the details of Matsui's search algorithm targets Feistel cipher and SPN cipher respectively.

## 4 Our New Speeding-up Methods

**Overall Strategy** In order to speed up Matsui's search algorithm, we need to further study the inner details of Matsui's algorithm and the objective block ciphers: DES, DESL, GIFT.

9

We speed up the search process in the following two ways:

- 1 As mentioned in [14], the complexity of the search process for the *n*-round best trails is dominated by the number of candidates in Procedure Round-1 and Procedure Round-2. We apply the speeding-up method in Sect.4.1 to prune unsatisfiable candidates as soon as we can;
- 2 When we get a new candidate of  $\Delta Y_i$ , we need to calculate  $E \circ P(\Delta Y_i)$  or  $P(\Delta Y_i)$ . We apply the speeding-up methods in Sect.4.2 and Sect.4.3 to reduce the cost of executing linear layer operations.

## 4.1 Reconstructing DDT and LAT According to Weight

We take Alg.1 and DES as an example to illustrate how to construct new look-up tables. Alg.1 is a branch-and-bound algorithm, pruning unsatisfiable candidates by the inequalities set in each round. In [12], Matsui suggested that we should try  $\Delta X_i^j$  and  $\Delta Y_i^j$  in order of the magnitude of  $(\Delta X_i^j, \Delta Y_i^j)$ . In [4], Bao et al. also searched  $\Delta X_i^j$  and  $\Delta Y_i^j$  in order of their weights. Inspired by their ideas, we reconstruct the difference distribution table in Procedure Round-1, Round-2 and Round-*i*  $(3 \le i \le n-1)$  respectively, ranking input-output difference pairs in order of their weights. With the help of the new look-up tables, we can efficiently search the input-output difference pairs with large weights and throw away input-output difference pairs with small weights as soon as possible. By doing this, we can significantly accelerate the search process.

There are 9 different weights of the difference propagations for each S-box in DES: 5.00, 4.00, 3.42, 3.00, 2.68, 2.42, 2.20, 2.00, 0.00. We use a table to denote this weight set. The elements are sorted in a descending order:

WeightTable[9]={5.00, 4.00, 3.42, 3.00, 2.68, 2.42, 2.20, 2.00, 0.00}

In Procedure Round-1 Since the output difference has no effect on the subsequent search process, we only care about the input difference and their weights. We construct one table to classify the input differences of each S-box according to the corresponding weights:

DDTwX[SboxN][WeightN][InN]

- SboxN represents the index of the S-box. It ranges from 1 to 8. WeightN represents the index of the weights. It ranges from 0 to 8. InN represents the index of the input difference. It ranges from 0 to 63.
- DDTwX[t][j][r] represents the r-th input difference of the t-th S-box with a weight Weight Table[j].

In Procedure Round-2 We care about the input-output difference pairs and their weights. We construct two tables:

DDTXorder[SboxN][WeightN][InN] DDTYorder[SboxN][WeightN][OutN]

- InN represents the index of the input difference. OutN represents the index of the output difference. The range of these two values depends on the choice of the S-box. For DES, InN and OutN range from 0 to 267 respectively.
- DDTXorder[t][j][r] represents the r-th input difference of the t-th S-box with a weight WeightTable[j]. Its corresponding output difference is DDTYorder[t][j][r].

In Procedure Round-*i*,  $3 \le i \le n-1$ . Since the input difference is fixed, we care about the corresponding output differences and their weights. We construct two tables:

 InV represents the value of the input difference. It ranges from 0 to 63. OutN represents the index of the output difference. It ranges from 0 to 15.

- DDTY[i][j][r] represents the *r*-th output difference of the *i*-th S-box whose input difference is *j*. Its corresponding weight is DDTYw[i][j][r].
- We rank the output differences of each input difference in order of their weights: if  $r_1 < r_2$ , then  $DDTYw[i][j][r_1] \leq DDTYw[i][j][r_2]$ .

The accelerated Procedure Round-i,  $1 \le i \le n-1$  using new look-up tables is shown in Alg.3. We omit the constraints between the the input differences of adjacent S-boxes in Alg.3.

In Procedure Round-1. For the *t*-th S-box, we traverse the weights of its difference propagations from WeightTable[8] to WeightTable[0]. If WeightTable[j] does not satisfy the inequality:

$$[w_1, B_{n-1}] \le Bc_n \tag{1}$$

then we can prune the input differences with weights range from WeightTable[j] to WeightTable[0].

In Procedure Round-2. For the *t*-th S-box, we traverse its weights from WeightTable[8] to WeightTable[0]. For each satisfiable WeightTable[j], we traverse the corresponding input differences and output differences.

In Procedure Round-*i*,  $3 \le i \le n-1$ . For the *t*-th S-box, its input difference is  $\Delta X_i^t$ . We traverse its weights in the order: DDTYw[*t*][ $\Delta X_i^t$ ][0], DDTYw[*t*][ $\Delta X_i^t$ ][1],  $\cdots$  and the corresponding output differences. If DDTYw[*t*][ $\Delta X_i^t$ ][j] does not satisfy the inequality:

$$[w_1, w_2, \cdots, w_i, B_{n-i}] \ge Bc_n \tag{2}$$

then we don't need to traverse DDTYw $[t][\Delta X_i^t][m] \ (m \ge j)$ .

#### 4.2 Executing Linear Layer Operations in Minimal Cost

We take Alg.3 and DES as an example. The implementation of P and E operations is one of the most costly parts of the search process. Since it is efficient to execute linear layer operations by looking up tables, we construct one table to execute the P permutation and the E expansion at once. Taking advantage of the new table, we can easily use SSE instructions to implement linear layer operations.

In [4], Bao et al. proposed a speeding-up method named *Trailing in Minimal Changes Order Strategy.* They constructed one table to implement nonlinear layer and linear layer operations at once. Inspired by this method, we build one linear-layer table according to the output differences of each S-box. The new table is:

### EPtable[SboxN][OutV][LocN]

- In order to use SSE instructions, we split the output of  $E \circ P(\cdot)$  into eight 4-bit values. SboxN represents the index of the S-box. It ranges from 1 to 8. OutV represents the value of the output difference. It ranges from 0 to 15. LocN represents the index of the output after executing P and E operations. It ranges from 0 to 7.
- EPtable[t][j][r] represents that: for the t-th S-box whose output difference is j, after executing the P permutation and the E expansion, the r-th value of the output is EPtable[t][j][r].

With the help of EPtable[SboxN][OutV][LocN] table, we can reduce the cost of executing P and E operations from 7 XOR operations to 2 XOR operations.

- In general, we look up the EPtable[SboxN][OutV][LocN] table to determine the value of  $E \circ P(\Delta Y_i)$  when we generate a new value of  $\Delta Y_i$ . We use the SSE instructions to execute the look-up-table operations. To generate the value of  $E \circ P(\Delta Y_i)$ , we need to perform **7 XOR operations of 128-bit variables**.
- We find that when we traverse the output difference of the *r*-th S-box of the *i*-th round, the only difference between the new output difference value  $\Delta Y_{inew}$  and the old output difference value  $\Delta Y_{iold}$  is  $\Delta Y_i^r$ . So we can calculate  $E \circ P(\Delta Y_{inew})$  using  $E \circ P(\Delta Y_{iold})$  and EPt-able[SboxN][OutV][LocN]. Then we only need to perform **2 XOR operations of 128-bit variables** to generate the value of  $E \circ P(\Delta Y_{inew})$ .

The speeding-up methods presented in Sect.4.1 and Sect.4.2 are also applied in the search process of GIFT. The improved search approach is shown in Alg.4<sup>7</sup>.

Algorithm 4: Our Search Approach for GIFT

 $n \geq 3$ ;  $B_1, B_2, \cdots, B_{n-1}$ ;  $Bc_n$ ; WeightTable[10]; NofSbox. Input: **Output**:  $B_n = Bc_n$ ; the best differential trails of *n*-round. 1 Generate Tables DDTwY[SboxN][WeightN][InN];  $\mathbf{2}$ DDTY[SboxN][InV][OutN], DDTYw[SboxN][InV][OutN]; 3 Ptable[SboxN][OutV][LocN]; 4 5 end 6 Procedure Round-1  $w_1 \leftarrow 0, \Delta Y_1 \leftarrow 0;$ 7 for t=1 to NofSbox do 8 for j = 9 to  $\theta$  do 9  $w_1 \leftarrow w_1 + WeightTable[j];$ 10 if  $[w_1, B_{n-1}] \ge Bc_n$  then break; 11 else for each DDTwY[t][j][r] do 12 $\Delta Y_1^t \leftarrow DDTwY[t][j][r], \text{ call Round-2}$ 13 end 14 end 15 $\mathbf{end}$ 16 end 17 **Procedure** Round- $i, 2 \le i \le n-1$ 18  $\Delta X_i \leftarrow P(\Delta Y_{i-1});$ 19  $w_i \leftarrow DDTYw[1][\Delta X_i^1][0] + \dots + DDTYw[NofSbox][\Delta X_i^{NofSbox}][0];$ 20  $\Delta Y_i^1 \leftarrow DDTY[1][\Delta X_i^1][0], \cdots, \Delta Y_i^{NofSbox} \leftarrow DDTY[NofSbox][\Delta X_i^{NofSbox}][0];$ 21 for t=1 to NofSbox do 22  $w_i \leftarrow w_i - DDTYw[t][\Delta X_i^t][0];$ 23 for each  $DDTYw[t][\Delta X_i^t][r]$  do 24  $w_i \leftarrow w_i + DDTYw[t][\Delta X_i^t][r];$  $\mathbf{25}$ if  $[w_1, \cdots, w_i, B_{n-i}] \geq Bc_n$  then break; 26 else  $\Delta Y_i^t \leftarrow DDTY[t][\Delta X_i^t][r]$ , call Round-(i+1)27 end 28 end 29 30 end **Procedure** Round-*n* 31  $\Delta X_n \leftarrow P(\Delta Y_{n-1}), w_n \leftarrow min_{\Delta Y_n}(\Delta X_n, \Delta Y_n);$ 32 if  $[w_1, w_2, \cdots, w_n] \leq Bc_n$  then  $Bc_n = [w_1, w_2, \cdots, w_n];$ 33 return to the upper procedure; 34 35 end

Compared with Alg.3, there are two new tables in Alg.4: DDTwY[SboxN][WeightN][OutN] Ptable[SboxN][OutV][LocN]

- DDTwY[t][j][r] represents the r-th output difference of the t-th S-box with a weight WeightTable[j].

- We split the output of  $P(\cdot)$  into sixteen 8-bit values. LocN represents the index of the output after executing the P permutation. It ranges from 0 to 15.

<sup>&</sup>lt;sup>7</sup> NofSbox represents the number of the S-boxes. For GIFT-128, NofSbox = 16; for GIFT-64, NofSbox = 8.

- Ptable[t][j][r] represents that: for the *t*-th S-box whose output difference is *j*, after executing the P permutation, the *r*-th value of the output is Ptable[t][j][r].

#### 4.3 Merging Two 4-bit S-boxes into One 8-bit S-box

We take GIFT-128 as an example. There are  $32.4 \times 4$  S-boxes in GIFT-128. To speed up the search process, we merge the two consecutive  $4 \times 4$  S-boxes into one  $8 \times 8$  S-box. The original 32 S-boxes of GIFT-128 is as follows:

$$S_1, S_2, S_3, \cdots, S_{31}, S_{32}$$
 (3)

We mark the original version of GIFT-128 as the **old-version GIFT-128**. There are  $16.8 \times 8$  S-boxes in the **new-version GIFT-128**:

$$SS_1, SS_2, SS_3, \cdots, SS_{15}, SS_{16}$$
 (4)

The relationship between  $S_1, S_2, \dots, S_{32}$  and  $SS_1, SS_2, \dots, SS_{16}$  is that, if we have:

$$Y^{2 \cdot i - 1} = S_{2 \cdot i - 1} [X^{2 \cdot i - 1}] \tag{5}$$

$$Y^{2 \cdot i} = S_{2 \cdot i}[X^{2 \cdot i}], \tag{6}$$

then we have:

$$Y^{2 \cdot i - 1} || Y^{2 \cdot i} = SS_i [X^{2 \cdot i - 1} || X^{2 \cdot i}]$$
(7)

in which  $1 \le i \le 16$ .

Using this speeding-up method, we can efficiently speed up the search process of GIFT-128:

- 1 It is very convenient to store sixteen 8-bit value with a 128-bit variable, so we can easily use SSE instructions just as in Alg.3;
- 2 The cost of executing the P permutation can be reduced. For example, if the output difference of  $SS_r$  changes from 0x12 to 0x35, then we only need 2 XOR operations  $(0x12 \rightarrow 0x35)$  of 128-bit variables to generate  $P(\Delta Y)$ . While in the search of the old-version GIFT-128, we need 4 XOR operations  $(0x1 \rightarrow 0x3, 0x2 \rightarrow 0x5$  respectively) of 128-bit variables.

## 5 Experimental Results on Best Differential Trails

## 5.1 DES and DESL

We have searched the best differential trails and the weights of the best differential trails of DES and DESL with Alg.3. Table 3 summarizes our experimental results. Table 14 in Appendix A shows one of the best 12-round differential trails of DESL.

## 5.2 GIFT

We have searched the best differential trails and the weights of the best differential trails of GIFT-64 and GIFT-128 with Alg.4. Table 4 summarizes our experimental results. Table 15 in Appendix A shows one of the best 19-round differential trails of GIFT-128. Table 16 in Appendix A shows one of the best 14-round differential trails of GIFT-64.

## 6 Experimental Results on Best Linear Trails

## 6.1 DES and DESL

We have searched the best linear trails and the weights of the best linear trails of DES and DESL with the variant of Alg.3<sup>8</sup>. Table 5 summarizes our experimental results. Table 14 in Appendix A shows one of the best 16-round linear trails of DESL.

 $<sup>^{8}</sup>$  We refer readers to [12] to get the transformation method.

Table 3. The weights of the best differential trails of DES and DESL

<sup>1</sup> n: the round number.  $B_n$ : the weight of the best differential trails of n-round.  $Bc_n$ : the initial value of  $B_n$ .

 $^2 \ t_0$  : the search time of the original Matsui's method (Alg.1).

 $^3\,t_1$  : the search time of applying the speeding-up method in Sect.4.1.

 $^4 t_2$  : the search time of applying the speeding-up methods in Sect.4.1 and Sect.4.2.

## 6.2 GIFT

We have searched the best linear trails and the weights of the best linear trails of GIFT-64 and GIFT-128 with the variant of Alg.4. Table 6 summarizes our experimental results. Table 15 in Appendix A shows one of the best 10-round linear trails of GIFT-128. Table 16 in Appendix A shows one of the best 13-round linear trails of GIFT-64.

## 7 Experimental Results on Estimating the Differential Clustering Effect of DES and DESL

Let PD denote the plaintext difference and CD denote the ciphertext difference. Let  $Bu_n$  denote the upper bound of  $B_n$ . In all the experiments of Sect.7, we try to find all the differential trails with weights  $B_n$  satisfying  $B_n \leq Bu_n$ .

### 7.1 DES

In [6], Biham et al. proposed a key recovery attack on 16-round DES using a 13-round differential trail with weight 47.22. In Sect.7.1, we estimate the clustering effect of differential trails for 13-round DES based on Alg.3. We focus on PD, CD and the weights of the differential trails.

**Experiment 1** The 13-round differential trail used in [6] is as follows<sup>9</sup>:

$$PD = 19600000\ 00000000,\ CD = 19600000\ 00000000 \tag{8}$$

First of all, we try to find different differential trails satisfying equation (12). Table 7 summarizes the experimental results.

We set  $Bu_{13} = 65$ , but there is still only one differential trail satisfying equation (8). Therefore, the clustering effect of differential trail satisfying equation (8) is weak.

<sup>&</sup>lt;sup>9</sup> All the plaintext differences and ciphertext differences given below are in hexadecimal form.

Table 6. The weights of the best linear trails of GIFT

 $^{1}$  t1 : the search time of applying the speeding-up methods in Sect.4.1, Sect.4.2 and Sect.4.3.

Table	7.	Results	of	Experiment	1
-------	----	---------	----	------------	---

	paramet	result	s	
$Bu_{13}$	PD	number of trails	search time	
65	19600000 00000000	19600000 00000000	1	2.81h

**Experiment 2** We try to find other 13-round differential trails with small weight and strong clustering effect, and we hope to find 13-round differential hulls with weight smaller than 47.22.

We increase the value of  $Bu_{13}$  and count the number of differential trails with weight satisfying  $B_{13} \leq Bu_{13}$ . Table 8 summarizes the experimental results.

**Table 8.** Results of Experiment 2

parameters		results		
Dat	number of trails	number of trails with the same	search time	
$Bu_{13}$	number of trans	plaintext and ciphertext difference		
51	55	0	2.17m	
52	203	0	11.69m	
53	531	0	81.17m	

As we can see from Table 8, setting  $Bu_{13} = 53$ , we get 531 differential trails, but there is still no two trails sharing the same PD and CD.

**Experiment 3** In Experiment 2, setting  $Bu_{13} = 51$ , we get 55 differential trails. Among the 55 trails, there are four trails with weights smaller than 50. The *PD* and *CD* of these four trails are shown in Table 9.

Similar to Experiment 1, we explore the clustering effect of the differential trail No.2 to No.4. Table 10 summarizes the experimental results. Setting  $Bu_{13} = 56$ , we still cannot find new differential trails sharing the same PD and CD with differential trail No.2, No.3 or No.4 in Table 9.

The experimental results of Experiment 1 to 3 show that the clustering effect of differential trails for 13-round DES is weak.

number	PD	CD	weight
1	19600000 00000000	19600000 00000000	47.22
2	1b600000 00000000	1b600000 00000000	47.22
3	00196000 00000000	00196000 00000000	48.00
4	$000003d4 \ 00000000$	$000003d4 \ 00000000$	48.56

 Table 9. Four differential trails with the smallest weights of 13-round DES

Table 10.	Results of Experiment 3	

	paramet	result	s		
$Bu_{13}$	PD	PD CD		number of trails search time	
56	1b600000 00000000	1b600000 00000000	1	8.53s	
56	00196000 00000000	00196000 00000000	1	10.03s	
56	$000003d4 \ 00000000$	$000003d4 \ 00000000$	1	7.28s	

## 7.2 DESL

As we can see from Table 3, the weight of 12-round best differential trails of DESL is 58.10, which is larger than the key size 56. In order to construct 16-round key recovery attack on DESL, we estimate the differential clustering effect of 13-round DESL.

**Experiment 4** We try to find 13-round differential trails with small propagation weight and strong clustering effect. Hopefully, we want to find 13-round differential hulls with weight smaller than 56.

We increase the value of  $Bu_{13}$  and count the number of differential trails with weight satisfying  $B_{13} \leq Bu_{13}$ . Table 11 summarizes the experimental results.

parameters		results	
$Bu_{13}$	number of trails	search time	
62	52	0	16.78s
63	214	0	73.40s
65	1137	0	1277.17s

Table 11. Results of Experiment 4

Through Experiment 4, we cannot find two trails having the same PD and CD. We get two trails with weight 60.78 and 16 trails with weight 61.37<sup>10</sup>. The PD and CD of these trails are shown in Table  $12^{11}$ .

**Experiment 5** We explore the clustering effect of differential trails in Table 12. Table 13 summarizes the experimental results.

We set  $Bu_{13} = 70$ , and set the value of PD and CD same as the No.1 trail in Table 12:

$$PD = 027c0400\ 00000040,\ CD = 027a0400\ 00000040 \tag{9}$$

We find three trails satisfying equation (9). The weight of these three trails are: 65.17, 67.56 and 60.78.

As we can see from Table 13, we get one differential hull with weight 60.70 and eight differential hulls with weight 61.29. These differential hulls are useless for 16-round key recovery attack of DESL.

The experimental results of Experiment 4 and 5 show that **the clustering effect of differential trails for 13-round DESL is weak**.

 $^{10}$  61.37 is the second smallest weight of 13-round DESL differential trails.

<sup>11</sup> Considering the symmetry of encryption and decryption process of DESL, there are actually one trail with weight 60.78 and 8 trails with weight 61.37.

$B_{13}$	number	PD	CD
60.78	1	$027c0400 \ 00000040$	$027a0400 \ 00000040$
61.37	2	027a0401 00000040	027c0400 00000040
61.37	3	$027c0400 \ 00000040$	$026a0400 \ 00000040$
61.37	4	$027c0400 \ 00000040$	$007a0400 \ 00000040$
61.37	5	$027c0400 \ 00000040$	$007a0401 \ 00000040$
61.37	6	$027a0400 \ 00000040$	026c0400 00000040
61.37	7	$027a0400 \ 00000040$	007c0401 00000040
61.37	8	027a0400 00000040	027c0401 00000040
61.37	9	$007c0400 \ 00000040$	$027a0400 \ 00000040$

 Table 12. Nine differential trails with the smallest weights of 13-round DESL

Table 13. Results of Experiment 5

parameters		results				
$Bu_{13}$	number in Table 12	number of trails	sum of weights	search time		
70	1	3	60.70	1141.01s		
70	2	3	61.29	333.46s		
70	3	3	61.29	1142.66s		
70	4	3	61.29	1144.72s		
70	5	3	61.29	1139.02s		
70	6	3	61.29	601.44s		
70	7	3	61.29	594.18s		
70	8	3	61.29	602.26s		
70	9	3	61.29	624.57s		

<sup>1</sup> Set the value of PD and CD according to Table 12.

## 8 Conclusion and Future Work

In this paper, we improve Matsui's search algorithm of searching the best differential and linear trails by applying three new speeding-up methods. The key idea of our speeding-up methods is to prune unsatisfiable candidates as soon as we can and to decrease the cost of linear layer operations. With the help of the improved algorithm, we find the best differential and linear trails of Feistel block cipher DESL and SPN block cipher GIFT-128 and GIFT-64. We also estimate that the clustering effect of differential trails for 13-round DES and DESL are both weak.

In the end, we would like to propose some problems deserving further investigation.

- As shown in Table 4, our improved search algorithm is not efficient enough to find the best differential trails for GIFT-128 when  $n \ge 19$ . It is because that when the value of  $Bc_n B_{n-1}$  is large, there would be too many candidates. We hope to find some ways to prune unsatisfiable candidates more efficiently.
- Speeding-up methods proposed in this paper are also helpful in searching related-key differential distinguishers. We hope to apply our methods to the case of related-key differential cryptanalysis.
