#### Abstract

In (TCC 2017), Hofheinz, Hövelmanns and Kiltz provided a fine-grained and modular toolkit of generic key encapsulation mechanism (KEM) constructions, which were widely used among KEM submissions to NIST Post-Quantum Cryptography Standardization project. The security of these generic constructions in the quantum random oracle model (QROM) has been analyzed by Hofheinz, Hövelmanns and Kiltz (TCC 2017), Saito, Xagawa and Yamakawa (Eurocrypt 2018), and Jiang et al. (Crypto 2018). However, the security proofs from standard assumptions are far from tight. In particular, the factor of security loss is $q$ and the degree of security loss is 2 , where $q$ is the total number of adversarial queries to various oracles. In this paper, using semi-classical oracle technique recently introduced by Ambainis, Hamburg and Unruh (ePrint 2018/904), we improve the results in (Eurocrypt 2018, Crypto 2018) and provide tighter security proofs for generic KEM constructions from standard assumptions. More precisely, the factor of security loss $q$ is reduced to be $\sqrt{q}$. In addition, for transformation T that turns a probabilistic public-key encryption (PKE) into a determined one by derandomization and re-encryption, the degree of security loss 2 is reduced to be 1 . Our tighter security proofs can give more confidence to NIST KEM submissions where these generic transformations are used, e.g., CRYSTALS-Kyber etc.

Keywords: quantum random oracle model • key encapsulation mechanism • generic construction

## 1 Introduction

Indistinguishability against chosen-ciphertext attacks (IND-CCA) [1] is widely accepted as a standard security notion for a key encapsulation mechanism (KEM). Random oracle model (ROM) [2] is an idealized model, where a hash
function is idealized to be a publicly accessible random oracle (RO). Generic constructions of IND-CCA-secure KEMs in the ROM are well studied by Dent [3] and Hofheinz, Hövelmanns and Kiltz [4]. Essentially, these generic constructions are categorized as variants of Fujisaki-Okamoto (FO) transformation (denote these transformations by FO transformations for brevity) [5, 6], including $\mathrm{FO}^{\perp}, \mathrm{FO}^{\perp}, \mathrm{FO}_{m}^{\perp}, \mathrm{FO}_{m}^{\perp}, \mathrm{QFO}_{m}^{\perp}$ and $\mathrm{QFO}_{m}^{\perp}$, where $m^{5}$ (without $m$ ) means $K=H(m)(K=H(m, c)), \not \subset(\perp)$ means implicit (explicit) rejection, FO denotes the class of transformations that turn a PKE with standard security (one-wayness against chosen-plaintext attacks (OW-CPA) or indistinguishability against chosen-plaintext attacks (IND-CPA)) into an IND-CCA KEM, Q means an additional Targhi-Unruh hash [7] (a length-preserving hash function that has the same domain and range size) is added into the ciphertext, and variants of REACT/GEM transformation $[8,9]$ (denote these transformations by modular FO transformations), including $\mathrm{U}^{\perp}, \mathrm{U}^{\perp}, \mathrm{U}_{m}^{\perp}, \mathrm{U}_{m}^{\perp}, \mathrm{QU}_{m}^{\perp}$ and $\mathrm{QU}_{m}^{\perp}$, where $U$ denotes the class of transformations that turn a PKE with non-standard security (e.g., OW-PCA, one-way against plaintext checking attack $[8,9]$ ) or a deterministic PKE (DPKE, where the encryption algorithm is deterministic) into an IND-CCA-secure KEM.

Recently, post-quantum security of these generic transformations has gathered great interest [ $4,10-15$ ] due to the widespread adoption [11, Table 1] in KEM submissions to NIST Post-Quantum Cryptography Standardization Project [16], of which the goal is to standardize new public-key cryptographic algorithms with security against quantum adversaries. Quantum adversaries may execute all offline primitives such as hash functions on arbitrary superpositions, which motivated the introduction of quantum random oracle model (QROM) [17]. As Boneh et al. have argued [17], for fully evaluating the post-quantum security, the analysis in the QROM is crucial.

When proving a security of a cryptographic scheme $S$ under a hardness assumption of a problem $P$, we usually construct a reduction algorithm $\mathcal{A}$ against $P$ that uses an adversary $\mathcal{B}$ against $S$ as a subroutine. Let $(T, \epsilon)$ and $\left(T^{\prime}, \epsilon^{\prime}\right)$ denote the running times and advantages of $\mathcal{A}$ and $\mathcal{B}$, respectively. The reduction is said to be tight if $T \approx T^{\prime}$ and $\epsilon \approx \epsilon^{\prime}$. Otherwise, if $T \gg T^{\prime}$ or $\epsilon \ll \epsilon^{\prime}$, the reduction is non-tight. Generally, the tightness gap, (informally) defined by $\frac{T \epsilon^{\prime}}{T^{\prime} \epsilon}[18]$, is used to measure the quality of a reduction. Tighter reductions with smaller tightness gap are desirable for practice cryptography especially in largescale scenarios, since the tightness of a reduction determines the strength of the security guarantees provided by the security proof.

In $[4,10,11]$ and this work, all the security reductions for (modular) FO transformations in the QROM satisfy (1) $T$ is about $T^{\prime}$, i.e., $T \approx T^{\prime} ;(2) \epsilon^{\prime} \approx \kappa \epsilon^{\frac{1}{\tau}}$, where $\kappa$ and $\tau$ in the following are respectively denoted as the factor and degree of security loss ${ }^{6}$. Let $q$ be the total number of adversarial queries to various oracles.

[^0]- In [4], Hofheinz et al. presented QROM security reductions for $\mathrm{QFO}_{m}^{\nless}$ and $\mathrm{QFO}_{m}^{\perp}$ with $\kappa=q^{\frac{3}{2}}$ and $\tau=4$, for $\mathrm{QU}_{m}^{\perp}$ and $\mathrm{QU}_{m}^{\perp}$ with $\kappa=q$ and $\tau=2$.
- In [10], Saito, Xagawa and Yamakawa presented a tight security proof (i.e., $\kappa=1$ and $\tau=1$ ) for $U_{m}^{X}$ under a new (non-standard) security assumption called disjoint simulatability (DS). Moreover, two generic transformation, TPunc and KC, were given to construct a DS-secure DPKE from standard assumptions, with security reductions $\kappa=q$ and $\tau=2$.
- In [11], Jiang et al. presented security reductions for $\mathrm{FO}^{\perp}, \mathrm{FO}_{m}^{\nless}, T, \mathrm{U}^{\not ㇒}, \mathrm{U}^{\perp}$, $\mathrm{U}_{m}^{\perp}$ and $\mathrm{U}_{m}^{\perp}$ with $\kappa=q$ and $\tau=2$.

As seen above, above security proofs of (modular) FO transformations from standard assumptions are far from tight. Recently, To better assess the security of lattice-based submissions, Ducas and Stehlé [19] suggested 10 questions that NIST should be asking the community. The 10 -th question [19, Problem 10] is on this non-tightness in the QROM. To better understand this, they asked that

Can the tightness of those reductions be improved?

### 1.1 Our Contributions

In this paper, we give a positive answer and show that tightness of these reductions can be improved. Specifically, we provide tighter security proofs for these generic transformations in $[4,10]$ by using semi-classical oracle technique recently introduced by Ambainis, Hamburg and Unruh [20]. The improvements of the factor $\kappa$ and the degree $\tau$ of security loss are summarized in Table 1. The detailed comparison with previous results in $[10,11]$ is shown in Table 2, where $\epsilon\left(\epsilon^{\prime}\right)$ is the advantage of an adversary against security of underlying (resulting) cryptographic protimitive and $\delta$ is the correctness error (the probability of decryption failure in a legitimate execution of a scheme).

Table 1: Improvements of the factor $\kappa$ and the degree $\tau$ of security loss.

| $(\kappa, \tau)$ | TPunc, KC | T | $\mathrm{FO}_{m}^{\not}, \mathrm{FO}^{\not}, \mathrm{U} \neq, \mathrm{U}^{\perp}, \mathrm{U}_{m}^{\not}, \mathrm{U}_{m}^{\perp}$ |
| :---: | :---: | :---: | :---: |

| $\mathrm{JZC}^{+} 18[11]$ | - | $(q, 2)$ | $(q, 2)$ |
| Our work | $(\sqrt{q}, 2)$ | $(q, 1)$ | $(\sqrt{q}, 2)$ |

1. For $\mathrm{FO}_{m}^{\not}$ and $\mathrm{FO}^{\not ㇒}$, the security loss factor $q$ in [11] is reduced to be $\sqrt{q}$. Specifically, we give a reduction from IND-CPA security of underlying PKE to IND-CCA security of resulting KEM with $\epsilon^{\prime} \approx \sqrt{q \epsilon}+q \sqrt{\delta}$, which is tighter than $\epsilon^{\prime} \approx q \sqrt{\epsilon}+q \sqrt{\delta}$ in [11] from OW-CPA security of underlying PKE.

Table 2: Comparisons between previous works $[10,11]$ and our work.

2. For T, the quadratic security loss is reduced to be a linear one. Particularly, we provide a reduction from IND-CPA security of underlying PKE to OWqPCA security of resulting PKE with $\epsilon^{\prime} \approx q \epsilon+q \sqrt{\delta}$, while previous reduction in [11] is from OW-CPA security of underlying PKE with $\epsilon^{\prime} \approx q \sqrt{\epsilon}+q \sqrt{\delta}$.
3. For TPunc and KC, the security loss factor $q$ in [10] is reduced to be $\sqrt{q}$. Both IND-CPA security of underlying PKE and OW-CPA of underlying DPKE can be reduced to DS security of DPKE by TPunc and KC with $\epsilon^{\prime} \approx \sqrt{q \epsilon}^{7}$, respectively. While, under the same assumptions, previous reductions [10] are with $\epsilon^{\prime} \approx q \sqrt{\epsilon}$.
4. For $\mathrm{U}^{\perp}, \mathrm{U}^{\perp}, \mathrm{U}_{m}^{\perp}$ and $\mathrm{U}_{m}^{\perp}$, the security loss factor $q$ in [11] is also reduced to $\sqrt{q}$. Particularly, OW-qPCA (one-way against quantum plaintext checking attacks) security and OW-qPVCA (one-way against quantum plaintext and (classical) validity checking attacks) security of underlying PKE, OW-CPA security and OW-VA (one-way against validity checking attacks) security of underlying DPKE can be reduced to IND-CCA security of resulting KEM with $\epsilon^{\prime} \approx \sqrt{q \epsilon+q \delta}$. While, under the same assumptions, previous reductions in [11] are with $\epsilon^{\prime} \approx q \sqrt{\epsilon}$ or $\epsilon^{\prime} \approx q \sqrt{\epsilon}+q \sqrt{\delta}$.
[^1]According to [11, Table 1], our results directly apply to the NIST KEM submissions [16], including CRYSTALS-Kyber, LAC, SABER, SIKE and LEDAkem, and provide tighter reductions than previous known [4, 11]. For the submissions [16] where $\mathrm{QFO}_{m}^{\Varangle}$ and $\mathrm{QFO}^{\perp}$ are adopted, including FrodoKEM, KINDI, Lizard, NewHope, OKCN-AKCN-CNKE, Round2, Titanium, BIG QUAKE and LEDAkem, our results also provide tighter reductions than [11] without requiring the additional Targhi-Unruh hash.

### 1.2 Technique

In security proofs of (modular) FO transformations [4, 11, 10], reprogramming random oracle is an important trick. The security loss in current proofs $[4,11,10]$ arises from the reprogramming of quantum random oracle. Here, we focus on the techniques of improving the analysis of quantum random oracle programming.

One way to hiding (OW2H) lemma [21, Lemma 6.2] is a practical tool to prove the indistinguishability between games where the random oracles are reprogrammed. Roughly speaking, OW2H lemma states that the distinguishing advantage $\left|P_{\text {left }}-P_{\text {right }}\right|$ of an oracle algorithm $A^{\mathcal{O}}$ that issuing at most $q$ queries to an oracle $\mathcal{O}$ distinguishes Left $(\mathcal{O}$ is not reprogrammed) from Right ( $\mathcal{O}$ is reprogrammed at $x^{*}$, can be bounded by $2 q \sqrt{P_{\text {guess }}}$, that is

$$
\begin{equation*}
\left|P_{\text {left }}-P_{\text {right }}\right| \leq 2 q \sqrt{P_{\text {guess }}} \tag{1}
\end{equation*}
$$

where $P_{\text {guess }}$ is the success probability of another oracle algorithm $B$ guessing $x^{*}$ by running $A^{\mathcal{O}}$ and measuring one of $A^{\mathcal{O}}$ 's query uniformly at random. To apply OW2H lemma to prove the security of some certain cryptographic schemes, [11, 10,13 ] generalized the OW2H lemma. However, these generalizations do not give tighter bounds.

Very recently, Ambainis et al. [20] further improved the OW2H lemma by giving higher flexibility as well as tighter bounds. Specifically, a new technique called semi-classical oracle was developed, and semi-classical OW2H lemma was given with tighter bounds. Informally, a semi-classical oracle $\mathcal{O}_{x^{*}}^{S C}$ measures the output $\left|f_{x^{*}}(x)\right\rangle$ instead of $|x\rangle$, where $f_{x^{*}}(x)=1$ if $x=x^{*}$ and 0 otherwise. Let $\mathcal{O} \backslash x^{*}$ be an oracle that first queries semi-classical $\mathcal{O}_{x^{*}}^{S C}$ and then $\mathcal{O}$. Semiclassical OW2H lemma shows that above $\left|P_{\text {left }}-P_{\text {right }}\right|$ can be bounded by $2 \sqrt{q P_{\text {find }}}$, i.e.,

$$
\begin{equation*}
\left|P_{l e f t}-P_{\text {right }}\right| \leq 2 \sqrt{q P_{\text {find }}} \tag{2}
\end{equation*}
$$

where $P_{\text {find }}$ is the probability of the event Find that semi-classical oracle $\mathcal{O}_{x^{*}}^{S C}$ ever outputs 1 during the execution $A^{\mathcal{O} \backslash x^{*}}$.

Next, we show how to use above semi-classical OW2H lemma to improve the security proofs of (modular) FO transformations [11,10]. The primal obstacle is the simulation of the semi-classical oracle $\mathcal{O}_{x^{*}}^{S C}$, which is quantumly accessable. In particular, the key is simulation of $f_{x^{*}}$. We overcome this by making the best of specific properties of different FO-like KEM constructions. Specifically, in security proofs of (modular) FO transformations, $x^{*}$ is instantiated with $m^{*}$ of which the encryption is exactly challenge ciphertext $c^{*}$.

- For KC, $\mathrm{U}_{m}^{\not \supset}$ and $\mathrm{U}_{m}^{\perp}$, underlying PKE is deterministic. $f_{m^{*}}(m)$ can be simulated by verifying whether the encryption of $m$ is $c^{*}$.
- For $U^{\swarrow}$ and $U^{\perp}$, underlying PKE satisfies OW-qPCA security or OWqPVCA security. $f_{m^{*}}(m)$ can be simulated by verifying whether $\operatorname{PCO}\left(m, c^{*}\right)=$ 1 , where $\operatorname{PCO}(m, c)$ is the plaintext checking oracle that returns 1 iff decryption of ciphertext $c$ yields message $m$.
- For TPunc, underlying PKE satisfies IND-CPA security. We note that in IND-CPA security game, $m^{*} \in\left\{m_{0}, m_{1}\right\}$, where $m_{0}$ and $m_{1}$ are chosen by the adversary. Thus, the simulator can simulate $f_{m^{*}}$ by setting $m^{*}=m_{0}$ or $m^{*}=m_{1}$. This trick comes from [20, Sec. 4.2], where Ambainis et al. argued the hardness of inverting a random oracle with leakage.
- For $T, \mathrm{FO}_{m}^{\searrow}, \mathrm{FO}^{\perp}$, OW-CPA security of underlying PKE is assumed in previous security proofs in $[4,11]$, where OW2H lemma is used. When using semi-classical OW2H lemma, we need to a stronger assumption of underlying PKE, IND-CPA security, to follow above mentioned trick to simulate $f_{m^{*}}$.

Directly utilizing semi-classical OW2H lemma with bound (2) instead of OW2H lemma with bound (1), we improve the security reductions for $\mathrm{FO}_{m}^{\not}$, $\mathrm{FO}^{\perp}$, TPunc, $\mathrm{KC}, \mathrm{U}^{\perp}, \mathrm{U}^{\perp}, \mathrm{U}_{m}^{\perp}$ and $\mathrm{U}_{m}^{\perp}$, and reduce security loss factor from $q$ to $\sqrt{q}$.

By introducing Bures distance, Ambainis et al. [20] also gave another tighter bound,

$$
\begin{equation*}
\left|\sqrt{P_{l e f t}}-\sqrt{P_{\text {right }}}\right| \leq 2 \sqrt{q P_{f i n d}} \tag{3}
\end{equation*}
$$

Apparently, as pointed by [20], if $P_{\text {right }}$ is negligible, i.e., $P_{\text {right }} \approx 0$, we can approximately have $\left|P_{\text {left }}\right| \lesssim 4 q P_{\text {find }}$. In the security proofs of (modular) FO transformations, roughly speaking, $P_{\text {left }}$ is the success probability of an adversary against resulting cryptographic scheme, $P_{\text {right }}$ is the corresponding "target probability" (typically, 0 or $1 / 2$ ) specified by concrete security definition, and $P_{\text {find }}$ is the success probability of another adversary against underlying primitive. Note that for OW-qPCA security, the "target probability" $P_{\text {right }}=0$. Thus, using semi-classical OW2H lemma with bound (3), we can further reduce quadratic security loss in the proof of $T$ in [11] to a linear one.

## 2 Preliminaries

Symbol description $\lambda$ is denoted as a security parameter. $\mathcal{K}, \mathcal{M}, \mathcal{C}$ and $\mathcal{R}$ are denoted as key space, message space, ciphertext space and randomness space, respectively. Denote the sampling of a uniformly random element $x$ in a finite set $X$ by $x \stackrel{\$}{\leftarrow} X$. Denote the sampling from some distribution $D$ by $x \leftarrow D$. $x=? y$ is denoted as an integer that is 1 if $x=y$, and otherwise $0 . \operatorname{Pr}[P: G]$ is the probability that the predicate $P$ holds true where free variables in $P$ are assigned according to the program in $G$. Denote deterministic (probabilistic) computation of an algorithm $A$ on input $x$ by $y:=A(x)(y \leftarrow A(x))$. Let $|X|$ be the cardinality of set $X . A^{H}$ means that the algorithm $A$ gets access to the oracle
$H . f \circ g(\cdot)$ means $f(g(\cdot))$. Following the work [4], we also make the convention that the number $q_{H}$ of the adversarial queries to an oracle $H$ counts the total number of times $H$ is executed in the experiment.

Note: All cryptographic primitives and corresponding security and correctness definitions used in this paper are presented in Appendix A.

### 2.1 Quantum Random Oracle Model

In this section, we will present several existing lemmas that we need in our security proofs.

Lemma 1 (Simulating the random oracle [22, Theorem 6.1]). Let $H$ be an oracle drawn from the set of $2 q$-wise independent functions uniformly at random. Then the advantage any quantum algorithm making at most $q$ queries to $H$ has in distinguishing $H$ from a truly random function is identically 0.

Lemma 2 (Generic search problem [23, 24, 11]). Let $\gamma \in[0,1]$. Let $Z$ be a finite set. $F: Z \rightarrow\{0,1\}$ is the following function: For each $z, F(z)=1$ with probability $p_{z}\left(p_{z} \leq \gamma\right)$, and $F(z)=0$ else. Let $N$ be the function with $\forall z: N(z)=0$. If an oracle algorithm $A$ makes at most $q$ quantum queries to $F$ (or $N$ ), then $\left|\operatorname{Pr}\left[b=1: b \leftarrow A^{F}\right]-\operatorname{Pr}\left[b=1: b \leftarrow A^{N}\right]\right| \leq 2 q \sqrt{\gamma}$.

Semi-classical oracle. Roughly speaking, semi-classical oracle $O_{S}^{S C}$ only measures the output $\left|f_{S}(x)\right\rangle$ but not the input $|x\rangle$, where $f_{S}$ is the indicator function such that $f_{S}(x)=1$ if $x \in S$ and 0 otherwise. Formally, for a query to $O_{S}^{S C}$ with $\sum_{x, z} a_{x, z}|x\rangle|z\rangle, \mathcal{O}_{S}^{S C}$ does the following 1. initialize a single qubit $L$ with $|0\rangle$,
2. transform $\sum_{x, z} a_{x, z}|x\rangle|z\rangle|0\rangle$ into $\sum_{x, z} a_{x, z}|x\rangle|z\rangle\left|f_{S}(x)\right\rangle$, 3. measure $L$.

Then, after performing this semi-classical measurement, the query state will become $\sum_{x, z: f_{S}(x)=y} a_{x, z}|x\rangle|z\rangle$ (non-normalized) if the measurement outputs $y(y \in 0,1)$.

Lemma 3 (Semi-classical OW2H [20, Theorem 1]). Let $S \subseteq X$ be random. Let $\mathcal{O}_{1}, \mathcal{O}_{2}$ be oracles with domain $X$ and codomain $Y$ such that $\mathcal{O}_{1}(x)=\mathcal{O}_{2}(x)$ for any $x \notin S$. Let $z$ be a random bitstring. $\left(\mathcal{O}_{1}, \mathcal{O}_{2}, S\right.$ and $z$ may have arbitrary joint distribution D.) Let $\mathcal{O}_{S}^{S C}$ be an oracle that performs the semi-classical measurements corresponding to the projectors $M_{y}$, where $M_{y}:=\sum_{x \in X: f_{S}(x)=y}|x\rangle\langle x|$ $(y \in 0,1)$. Let $\mathcal{O}_{2} \backslash S$ (" $\mathcal{O}_{2}$ punctured on $\left.S "\right)$ be an oracle that first queries $\mathcal{O}_{S}^{S C}$ and then $\mathcal{O}_{2}$. Let $A^{\mathcal{O}_{1}}(z)$ be an oracle algorithm with query depth $q$. Denote Find as the event that in the execution of $A^{\mathcal{O}_{2} \backslash S}(z), \mathcal{O}_{S}^{S C}$ ever outputs 1 during semi-classical measurements. Let

$$
\begin{aligned}
P_{\text {left }} & :=\operatorname{Pr}\left[b=1:\left(\mathcal{O}_{1}, \mathcal{O}_{2}, S, z\right) \leftarrow D, b \leftarrow A^{\mathcal{O}_{1}}(z)\right] \\
P_{\text {right }} & :=\operatorname{Pr}\left[b=1:\left(\mathcal{O}_{1}, \mathcal{O}_{2}, S, z\right) \leftarrow D, b \leftarrow A^{\mathcal{O}_{2}}(z)\right] \\
P_{\text {find }} & :=\operatorname{Pr}\left[\text { Find }:\left(\mathcal{O}_{1}, \mathcal{O}_{2}, S, z\right) \leftarrow D, A^{\mathcal{O}_{2} \backslash S}(z)\right] .
\end{aligned}
$$

Then $\left|P_{\text {left }}-P_{\text {right }}\right| \leq 2 \sqrt{(q+1) P_{\text {find }}}$ and $\left|\sqrt{P_{\text {left }}}-\sqrt{P_{\text {right }}}\right| \leq 2 \sqrt{(q+1) P_{\text {find }}}$. The lemma also holds with bound $\sqrt{(q+1) P_{\text {find }}}$ for alternative definition of $P_{\text {right }}=\operatorname{Pr}\left[b=1 \wedge \neg\right.$ Find $\left.:\left(\mathcal{O}_{1}, \mathcal{O}_{2}, S, z\right) \leftarrow D, b \leftarrow A^{\mathcal{O}_{2} \backslash S}(z)\right]$.

Lemma 4 (Search in semi-classical oracle [20, Corollary 1]). Suppose that $S$ and $z$ are independent, and that $A$ is a q-query algorithm. Let $P_{\max }:=$ $\max _{x \in X} \operatorname{Pr}[x \in S]$. Then $\operatorname{Pr}\left[\right.$ Find $\left.: A^{O_{S}^{S C}}(z)\right] \leq 4 q \cdot P_{\text {max }}$.

## 3 Improved security proofs for (modular) FO transformations

In [4], Hofheinz et al. proposed several (modular) FO transformations, including $\mathrm{T}, \mathrm{U}^{\perp}, \mathrm{U}^{\perp}, \mathrm{U}_{m}^{\perp}, \mathrm{U}_{m}^{\perp}, \mathrm{FO}_{m}^{\perp}$ and $\mathrm{FO}^{\perp}$, of which the security in the QROM was proven by $[11,10]$. However, except the one for $\mathrm{U}_{m}^{X}$ from DS security of underlying DPKE to IND-CCA security of resulting KEM [10], all the reductions are non-tight due to the usage of OW2H lemma. To achieve a DS-secure DPKE, [10] also gave two transformations, TPunc and KC, from an IND-CPA-secure PKE and a OW-CPA-secure DPKE, respectively. But, the security reductions for TPunc and KC are also non-tight due to the utilization of OW2H lemma.

In this section, we will show that if the underlying PKE is assumed to be IND-CPA-secure, tighter reductions for $\mathrm{FO}_{m}^{\not}$ and T can be achieved by using semi-classical oracle technique in [20]. As discussed in Sec. 1.2, we can also use semi-classical oracle technique to obtain tighter security reductions for $\mathrm{FO}^{\not ㇒}$, TPunc, KC, $\mathrm{U}^{\perp}, \mathrm{U}^{\perp}, \mathrm{U}_{m}^{\perp}$ and $\mathrm{U}_{m}^{\perp}$. We present them in Appendix D.

To a public-key encryption scheme $\mathrm{PKE}=(G e n, E n c, D e c)$ with message space $\mathcal{M}$ and randomness space $\mathcal{R}$, hash functions $G: \mathcal{M} \rightarrow \mathcal{R}, H: \mathcal{M} \rightarrow \mathcal{K}$ and a pseudorandom function (PRF) $f$ with key space $\mathcal{K}^{p r f}$, we associate KEM$\mathrm{I}=\mathrm{FO}_{m}^{\perp}[\mathrm{PKE}, G, H, f]$, see Fig. 1.

| $G e n^{\prime}$ | Encaps(pk) | $\operatorname{Decaps}\left(s k^{\prime}, c\right)$ |

Fig. 1: IND-CCA-secure KEM-I $=\mathrm{FO} \frac{1}{m}[\mathrm{PKE}, G, H, f]$

Theorem 1 (PKE IND-CPA $\stackrel{Q R O M}{\Rightarrow}$ KEM-I IND-CCA). If PKE is $\delta$ correct, for any IND-CCA $\mathcal{B}$ against KEM-I, issuing at most $q_{D}$ queries to the
decapsulation oracle Decaps, at most $q_{G}\left(q_{H}\right)$ queries to the random oracle $G$ (H) $\left(\left(q_{G}+q_{H}\right) \geq 1\right)$, there exist an IND-CPA adversary $\mathcal{A}$ against PKE and an adversary $\mathcal{A}^{\prime}$ against the security of PRF with at most $q_{D}$ classical queries such that $\operatorname{Adv}_{\mathrm{KEM}-\mathrm{I}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B}) \leq 2 \sqrt{\left(q_{G}+q_{H}+1\right) \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}(\mathcal{A})+2 \frac{\left(q_{G}+q_{H}+1\right)^{2}}{\mid \mathcal{M |}}}+$ $\operatorname{Adv}_{\operatorname{PRF}}\left(\mathcal{A}^{\prime}\right)+4 q_{G} \sqrt{\delta}$ and the running time of $\mathcal{A}$ is about that of $\mathcal{B}$.
Proof. Here, we follow the proof skeleton of [11, Theorem 2]. Let $\mathcal{B}$ be an adversary against the IND-CCA security of KEM-I, issuing at most $q_{D}$ queries to the decapsulation oracle DECAPS, at most $q_{G}\left(q_{H}\right)$ queries to the random oracle $G(H)$. Denote $\Omega_{G}, \Omega_{H}$ and $\Omega_{H_{q}}$ as the sets of all functions $G: \mathcal{M} \rightarrow \mathcal{R}$, $H: \mathcal{M} \times \mathcal{C} \rightarrow \mathcal{K}$ and $H_{q}: \mathcal{C} \rightarrow \mathcal{K}$, respectively. Consider the games $G_{0}-G_{9}$ in Fig. 2. Although the games $G_{0}-G_{5}$ are essentially the same with the games $G_{0}-G_{5}$ in prior proof of [11, Theorem 2], we still outline them here for readability and completeness. In particular, to apply the semi-classical oracle techniques in [20], we introduce games $G_{6}-G_{9}$, which are different from the proof of [11, Theorem 2], and essential for the improvement of tightness in this paper.

Game $G_{0}$. Since game $G_{0}$ is exactly the IND-CCA game,

$$
\left|\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]-1 / 2\right|=\operatorname{Adv}_{\mathrm{KEM}-\mathrm{I}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B})
$$

Game $G_{1}$. In game $G_{1}$, the Decaps oracle is changed that the pseudorandom function $f$ is replaced by a random function $H_{q}^{\prime}$. Obviously, any distinguisher between $G_{0}$ and $G_{1}$ can be converted into a distinguisher $\mathcal{A}^{\prime}$ between $f$ and $H_{q}^{\prime}$ with at most $q_{D}$ classical queries. Thus,

$$
\left|\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq \operatorname{Adv} \operatorname{PRF}\left(\mathcal{A}^{\prime}\right)
$$

Let $G^{\prime}$ be a random function such that $G^{\prime}(m)$ is sampled according to the uniform distribution over $\mathcal{R}_{\text {good }}(p k, s k, m):=\{r \in \mathcal{R}: \operatorname{Dec}(s k, \operatorname{Enc}(p k, m ; r))=$ $m\}$. Let $\Omega_{G^{\prime}}$ be the set of all functions $G^{\prime}$. Define $\delta(p k, s k, m)=\frac{\left|\mathcal{R} \backslash \mathcal{R}_{\text {good }}(p k, s k, m)\right|}{|\mathcal{R}|}$ as the fraction of bad randomness and $\delta(p k, s k)=\max _{m \in \mathcal{M}} \delta(p k, s k, m)$. With this notation $\delta=\mathbf{E}[\delta(p k, s k)]$, where the expectation is taken over $(p k, s k) \leftarrow G e n$.

Game $G_{2}$. In game $G_{2}$, we replace $G$ by $G^{\prime}$ that uniformly samples from "good" randomness at random, i.e., $G^{\prime} \stackrel{\$}{\leftarrow} \Omega_{G^{\prime}}$. Following the same analysis as in the proof of [11, Theorem 1], we can show that the distinguishing problem between $G_{1}$ and $G_{2}$ is essentially the distinguishing problem between $G$ and $G^{\prime}$, which can be converted into a distinguishing problem between $F_{1}$ and $F_{2}$, where $F_{1}$ is a function such that $F_{1}(m)$ is sampled according to Bernoulli distribution $B_{\delta(p k, s k, m)}$, i.e., $\operatorname{Pr}\left[F_{1}(m)=1\right]=\delta(p k, s k, m)$ and $\operatorname{Pr}\left[F_{1}(m)=\right.$ $0]=1-\delta(p k, s k, m)$, and $F_{2}$ is a constant function that always outputs 0 for any input. Thus, conditioned on a fixed $(p k, s k)$ we obtain by Lemma 2, $\left|\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1:(p k, s k)\right]-\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1:(p k, s k)\right]\right| \leq 2 q_{G} \sqrt{\delta(p k, s k)}$. By averaging over $(p k, s k) \leftarrow G e n$ we finally obtain

$$
\left|\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq 2 q_{G} \mathbf{E}[\sqrt{\delta(p k, s k)}] \leq 2 q_{G} \sqrt{\delta}
$$

\end{aligned}
$$

Fig. 2: Games $G_{0}-G_{9}$ for the proof of Theorem 1

Game $G_{3}$. In $G_{3}, H$ is substituted with $H_{q} \circ g$, where $g(\cdot)=\operatorname{Enc}(p k, \cdot ; G(\cdot))$. Since the $G$ in this game only samples "good" randomness, the function $g$ is injective. Thus, $H_{q} \circ g$ is a perfect random function. Therefore, $G_{2}$ and $G_{3}$ are statistically indistinguishable and we have $\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Pr}\left[G_{3}^{\mathcal{B}} \Rightarrow 1\right]$.

Game $G_{4}$. In game $G_{4}$, the Decaps oracle is changed that it makes no use of the secret key $s k^{\prime}$ any more. When $\mathcal{B}$ queries the Decaps oracle on $c\left(c \neq c^{*}\right)$, $K:=H_{q}(c)$ is returned as the response. Let $m^{\prime}:=\operatorname{Dec}(s k, c)$ and consider the following two cases.

Case 1: $\operatorname{Enc}\left(p k, m^{\prime} ; G\left(m^{\prime}\right)\right)=c$. In this case, $H\left(m^{\prime}\right)=H_{q}(c)$ and both DECAPS oracles in $G_{3}$ and $G_{4}$ return the same value.
Case 2: $\operatorname{Enc}\left(p k, m^{\prime} ; G\left(m^{\prime}\right)\right) \neq c$. In this case, $H_{q}^{\prime}(c)$ and $H_{q}(c)$ are respectively returned in $G_{3}$ and $G_{4}$. In $G_{3}, H_{q}^{\prime}(c)$ is uniformly random and independent of the oracles $G$ and $H$ in $\mathcal{B}$ 's view. In $G_{4}$, queries to $H$ can only reveal $H_{q}(\hat{c})$, where $\hat{c}$ satisfies $g(\hat{m})=\hat{c}$ for some $\hat{m}$. If there exists a $\hat{m}$ such that $\operatorname{Enc}(p k, \hat{m} ; G(\hat{m}))=c, \hat{m}=m^{\prime}$ since $G$ in this game only samples from "good" randomness. Thus, $\operatorname{Enc}\left(p k, m^{\prime} ; G\left(m^{\prime}\right)\right)=c$ will contradict the condition $\operatorname{Enc}\left(p k, m^{\prime} ; G\left(m^{\prime}\right)\right) \neq c$. Consequently, $H_{q}(c)$ is also a fresh random key just like $H_{q}^{\prime}(c)$ in $\mathcal{B}$ 's view. Hence, in this case, the output distributions of the DEcaps oracles in $G_{3}$ and $G_{4}$ are identical in $\mathcal{B}$ 's view.

As a result, the output distributions of $G_{3}$ and $G_{4}$ are statistically indistinguishable and we have $\operatorname{Pr}\left[G_{3}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Pr}\left[G_{4}^{\mathcal{B}} \Rightarrow 1\right]$.

Game $G_{5}$. In game $G_{5}$, we replace $G^{\prime}$ by $G$, that is, $G$ in this game is reset to be an ideal random oracle. Then, following the same analysis as in bounding the difference between $G_{1}$ and $G_{2}$, we can have

$$
\left|\operatorname{Pr}\left[G_{4}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{5}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq 2 q_{G} \sqrt{\delta}
$$

Let $\ddot{G}(\ddot{H})$ be the function such that $\ddot{G}\left(m^{*}\right)\left(\ddot{H}\left(m^{*}\right)\right)$ is picked uniformly at random from $\mathcal{R}(\mathcal{K})$, and $\ddot{G}=G(\ddot{H}=H)$ everywhere else. In the proof of [11, Theorem 2], $G$ and $H$ in game $G_{5}$ are directly reprogrammed to $\ddot{G}$ and $\ddot{H}$, respectively, and then the OW2H lemma is used to argue the indistinguishability.

Here, in order to use the semi-classical OW2H lemma, we reprogram $G$ and $H$ in game $G_{5}$ with an additional semi-classical oracle. Thereby, we need to consider the simulation of such a semi-classical oracle, which is unnecessary in the proof of [11, Theorem 2]. As discussed in Sec. 1.2, this semi-classical oracle can be simulated under the IND-CPA security assumption. Thus, we present following gamehops from $G_{6}$ to $G_{9}$.

Game $G_{6}$. In game $G_{6}$, replace $G$ and $H$ by $\ddot{G} \backslash m^{*}$ and $\ddot{H} \backslash m^{*}$ respectively. For $\mathcal{B}$ 's query to $\ddot{G} \backslash m^{*}\left(\ddot{H} \backslash m^{*}\right), \ddot{G} \backslash m^{*}\left(\ddot{H} \backslash m^{*}\right)$ will first query a semi-classical oracle $\mathcal{O}_{m^{*}}^{S C}$, i.e., perform a semi-classical measurement, and then query $\ddot{G}(\ddot{H})$. Let Find be the event that $\mathcal{O}_{m^{*}}^{S C}$ ever outputs 1 during semi-classical measurements of $\mathcal{B}^{\prime} s$ queries to $\ddot{G} \backslash m^{*}$ and $\ddot{H} \backslash m^{*}$. Note that if the event $\neg$ Find that $\mathcal{O}_{m^{*}}^{S C}$ always outputs 0 happens, $\mathcal{B}$ never learns the values of $G\left(m^{*}\right)$ and $H\left(m^{*}\right)$ and bit $b$ is independent of $\mathcal{B}$ 's view. That is, $\operatorname{Pr}\left[G_{6}^{\mathcal{B}} \Rightarrow 1: \neg\right.$ Find $]=1 / 2$. Hence,

$$
\operatorname{Pr}\left[G_{6}^{\mathcal{B}} \Rightarrow 1 \wedge \neg \text { Find }: G_{6}\right]=1 / 2 \operatorname{Pr}\left[\neg \text { Find }: G_{6}\right]=1 / 2\left(1-\operatorname{Pr}\left[\text { Find }: G_{6}\right]\right)
$$

$\operatorname{Let}(G \times H)(\cdot)=(G(\cdot), H(\cdot)),(\ddot{G} \times \ddot{H})(\cdot)=(\ddot{G}(\cdot), \ddot{H}(\cdot))$, and $(\ddot{G} \times \ddot{H}) \backslash m^{*}(\cdot)=$ $\left(\ddot{G} \backslash m^{*}(\cdot), \ddot{H} \backslash m^{*}(\cdot)\right)$. If one wants to make queries to $G$ (or $H$ ) by accessing to $G \times H$, he just needs to prepare a uniform superposition of all states in the output register responding to $H$ (or $G$ ). The number of total queries to $G \times H$ is at most $q_{G}+q_{H}$.

$$
\begin{array}{lll}
\frac{A^{G \times H}\left(p k, c^{*}, H\left(m^{*}\right), H_{q}\right)}{} & & \text { DECAPS }\left(c \neq c^{*}\right) \\
\hline 1: & k_{0}^{*}=H\left(m^{*}\right) ; k_{1}^{*} \stackrel{\&}{\leftarrow} \mathcal{K} ; b \stackrel{\&}{\leftarrow}\{0,1\} & 1: \\
2: & b^{\prime} \leftarrow \mathcal{B}^{G, H, \text { Decaps }}\left(p k, c^{*}, k_{b}^{*}\right) & \\
3: & \text { return } b^{\prime}=? b &
\end{array}
$$

Fig. 3: $A^{G \times H}$ for the proof of Theorem 1.

Let $A^{G \times H}$ be an oracle algorithm on input $\left(p k, c^{*}, H\left(m^{*}\right), H_{q}\right)^{8}$ in Fig. 3. Sample $p k, m^{*}, G, H_{q}, H$ and $c^{*}$ in the same way as $G_{5}$ and $G_{6}$, i.e., $(p k, s k) \leftarrow G e n, m^{*} \stackrel{\&}{\leftarrow} \mathcal{M}, G \stackrel{\&}{\leftarrow} \Omega_{G}, H_{q} \stackrel{\&}{\leftarrow} \Omega_{H_{q}}, H:=H_{q} \circ g$ and $c^{*}=$ $\operatorname{Enc}\left(p k, m^{*} ; G\left(m^{*}\right)\right)$. Then, $A^{G \times H}\left(p k, c^{*}, H\left(m^{*}\right), H_{q}\right)$ perfectly simulates $G_{5}$, and $A^{(\ddot{G} \times \ddot{H}) \backslash m^{*}}\left(p k, c^{*}, H\left(m^{*}\right), H_{q}\right)$ perfectly simulates $G_{6}$. Applying Lemma 3 with $X=\mathcal{M}, Y=(\mathcal{R}, \mathcal{K}), S=\left\{m^{*}\right\}, \mathcal{O}_{1}=G \times H, \mathcal{O}_{2}=\ddot{G} \times \ddot{H}$ and $z=\left(p k, c^{*}, H\left(m^{*}\right), H_{q}\right)$ and $A$, we can have

$$
\mid \operatorname{Pr}\left[G_{5}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{6}^{\mathcal{B}} \Rightarrow 1 \wedge \neg \text { Find }: G_{6}\right] \mid \leq \sqrt{\left(q_{G}+q_{H}+1\right) \operatorname{Pr}\left[\text { Find }: G_{6}\right]} .
$$

Game $G_{7}$. In game $G_{7}$, replace $r^{*}:=G\left(m^{*}\right)$ and $k_{0}^{*}:=H\left(m^{*}\right)$ by $r^{*} \stackrel{\$}{\leftarrow} \mathcal{R}$ and $k_{0}^{*} \stackrel{\$}{\leftarrow} \mathcal{K}$. We do not care about $\mathcal{B}$ 's output, but only whether the event Find happens. Note that in $G_{6}$ and $G_{7}$, there is no information of $\left(G\left(m^{*}\right), H\left(m^{*}\right)\right)$ in the oracle $\ddot{G} \times \ddot{H}$. Thus, apparently, $\operatorname{Pr}\left[\right.$ Find $\left.: G_{6}\right]=\operatorname{Pr}\left[\right.$ Find $\left.\left.: G_{7}\right]\right]$.

Game $G_{8}$. In game $G_{8}$, replace $\ddot{G}$ and $\ddot{H}$ by $G$ and $H$. Since $G\left(m^{*}\right)$ and $H\left(m^{*}\right)$ are never used in simulating $\mathcal{B}$ 's view, such a replacement causes no difference from $\mathcal{B}$ 's view and we have $\operatorname{Pr}\left[\right.$ Find $\left.: G_{7}\right]=\operatorname{Pr}\left[\right.$ Find $\left.: G_{8}\right]$.

Game $G_{9}$. In game $G_{9}$, replace $m^{*}$ by $m^{\prime *}$. Note that the information of $m^{*}$ in this game only exists in the oracles $G \backslash m^{*}$ and $H \backslash m^{*}$. By Lemma 4,

$$
\operatorname{Pr}\left[\text { Find }: G_{9}\right] \leq 4\left(q_{G}+q_{H} /|\mathcal{M}|\right) \text {. }
$$

[^2]| $\mathcal{A}\left(1^{\lambda}, p k\right)$ |  |
| :---: | :---: |
| 1: $\quad m^{*}, m^{\prime *} \stackrel{\$}{\leftarrow} \mathcal{M} ; m_{0}=m^{*} ; m_{1}=m^{\prime *} ; k^{*} \stackrel{\$}{\leftarrow} \mathcal{K}$ | $H(m)$ |
| $2: \quad b^{\prime \prime} \stackrel{\$}{\leftarrow}\{0,1\} ; r^{*} \stackrel{\&}{\leftarrow} \mathcal{R} ; c^{*}=\operatorname{Enc}\left(p k, m_{b^{\prime \prime}} ; r^{*}\right)$ <br> 3: Pick a $2 q_{G}\left(2 q_{H}\right)$-wise function $G\left(H_{q}\right)$ | $\begin{array}{ll} 1: & g(\cdot):=\operatorname{Enc}\left(p k, \cdot ; G \backslash m_{0}(\cdot)\right) \\ 2: & \text { return } H_{q} \circ g(m) \end{array}$ |
| 4: $\quad b^{\prime} \leftarrow \mathcal{B}^{G \backslash m_{0}, H \backslash m_{0}, \text { Decaps }}\left(p k, c^{*}, k^{*}\right)$ | DECAPS $\left(c \neq c^{*}\right)$ |
| 5 : return Find | 1: return $K:=H_{q}(c)$ |

Fig. 4: Adversary $\mathcal{A}$ for the proof of Theorem 1

Next, we show that any adversary distinguishing $G_{8}$ from $G_{9}$ can be converted into an adversary against the IND-CPA security of underlying PKE. Construct an adversary $\mathcal{A}$ on input $\left(1^{\lambda}, p k\right)$ as in Fig. 4. Then, according to Lemma 1 , if $b^{\prime \prime}=0, \mathcal{A}$ perfectly simulates $G_{8}$ and $\operatorname{Pr}\left[\right.$ Find $\left.: G_{8}\right]=\operatorname{Pr}\left[1 \leftarrow \mathcal{A}: b^{\prime \prime}=0\right]$. If $b^{\prime \prime}=1, \mathcal{A}$ perfectly simulates $G_{9}$ and $\operatorname{Pr}\left[\right.$ Find $\left.: G_{9}\right]=\operatorname{Pr}\left[1 \leftarrow \mathcal{A}: b^{\prime \prime}=1\right]$. Since $\operatorname{Adv}_{\operatorname{PKE}}^{\operatorname{IND}-\operatorname{CPA}}(\mathcal{A})=1 / 2\left|\operatorname{Pr}\left[1 \leftarrow \mathcal{A}: b^{\prime \prime}=0\right]-\operatorname{Pr}\left[1 \leftarrow \mathcal{A}: b^{\prime \prime}=1\right]\right|$,

$$
\mid \operatorname{Pr}\left[\text { Find }: G_{8}\right]-\operatorname{Pr}\left[\text { Find }: G_{9}\right] \mid=2 \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}(\mathcal{A})
$$

Finally, combing this with the bounds derived above, we have $\operatorname{Adv}_{\text {KEM-I }}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B})$

$$
\begin{aligned}
& \leq \operatorname{Adv}_{\mathrm{PRF}}\left(\mathcal{A}^{\prime}\right)+4 q_{G} \sqrt{\delta}+1 / 2 \operatorname{Pr}\left[\text { Find }: G_{6}\right]+\sqrt{\left(q_{G}+q_{H}+1\right) \operatorname{Pr}\left[\text { Find }: G_{6}\right]} \\
& \leq \operatorname{Adv}_{\operatorname{PRF}}\left(\mathcal{A}^{\prime}\right)+4 q_{G} \sqrt{\delta}+\sqrt{2\left(q_{G}+q_{H}+1\right) \operatorname{Pr}\left[\text { Find }: G_{6}\right]} \\
& \leq \operatorname{Adv}_{\operatorname{PRF}}\left(\mathcal{A}^{\prime}\right)+4 q_{G} \sqrt{\delta}+2 \sqrt{\left(q_{G}+q_{H}+1\right) \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}(\mathcal{A})+2 \frac{\left(q_{G}+q_{H}+1\right)^{2}}{\mid \mathcal{M |}}}
\end{aligned}
$$

The transformation T $[25,4]$ turns a probabilistic PKE into a determined one by derandomization and re-encryption [25,26]. To a PKE=(Gen, Enc, Dec) with message space $\mathcal{M}$ and randomness space $R$, and a random oracle $G: \mathcal{M} \rightarrow \mathcal{R}$, we associate $\mathrm{PKE}^{\prime}=\left(G e n^{\prime}, E n c^{\prime}, D e c^{\prime}\right)=\mathrm{T}[\mathrm{PKE}, G]$, see Fig. 5. As discussed in Sec. 1.2, for T, using semi-classical OW2H lemma with bound (3), we can improve the reduction in [11] and reduce the quadratic security loss to a linear one. The complete proof of Theorem 2 is presented in Appendix B.

| $G e n^{\prime}$ | $E n c^{\prime}(p k, m)$ | $D e c^{\prime}(s k, c)$ |
| :---: | :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n$ | 1: c $\quad$ = $\operatorname{nc}(p k, m ; G(m))$ | 1: $\quad m^{\prime}:=\operatorname{Dec}(s k, c)$ |
| 2: return $(p k, s k)$ | 2: return $c$ | ```2: if \(\operatorname{Enc}\left(p k, m^{\prime} ; G\left(m^{\prime}\right)\right)=c\) 3: return \(m^{\prime}\) 4: else return \(\perp\)``` |

Fig. 5: OW-qPCA-secure $\mathrm{PKE}^{\prime}=\mathrm{T}[\mathrm{PKE}, G]$

Theorem 2 (PKE IND-CPA $\stackrel{Q R O M}{\Rightarrow}{ }^{\prime} \mathbf{P K E}^{\prime} \mathbf{O W}$-qPCA). If PKE is $\delta$-correct, for any $O W-q P C A \mathcal{B}$ against $\mathrm{PKE}^{\prime}$, issuing at most $q_{G}$ quantum queries to the random oracle $G$ and at most $q_{P}$ quantum queries to the plaintext checking oracle PCO, there exists an IND-CPA adversary $\mathcal{A}$ against PKE such that $\operatorname{Adv}_{\mathrm{PKE}} \mathrm{OWCA}^{\mathrm{OW}}(\mathcal{B}) \leq 4 q_{G} \sqrt{\delta}+2\left(q_{G}+2\right) \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}(\mathcal{A})+4 \frac{\left(q_{G}+2\right)^{2}}{|\mathcal{M}|}$ and the running time of $\mathcal{A}$ is about that of $\mathcal{B}$.

## A Cryptographic Primitives

Definition 1 (Public-key encryption). A public-key encryption scheme PKE consists of three algorithms. The key generation algorithm, Gen, is a probabilistic algorithm which on input $1^{\lambda}$ outputs a public/secret key-pair ( $p k, s k$ ). The encryption algorithm Enc, on input $p k$ and a message $m \in \mathcal{M}$, outputs a ciphertext $c \leftarrow \operatorname{Enc}(p k, m)$. If necessary, we make the used randomness of encryption explicit by writing $c:=\operatorname{Enc}(p k, m ; r)$, where $r \stackrel{\$}{\leftarrow} \mathcal{R}(\mathcal{R}$ is the randomness $s$ pace). The decryption algorithm Dec, is a deterministic algorithm which on input sk and a ciphertext $c$ outputs a message $m:=\operatorname{Dec}(s k, c)$ or a rejection symbol $\perp \notin \mathcal{M}$. A PKE is determined if Enc is deterministic. We denote DPKE to stand for a determined PKE.

Definition 2 (Correctness [4]). A public-key encryption scheme PKE is $\delta$ correct if $E\left[\max _{m \in \mathcal{M}} \operatorname{Pr}[\operatorname{Dec}(s k, c) \neq m: c \leftarrow \operatorname{Enc}(p k, m)]\right] \leq \delta$, where the expectation is taken over $(p k, s k) \leftarrow G e n . ~ A ~ P K E ~ i s ~ p e r f e c t l y ~ c o r r e c t ~ i f ~ \delta=0 . ~$

Definition 3 (DS-secure DPKE [10]). Let $D_{\mathcal{M}}$ denote an efficiently sampleable distribution on a set $\mathcal{M}$. A DPKE scheme (Gen,Enc,Dec) with plaintext and ciphertext spaces $\mathcal{M}$ and $\mathcal{C}$ is $D_{\mathcal{M}}$-disjoint simulatable if there exists a $P P T$ algorithm $S$ that satisfies the following,
(1) Statistical disjointness:

$$
\operatorname{DISJ}_{\mathrm{PKE}, S}:=\max _{(p k, s k) \in G e n\left(1^{\lambda} ; \mathcal{R}_{g e n}\right)} \operatorname{Pr}[c \in \operatorname{Enc}(p k, \mathcal{M}): c \leftarrow S(p k)]
$$

is negligible, where $\mathcal{R}_{\text {gen }}$ denotes a randomness space for Gen.
(2) Ciphertext indistinguishability: For any PPT adversary $\mathcal{A}$,

$$
\operatorname{Adv}_{\mathrm{PKE}, D_{\mathcal{M}}, S}^{\mathrm{DS}-\mathrm{A})}:=\left|\begin{array}{c}
\operatorname{Pr}\left[\mathcal{A}\left(p k, c^{*}\right) \rightarrow 1: \begin{array}{c}
(p k, s k) \leftarrow G e n ; m^{*} \leftarrow D_{\mathcal{M}} ; \\
\left.c^{*}=\operatorname{Enc}\left(p k, m^{*}\right)\right]
\end{array}\right] \\
-\operatorname{Pr}\left[\mathcal{A}\left(p k, c^{*}\right) \rightarrow 1:(p k, s k) \leftarrow G e n ; c^{*} \leftarrow S(p k)\right]
\end{array}\right|
$$

is negligible.

| Game OW-ATK | $\mathrm{PCO}(m, c)$ |  | $\mathrm{VAL}(c)$ |  |
| :---: | :---: | :---: | :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n$ | 1: | if $m \notin \mathcal{M}$ |  | $m:=\operatorname{Dec}(s k, c)$ |
| 2: $\quad m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}$ | 2 : | return $\perp$ |  | if $m \in \mathcal{M}$ |
| 3: $\quad c^{*} \leftarrow \operatorname{Enc}\left(p k, m^{*}\right)$ | 3 : | else return | 3 : | return 1 |
| $4: \quad m^{\prime} \leftarrow \mathcal{A}^{O_{\mathrm{ATK}}}\left(p k, c^{*}\right)$ | 4: | $\operatorname{Dec}(s k, c)=? m$ |  | else return 0 |
| 5 : return $m^{\prime}=$ ? $m^{*}$ |  |  |  |  |

Fig. 6: Games OW-ATK (ATK $\in\{\mathrm{CPA}, \mathrm{VA}, \mathrm{qPCA}, \mathrm{qPVCA}\})$ for PKE, where $O_{\text {AtK }}$ is defined in Definition 4. In games qPCA and qPVCA, the adversary $\mathcal{A}$ can query the PCO oracle with quantum state.

| Game IND-CPA for PKE | Game IND-CCA for KEM | DECAPS $(s k, c)$ |
| :---: | :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n$ | 1: $\quad(p k, s k) \leftarrow G e n$ | $1: \quad$ if $c=c^{*}$ |
| 2: $b \leftarrow\{0,1\}$ | $2: \quad b \stackrel{\$}{\leftarrow}\{0,1\}$ | 2: return $\perp$ |
| $3: \quad\left(m_{0}, m_{1}\right) \leftarrow \mathcal{A}(p k)$ | 3: $\left(K_{0}^{*}, c^{*}\right) \leftarrow \operatorname{Encaps}(p k)$ | 3 : else return |
| 4: $\quad c^{*} \leftarrow \operatorname{Enc}\left(p k, m_{b}\right)$ | $4: \quad K_{1}^{*} \stackrel{\Phi}{\leftarrow} \mathcal{K}$ | 4: $\quad K:=\operatorname{Decaps}(s k, c)$ |
| $5: \quad b^{\prime} \leftarrow \mathcal{A}\left(p k, c^{*}\right)$ <br> 6: return $b^{\prime}=? b$ | $5: \quad b^{\prime} \leftarrow \mathcal{A}^{\text {Decaps }}\left(p k, c^{*}, K_{b}^{*}\right)$ |  |
|  | 6 : return $b^{\prime}=? b$ |  |

Fig. 7: IND-CPA game for PKE and IND-CCA game for KEM.

Definition 4 (OW-ATK-secure PKE). Let PKE = (Gen, Enc, Dec) be a public-key encryption scheme with message space $\mathcal{M}$. For ATK $\in\{$ CPA, VA, qPCA, qPVCA\} [11], we define $O W$-ATK games as in Fig. 6, where

$$
O_{A T K}:=\left\{\begin{array}{cl}
\perp & \mathrm{ATK}=\mathrm{CPA} \\
\operatorname{VAL}(\cdot) & \mathrm{ATK}=\mathrm{VA} \\
\operatorname{PCO}(\cdot, \cdot) & \mathrm{ATK}=\mathrm{qPCA} \\
\operatorname{PCO}(\cdot, \cdot), \operatorname{VAL}(\cdot) & \mathrm{ATK}=\mathrm{qPVCA}
\end{array}\right.
$$

Define the OW-ATK advantage function of an adversary $\mathcal{A}$ against PKE as $\operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{OW}-\operatorname{ATK}}(\mathcal{A}):=\operatorname{Pr}\left[\mathrm{OW}-\mathrm{ATK}_{\mathrm{PKE}}^{\mathcal{A}}=1\right]$.

Definition 5 (IND-CPA-secure PKE). Define IND - CPA game of PKE as in Fig. 7 and the IND - CPA advantage function of an adversary $\mathcal{A}$ against $P K E$ as $\operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}(\mathcal{A}):=\left|\operatorname{Pr}\left[\operatorname{IND}-\mathrm{CPA}_{\mathrm{PKE}}^{\mathcal{A}}=1\right]-1 / 2\right|$.
Definition 6 (Key encapsulation). A key encapsulation mechanism KEM consists of three algorithms. The key generation algorithm Gen outputs a key pair $(p k, s k)$. The encapsulation algorithm Encaps, on input pk, outputs a tuple $(K, c)$, where $K \in \mathcal{K}$ and $c$ is said to be an encapsulation of the key $K$. The deterministic decapsulation algorithm Decaps, on input sk and an encapsulation $c$, outputs either a key $K:=\operatorname{Decaps}(s k, c) \in \mathcal{K}$ or a rejection symbol $\perp \notin \mathcal{K}$.

Definition 7 (IND-CCA-secure KEM). We define the IND - CCA game as in Fig. 7 and the IND - CCA advantage function of an adversary $\mathcal{A}$ against $\operatorname{KEM}$ as $\operatorname{Adv}_{\mathrm{KEM}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{A}):=\left|\operatorname{Pr}\left[\operatorname{IND}-\mathrm{CCA}_{\mathrm{KEM}}^{\mathcal{A}}=1\right]-1 / 2\right|$.

## B Proof of Theorem 2

Proof. Let $\mathcal{B}$ be an adversary against the OW-qPCA security of $\mathrm{PKE}^{\prime}$, issuing at most $q_{P C}$ queries to the oracle PCO, at most $q_{G}$ queries to the random oracle $G$. Denote $\Omega_{G}$ as the sets of all functions $G: \mathcal{M} \rightarrow \mathcal{R}$. Let $G^{\prime}$ be a random function such that $G^{\prime}(m)$ is sampled according to the uniform distribution in $\mathcal{R}_{\text {good }}(p k, s k, m)$, where $\mathcal{R}_{\text {good }}(p k, s k, m):=\{r \in \mathcal{R}: \operatorname{Dec}(s k, \operatorname{Enc}(p k, m ; r))=$ $m\}$. Let $\Omega_{G^{\prime}}$ be the set of all functions $G^{\prime}$. Let $\delta(p k, s k, m)=\frac{\left|\mathcal{R}_{\mathrm{bad}}(p k, s k, m)\right|}{|\mathcal{R}|}$ as
the fraction of bad randomness, where $\mathcal{R}_{\text {bad }}(p k, s k, m)=\mathcal{R} \backslash \mathcal{R}_{\text {good }}(p k, s k, m)$. $\delta(p k, s k)=\max _{m \in \mathcal{M}} \delta(p k, s k, m) . \delta=\mathbf{E}[\delta(p k, s k)]$, where the expectation is taken over $(p k, s k) \leftarrow G e n$. Consider the games in Fig. 8 .

Game $G_{0}$. Since game $G_{0}$ is exactly the OW-qPCA game,

$$
\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Adv}_{\mathrm{PKE}^{\prime}}^{O W-q P C A}(\mathcal{B}) .
$$

```
GAMES \(G_{0}-G_{6}\)
GAMES \(G_{0}-G_{6}\)
\((p k, s k) \leftarrow G e n ; G \stackrel{\$}{\leftarrow} \Omega_{G}\)
\(G^{\prime} \stackrel{\&}{\leftarrow} \Omega_{G^{\prime}} ; G:=G^{\prime} \quad / / G_{1}-G_{2}\)
\(m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}\)
\(r^{*}:=G\left(m^{*}\right)\)
\(r^{*} \stackrel{\$}{\leftarrow} \mathcal{R} \quad / / G_{6}\)
\(c^{*}:=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right) / / G_{0}-G_{6}\)
\(g(\cdot):=\operatorname{Enc}(p k, \cdot ; G(\cdot)) / / G_{0}-G_{4}\)
\(m^{\prime} \leftarrow \mathcal{B}^{G, \mathrm{PCO}}\left(p k, c^{*}\right) / / G_{0}-G_{4}\)
\(\ddot{G}=G ; \ddot{G}\left(m^{*}\right) \stackrel{\$}{\leftarrow} / / G_{5}-G_{6}\)
    \(g(\cdot):=\operatorname{Enc}\left(p k, \cdot ; \ddot{G} \backslash m^{*}(\cdot)\right) / / G_{5}-G_{6}\)
    \(m^{\prime} \leftarrow \mathcal{B}^{\ddot{G} \backslash m^{*}, \mathrm{PCO}}\left(p k, c^{*}\right) / / G_{5}-G_{6}\)
    Query \(G\) with input \(m^{\prime} / / G_{4}-G_{6}\)
    return \(m^{\prime}=? m^{*}\)
```

Fig. 8: Games $G_{0}-G_{6}$ for the proof of Theorem 2

Game $G_{1}$. In game $G_{1}$, we replace $G$ by $G^{\prime}$ that uniformly samples from "good" randomness at random, i.e., $G^{\prime} \stackrel{\$}{\leftarrow} \Omega_{G^{\prime}}$. Following the same analysis as in the proof of Theorem 1, we can have

$$
\left|\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq 2 q_{G} \sqrt{\delta}
$$

Game $G_{2}$. In game $G_{2}$, the PCO oracle is changed that it makes no use of the secret key $s k$ any more. Particularly, when $\mathcal{B}$ queries $P C O$ oracle, $\operatorname{Enc}(p k, m ; G(m))=$ $? c$ is returned instead of $\operatorname{Dec}^{\prime}(s k, c)=? m$. It is easy to verify that $D e c^{\prime}(s k, c)=$ $? m$ is equal to $\operatorname{Dec}(s k, c)=? m \wedge \operatorname{Enc}(p k, m ; G(m))=? c$. Thus, the outputs of the $P C O$ oracles in $G_{1}$ and $G_{2}$ merely differs for the case of $\operatorname{Dec}(s k, c) \neq m$ and $\operatorname{Enc}(p k, m ; G(m))=c$. But, such a case does not exist since $G$ in this game only samples from "good" randomness. That is, the $P C O$ oracle in $G_{2}$ always has the identical output with the one in $G_{1}$. Therefore, we have

$$
\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]
$$

Game $G_{3}$. In game $G_{3}$, we switch the $G$ that only samples from "good" randomness back to an ideal random oracle $G$. Then, similar to the case of $G_{0}$ and $G_{1}$, the distinguishing problem between $G_{2}$ and $G_{3}$ can also be converted to the distinguishing problem between $G$ and $G^{\prime}$. Using the same analysis method in bounding the difference between $G_{0}$ and $G_{1}$, we can have

$$
\left|\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{3}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq 2 q_{G} \sqrt{\delta}
$$

Game $G_{4}$. In game $G_{4}$, an additional query to $G$ with classical state $\left|m^{\prime}\right\rangle|0\rangle$ is performed after $\mathcal{B}$ returns $m^{\prime}$. Obviously, $G_{4}$ has the same output as $G_{3}$ and we have

$$
\operatorname{Pr}\left[G_{3}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Pr}\left[G_{4}^{\mathcal{B}} \Rightarrow 1\right]
$$

Let $\ddot{G}$ be the function that $\ddot{G}\left(m^{*}\right)=\ddot{r}^{*}$, and $\ddot{G}=G$ everywhere else, where $\ddot{r}^{*}$ is picked uniformly at random from $\mathcal{R}$.

Game $G_{5}$. In game $G_{5}$, we replace $G$ by a semi-classical oracle $\ddot{G} \backslash m^{*}$. For a query input, $\ddot{G} \backslash m^{*}$ will first query $\mathcal{O}_{m^{*}}^{S C}$, i.e., perform a semi-classical measurement, and then query $\ddot{G}$. Let Find be the event that $\mathcal{O}_{m^{*}}^{S C}$ ever outputs 1 during semiclassical measurements of the queries to $\ddot{G} \backslash m^{*}$. We note that

$$
\operatorname{Pr}\left[G_{5}^{\mathcal{B}} \Rightarrow 1 \wedge \neg \text { Find }: G_{5}\right]=0
$$

since $G_{5}^{\mathcal{B}} \Rightarrow 1$ implies that $m^{\prime}=m^{*}$ in $G_{5}$, and $\ddot{G}$ is classically queried at $m^{\prime}$ in $G_{5}{ }^{9}$. Applying Lemma 3 with $X=\mathcal{M}, Y=\mathcal{R}, S=\left\{m^{*}\right\}, \mathcal{O}_{1}=G, \mathcal{O}_{2}=\ddot{G}$ and $z=\left(p k, c^{*}\right)$, we can have

$$
\left|\sqrt{\operatorname{Pr}\left[G_{4}^{\mathcal{B}} \Rightarrow 1\right]}-\sqrt{\operatorname{Pr}\left[G_{5}^{\mathcal{B}} \Rightarrow 1 \wedge \neg \text { Find }: G_{5}\right]}\right| \leq \sqrt{\left(q_{G}+2\right) \operatorname{Pr}\left[\text { Find }: G_{5}\right]} .
$$

Game $G_{6}$. In game $G_{6}$, we replace $r^{*}:=G\left(m^{*}\right)$ by $r^{*} \stackrel{\$ \mathcal{R}}{\leftarrow}$. Since $G\left(m^{*}\right)$ is only used once and independent of the oracles $\ddot{G}$ and $P C O$,

$$
\operatorname{Pr}\left[\text { Find }: G_{5}\right]=\operatorname{Pr}\left[\text { Find }: G_{6}\right]
$$

Note that $G\left(m^{*}\right)$ is never used in $G_{6}$, we can just replace $G \stackrel{\$}{\leftarrow} \Omega_{G} ; \ddot{G}=$ $G ; \ddot{G}\left(m^{*}\right) \stackrel{\$}{\leftarrow} \mathcal{R}$ by $\ddot{G} \stackrel{\$}{\leftarrow} \Omega_{G}$. For brevity and readability, we will substitute the notation $\ddot{G}$ with notation $G$. Then, game $G_{6}$ can be rewritten as in Fig. 9 .

Game $G_{7}$. In game $G_{7}$, we replace $c^{*}:=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right)$ by $c^{*}:=\operatorname{Enc}\left(p k, m_{1}^{*} ; r^{*}\right)$, where $m_{1}^{*} \stackrel{\$}{\leftarrow} \mathcal{M}$. Note that the information of $m^{*}$ in this game only exists in the oracle $G \backslash m^{*}$, by Lemma 4 we have

$$
\operatorname{Pr}\left[\text { Find }: G_{7}\right] \leq 4 \frac{q_{G}+1}{|\mathcal{M}|}
$$

[^3]Next, we show that any adversary distinguishing $G_{6}$ from $G_{7}$ can be converted into an adversary against the IND-CPA security of underlying PKE scheme. Construct an adversary $\mathcal{A}$ on input $\left(1^{\lambda}, p k\right)$ as in Fig. 10, where Find is 1 iff the event Find that $\mathcal{O}_{m_{0}}^{S C}$ ever outputs 1 during semi-classical measurements of the queries to $G \backslash m_{0}$ happens. Then, according to Lemma 1 , if $b^{\prime \prime}=0, \mathcal{A}$ perfectly simulates $G_{6}$ and $\operatorname{Pr}\left[\right.$ Find $\left.: G_{6}\right]=\operatorname{Pr}\left[1 \leftarrow \mathcal{A}: b^{\prime \prime}=0\right]$. If $b^{\prime \prime}=1$, $\mathcal{A}$ perfectly simulates $G_{7}$ and $\operatorname{Pr}\left[\right.$ Find $\left.: G_{7}\right]=\operatorname{Pr}\left[1 \leftarrow \mathcal{A}: b^{\prime \prime}=1\right]$. Since $\operatorname{Adv}_{\operatorname{PKE}}^{\mathrm{IND}-\mathrm{CPA}}(\mathcal{A})=1 / 2\left|\operatorname{Pr}\left[1 \leftarrow \mathcal{A}: b^{\prime \prime}=0\right]-\operatorname{Pr}\left[1 \leftarrow \mathcal{A}: b^{\prime \prime}=1\right]\right|$,

$$
\mid \operatorname{Pr}\left[\text { Find }: G_{6}\right]-\operatorname{Pr}\left[\text { Find }: G_{7}\right] \mid=2 \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\operatorname{CPA}}(\mathcal{A})
$$

| GAMES $G_{6}$ | GAMES $G_{7}$ |
| :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n ; G \stackrel{\$}{\leftarrow} \Omega_{G}$ | 1: $\quad(p k, s k) \leftarrow G e n ; G \stackrel{\$}{\leftarrow} \Omega_{G}$ |
| 2: $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M} ; r^{*} \stackrel{\$}{\leftarrow} \mathcal{R}$ | 2: $\quad m^{*}, m_{1}^{*} \stackrel{\$}{\leftarrow} \mathcal{M} ; r^{*} \stackrel{\$}{\leftarrow} \mathcal{R}$ |
| $3: \quad c^{*}:=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right)$ | $3: \quad c^{*}:=\operatorname{Enc}\left(p k, m_{1}^{*} ; r^{*}\right)$ |
| 4: $\quad g(\cdot):=\operatorname{Enc}\left(p k, \cdot ; G \backslash m^{*}(\cdot)\right)$ | 4: $\quad g(\cdot):=\operatorname{Enc}\left(p k, \cdot ; G \backslash m^{*}(\cdot)\right)$ |
| $5: \quad m^{\prime} \leftarrow \mathcal{B}^{G \backslash m^{*}, \mathrm{PCO}}\left(p k, c^{*}\right)$ | $5: \quad m^{\prime} \leftarrow \mathcal{B}^{G \backslash m^{*}, \mathrm{PCO}}\left(p k, c^{*}\right)$ |
| 6: Query $G$ with input $m^{\prime}$ | 6: Query $G$ with input $m^{\prime}$ |
| 7: return $m^{\prime}=$ ? $m^{*}$ | 7 : return $m^{\prime}=? m^{*}$ |
| $\underline{\operatorname{PCO}(m, c) \quad / / G_{6}-G_{7}}$ |  |
| 1: if $m \notin \mathcal{M}$ return $\perp$ |  |
| 2: else return |  |
| $3: \quad g(m)=$ ? $c$ |  |

Fig. 9: Game $G_{6}$ and game $G_{7}$ for the proof of Theorem 2

| $\underline{\mathcal{A}\left(1^{\lambda}, p k\right)}$ |  |
| :---: | :---: |
| 1: $m^{*}, m_{1}^{*} \stackrel{\$}{\leftarrow} \mathcal{M} ; m_{0}=m^{*} ; m_{1}=m_{1}^{*}$ | $\underline{\mathrm{PCO}(m, c)}$ |
| $2: \quad b^{\prime \prime} \stackrel{\$}{\leftarrow}\{0,1\} ; r^{*} \stackrel{\$}{\leftarrow} \mathcal{R}$ | 1: $\quad$ if $m \notin \mathcal{M}$ |
| $3: \quad c^{*}=\operatorname{Enc}\left(p k, m_{b^{\prime \prime}} ; r^{*}\right)$ |  |
| 4: Pick a $2 q_{G}$-wise function $G$ | 3: else return |
| $5: \quad g(\cdot):=\operatorname{Enc}\left(p k, \cdot ; G \backslash m_{0}(\cdot)\right)$ |  |
| $6: \quad m^{\prime} \leftarrow \mathcal{B}^{G \backslash m_{0}, \mathrm{PCO}}\left(p k, c^{*}\right)$ |  |
| 7: Query $G$ with input $m^{\prime}$ |  |
| 8: return Find |  |

Fig. 10: Adversary $\mathcal{A}$ for the proof of Theorem 2

Finally, combing this with the bounds derived above, we can conclude that

$$
\operatorname{Adv}_{\mathrm{PKE}^{\prime}}^{\mathrm{OW}-q \mathrm{PCA}}(\mathcal{B}) \leq 4 q_{G} \sqrt{\delta}+2\left(q_{G}+2\right) \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}(\mathcal{A})+4 \frac{\left(q_{G}+2\right)^{2}}{|\mathcal{M}|}
$$

## C Auxiliary lemmas

We note that semi-classical OW2H lemma can not directly apply to the security proofs where underlying assumption is a search one (e.g., One-Wayness) since the semi-classical oracle can only return "Yes" (the event Find happens) or "no" (the event $\neg$ Find happens). Indeed, intuitively, if Find happens, we can measure the register $|x\rangle$ of the query state $\sum_{x, z: f_{S}(x)=1} a_{x, z}|x\rangle|z\rangle$ to obtain a $x$ such that $x \in S$.

Here, formally, we focus on the case where the set $S$ is a singleton, i.e., $S=\left\{x^{*}\right\}\left(x^{*} \in X\right)$ and slightly modify the semi-classical OW2H lemma to make it applicable for security proofs with a search assumption.

Semi-classical oracle with auxiliary extractor. An auxiliary extractor $L^{\prime}$ with size $\lceil\log |X|\rceil$ is added to record $x^{*}$. For a query to $O_{S}^{S C}$ with $\sum_{x, z} a_{x, z}|x\rangle|z\rangle$, $\mathcal{O}_{S}^{S C}$ does the following,

1. initialize a single qubit $L$ and an auxiliary extractor $L^{\prime}$ with $|0\rangle$,
2. transform $\sum_{x, z} a_{x, z}|x\rangle|z\rangle|0\rangle|0\rangle$ into $\sum_{x, z} a_{x, z}|x\rangle|z\rangle\left|f_{S}(x)\right\rangle\left|f_{S}^{\prime}(x)\right\rangle$, where $f_{S}^{\prime}(x)=x \cdot f_{S}(x)$, that is $f_{S}^{\prime}(x)=x$ if $x=x^{*}$ and 0 otherwise.
3. measure $L$ and $L^{\prime}$.

Note that the state of composite system made up of $L$ and $L^{\prime}$ is a superposition of $|0\rangle|0\rangle$ and $|1\rangle\left|x^{*}\right\rangle$. Thus, if the measurement of $L$ outputs 1 (0), the measurement of $L^{\prime}$ will output $x^{*}(0)$. Given $x^{*} \in X$, we can view the composite system of $L$ and $L^{\prime}$ as a new system $\tilde{L},|0\rangle|0\rangle$ as $|\tilde{0}\rangle,|1\rangle\left|x^{*}\right\rangle$ as $|\tilde{1}\rangle$. Thus, following the proof of $[20$, Theorem 1], we can directly derive the following lemma.

Lemma 5 (Semi-classical OW2H with auxiliary extractor). Let $S=$ $\left\{x^{*}\right\}\left(x^{*} \in X\right)$ be random. Let $\mathcal{O}_{1}, \mathcal{O}_{2}$ be oracles with domain $X$ and codomain $Y$ such that $\mathcal{O}_{1}(x)=\mathcal{O}_{2}(x)$ for any $x \neq x^{*}$. Let $z$ be a random bitstring. $\left(\mathcal{O}_{1}, \mathcal{O}_{2}\right.$, $S$ and $z$ may have arbitrary joint distribution D.) Let $\mathcal{O}_{S}^{S C}$ be a semi-classical oracle with auxiliary extractor described above. Let $\mathcal{O}_{2} \backslash S$ ("O $\mathcal{O}_{2}$ punctured on $S$ ") be an oracle that first queries $\mathcal{O}_{S}^{S C}$ and then $\mathcal{O}_{2}$.

Let $A^{\mathcal{O}_{1}}(z)$ be an oracle algorithm with query depth $q$. Denote Find as the event that in the execution of $A^{\mathcal{O}_{2} \backslash S}(z), \mathcal{O}_{S}^{S C}$ ever outputs 1 and $x^{*}$ during semi-classical measurements.

Let

$$
\begin{aligned}
P_{\text {left }} & :=\operatorname{Pr}\left[b=1:\left(\mathcal{O}_{1}, \mathcal{O}_{2}, S, z\right) \leftarrow D, b \leftarrow A^{\mathcal{O}_{1}}(z)\right] \\
P_{\text {right }} & :=\operatorname{Pr}\left[b=1:\left(\mathcal{O}_{1}, \mathcal{O}_{2}, S, z\right) \leftarrow D, b \leftarrow A^{\mathcal{O}_{2}}(z)\right] \\
P_{\text {find }} & :=\operatorname{Pr}\left[\text { Find }:\left(\mathcal{O}_{1}, \mathcal{O}_{2}, S, z\right) \leftarrow D, A^{\mathcal{O}_{2} \backslash S}(z)\right]
\end{aligned}
$$

Then $\left|P_{\text {left }}-P_{\text {right }}\right| \leq 2 \sqrt{(q+1) P_{\text {find }}}$ and $\left|\sqrt{P_{\text {left }}}-\sqrt{P_{\text {right }}}\right| \leq 2 \sqrt{(q+1) P_{\text {find }}}$. The lemma also holds with bound $\sqrt{(q+1) P_{\text {find }}}$ for the following alternative definition of $P_{\text {right }}$,

$$
P_{\text {right }}=\operatorname{Pr}\left[b=1 \wedge \neg \text { Find }:\left(\mathcal{O}_{1}, \mathcal{O}_{2}, S, z\right) \leftarrow D, b \leftarrow A^{\mathcal{O}_{2} \backslash S}(z)\right] .
$$

Lemma 6 ([11, Lemma 4][10, Lemma 2.2]). Let $\Omega_{H}\left(\Omega_{H^{\prime}}\right)$ be the set of all functions $H:\{0,1\}^{n_{1}} \times\{0,1\}^{n_{2}} \rightarrow\{0,1\}^{m}\left(H^{\prime}:\{0,1\}^{n_{2}} \rightarrow\{0,1\}^{m}\right)$. Let $H \stackrel{\$}{\leftarrow} \Omega_{H}, H^{\prime} \stackrel{\$}{\leftarrow} \Omega_{H^{\prime}}, x \stackrel{\$}{\leftarrow}\{0,1\}^{n_{1}}$. Let $F_{0}=H(x, \cdot), F_{1}=H^{\prime}(\cdot)$ Consider an oracle algorithm $A^{H, F_{i}}$ that makes at most $q$ queries to $H$ and $F_{i}(i \in\{0,1\})$. If $x$ is independent from the $A^{H, F_{i}}$ 's view,

$$
\left|\operatorname{Pr}\left[1 \leftarrow A^{H, F_{0}}\right]-\operatorname{Pr}\left[1 \leftarrow A^{H, F_{1}}\right]\right| \leq 2 q \frac{1}{\sqrt{2^{n_{1}}}}
$$

## D Improved security proofs for remaining (modular) FO transformations

## D. $1 \mathrm{FO}^{\perp}$ : From IND-CPA-secure PKE to IND-CCA-secure KEM

To a public-key encryption scheme $\operatorname{PKE}=(G e n, E n c, D e c)$ with message space $\mathcal{M}$, ciphertext space $\mathcal{C}$ and randomness space $\mathcal{R}$, hash functions $G: \mathcal{M} \rightarrow \mathcal{R}$ and $H: \mathcal{M} \times \mathcal{C} \rightarrow \mathcal{K}$, we associate $\mathrm{KEM}-\mathrm{II}=\mathrm{FO}^{\perp}[\mathrm{PKE}, G, H]$, see Fig. 11.

Different from the one in $\mathrm{FO}_{m}^{\perp}$, the random oracle $H$ in $\mathrm{FO}^{\nless}$ takes both the plaintext $m$ and the ciphertext $c$ as input. Using the same proof technique in [11, Theorem 1], we can divide the $H$-inputs $(m, c)$ into two categories, matched inputs and unmatched inputs, by judging whether $c=\operatorname{Enc}(p k, m ; G(m))$, and replace $H$ by $H_{q} \circ g$ only for the matched inputs. Then, following the proofs of Theorem 1, we can derive Theorem 3.

Fig. 11: IND-CCA-secure KEM-II $=\mathrm{FO} \not{ }^{\not}[\mathrm{PKE}, G, H]$

Theorem 3 (PKE IND-CPA $\stackrel{Q R O M}{\Rightarrow}$ KEM-II IND-CCA). If PKE is $\delta$ correct, for any IND-CCA $\mathcal{B}$ against KEM-II, issuing at most $q_{D}$ queries to
the decapsulation oracle DECAPS, at most $q_{G}\left(q_{H}\right)$ queries to the random oracle $G(H)$, there exists an IND-CPA adversary $\mathcal{A}$ against PKE such that
$\operatorname{Adv}_{\mathrm{KEM-II}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B}) \leq 2 q_{H} \frac{1}{\sqrt{|\mathcal{M}|}}+4 q_{G} \sqrt{\delta}+2 \sqrt{\left(q_{G}+q_{H}+1\right) \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}(\mathcal{A})+2 \frac{\left(q_{G}+q_{H}+1\right)^{2}}{|\mathcal{M}|}}$
and the running time of $\mathcal{A}$ is about that of $\mathcal{B}$.

## D. 2 TPunc: From IND-CPA-secure PKE to DS-secure DPKE

| $G e n^{\prime}$ | $\underline{D e c}(s k, c)$ | $\underline{S(p k)}$ |
| :---: | :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n$ | 1: $m^{\prime}:=\operatorname{Dec}(s k, c)$ | 1: $\quad r \stackrel{\$}{\leftarrow} \mathcal{R}$ |
| 2: return $(p k, s k)$ | $2: \quad$ if $m^{\prime} \notin \mathcal{M}^{\prime}$ | 2: c $\quad$ = Enc $(p k, 0 ; r)$ |
|  | 3: return $\perp$ | 3: return $c$ |
| $\underline{E n c}{ }^{\prime}(p k, m)$, where $m \in \mathcal{M}^{\prime}$ | 4: else return $m^{\prime}$ |  |
| 1: $c=\operatorname{Enc}(p k, m ; G(m))$ |  |  |
| 2: return $c$ |  |  |

Fig. 12: DS-secure $\mathrm{PKE}^{\prime}=\mathrm{TPunc}[\mathrm{PKE}, G]$ with simulation $S$

The transformation TPunc that converts a perfectly-correct IND-CPA-secure PKE into a DS-secure DPKE, is a variant of T and proposed by [10]. The security of TPunc is proven in the QROM with non-tight reduction due to the usage of OW2H lemma. Here, we will improve the reduction using semi-classical OW2H lemma.

To a $\mathrm{PKE}=(G e n, E n c, D e c)$ with message space $\mathcal{M}$ and randomness space $R$, and a random oracle $G: \mathcal{M} \rightarrow \mathcal{R}$, we associate $\mathrm{PKE}^{\prime}=\left(G e n^{\prime}, E n c^{\prime}, D e c^{\prime}\right)=$ TPunc $[\operatorname{PKE}, G]$, where $\mathcal{M}^{\prime}=\mathcal{M} \backslash\{0\}$, see Fig. 12 .

Theorem 4 (PKE IND-CPA $\stackrel{Q R O M}{\Rightarrow} \mathbf{P K E}^{\prime}$ DS). Let $S$ be the algorithm described in Fig. 12. Let $U_{\mathcal{M}^{\prime}}$ be the uniform distribution over $\mathcal{M}^{\prime}$. If PKE is perfectly correct, $\mathrm{DISJ}_{\mathrm{PKE}^{\prime}, S}=0$. Moreover, for any $\mathcal{B}$ against PKE issuing at most $q_{G}$ quantum queries to $G$, there exist adversaries $\mathcal{A}_{1}$ and $\mathcal{A}_{2}$ against the IND-CPA security of PKE such that $\operatorname{Adv}_{\mathrm{PKE}^{\prime}, U_{\mathcal{M}^{\prime}}, S}^{\mathrm{DS}}(\mathcal{B}) \leq 2 \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}\left(\mathcal{A}_{2}\right)+$ $2 \sqrt{2\left(q_{G}+1\right) \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}\left(\mathcal{A}_{1}\right)+4 \frac{\left(q_{G}+1\right)^{2}}{|\mathcal{M}|}}$, and the running time of $\mathcal{A}_{1}\left(\mathcal{A}_{2}\right)$ is about that of $\mathcal{B}$.

Remark: In [14], TPunc is modularized into two transformations, Punc (reduce IND-CPA security to probabilistic DS security tightly) and T (reduce probabilistic DS security to deterministic DS security non-tightly). The proof technique in Theorem 4 can also be trivially used to get a tighter reduction for T from probabilistic DS security to deterministic DS security.

Proof. $\mathrm{DisJ}_{\mathrm{PKE}^{\prime}, S}=0$ has been proven in [10, Theorem 3.3]. Here, we focus on the upper bound of $\operatorname{Adv}_{\mathrm{PKE}^{\prime}, U_{\mathcal{M}^{\prime}}, S}^{\mathrm{DS}}(\mathcal{B})$. Let $\mathcal{B}$ be an adversary against $\mathrm{PKE}^{\prime}$,
issuing at most $q_{G}$ queries to the random oracle $G$. Denote $\Omega_{G}$ as the sets of all functions $G: \mathcal{M} \rightarrow \mathcal{R}$.

| GAMES $G_{0}$ | GAMES $G_{1}-G_{2}$ |
| :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n ; G \stackrel{\$}{\leftarrow} \Omega_{G}$ | 1: $\quad(p k, s k) \leftarrow G e n ; G \stackrel{\$}{\leftarrow} \Omega_{G}$ |
| 2: $\quad r^{*} \stackrel{\oiint}{\leftarrow}$ | 2: $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}^{\prime}$ |
| 3: $\quad c^{*}:=\operatorname{Enc}\left(p k, 0 ; r^{*}\right)$ | $3: \quad r^{*}:=G\left(m^{*}\right) / / G_{1}$ |
| 4: $\quad b^{\prime} \leftarrow \mathcal{B}^{G}\left(p k, c^{*}\right)$ | 4: $\quad r^{*} \stackrel{\$}{\leftarrow} \mathcal{R} / / G_{2}$ |
| $5:$ return $b^{\prime}$ | $5: \quad c^{*}:=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right)$ |
|  | $6: \quad b^{\prime} \leftarrow \mathcal{B}^{G}\left(p k, c^{*}\right)$ |
|  | 7: return $b^{\prime}$ |

Fig. 13: Games $G_{0}-G_{2}$ for the proof of Theorem 4

$$
\begin{array}{ll}
\mathcal{A}_{2} & \text { against the IND-CPA game } \\
\hline 1: & (p k, s k) \leftarrow G e n \\
2: & m_{0} \stackrel{\$}{\leftarrow} \mathcal{M}^{\prime} ; m_{1}:=0 \\
3: & r^{*} \stackrel{\$}{\leftarrow} \mathcal{R} ; b \stackrel{\$}{\leftarrow}\{0,1\} \\
4: & c^{*}:=E n c\left(p k, m_{b} ; r^{*}\right) \\
5: & b^{\prime} \leftarrow \mathcal{A}\left(p k, c^{*}\right) \\
6: & \text { return } b^{\prime}=? b
\end{array}
$$

| GAMES $G_{3}$ | GAMES $G_{4}$ |
| :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n ; G \stackrel{\$}{\leftarrow} \Omega_{G}$ | 1: $(p k, s k) \leftarrow G e n ; G \stackrel{\&}{\leftarrow} \Omega_{G}$ |
| 2: $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}^{\prime}$ | 2: $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}^{\prime}$ |
| 3: $\quad r^{*}:=G\left(m^{*}\right)$ | $3: \quad r^{*}:=G\left(m^{*}\right)$ |
| 4: $\quad \ddot{G}=G$ | 4: $\quad \ddot{G}=G$ |
| 5: $\ddot{G}\left(m^{*}\right) \stackrel{\$}{\stackrel{~}{*}}$ | 5: $\ddot{G}\left(m^{*}\right) \stackrel{\$}{\stackrel{~}{*}}$ |
| $6: \quad c^{*}:=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right)$ | $6: \quad c^{*}:=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right)$ |
| $7: \quad b^{\prime} \leftarrow \mathcal{B}^{\ddot{G}}\left(p k, c^{*}\right)$ | $7: \quad b^{\prime} \leftarrow \mathcal{B}^{\ddot{G} \backslash m^{*}}\left(p k, c^{*}\right)$ |
| 8: return $b^{\prime}$ | 8: return $b^{\prime}$ |

Fig. 15: Games $G_{3}-G_{4}$ for the proof of Theorem 4

Define games $G_{0}$ and $G_{1}$ as in Fig. 13. According to the definition of DS security, we have

$$
\operatorname{Adv}_{\mathrm{PKE}^{\prime}, U_{\mathcal{M}^{\prime}, S}}^{\mathrm{DS}-\mathrm{B}}(\mathcal{B})=\left|\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]\right|
$$

Game $G_{2}$. Replace $r^{*}:=G\left(m^{*}\right)$ by $r^{*} \stackrel{\$}{\leftarrow} \mathcal{R}$. First, as [10, Theorem 3.3] has showed, we can construct an adversary $\mathcal{A}_{2}$ against the IND-CPA security of PKE as in Fig. 14. Apparently,

$$
\left|\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]\right|=2 \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}\left(\mathcal{A}_{2}\right)
$$

Then, we will use semi-classical OW2H lemma to bound $\left|\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]\right|$.
 Then, it's easy to see that $G_{2}$ can be rewritten as $G_{3}$ in Fig. 15 and we have

$$
\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Pr}\left[G_{3}^{\mathcal{B}} \Rightarrow 1\right]
$$

Game $G_{4} . G_{4}$ is the same as $G_{3}$ except that $\ddot{G}$ is replaced by a semi-classical oracle $\ddot{G} \backslash m^{*}$. For a query input, $\ddot{G} \backslash m^{*}$ will first query $\mathcal{O}_{m^{*}}^{S C}$, i.e., perform a semiclassical measurement, and then query $\ddot{G}$. Let Find be the event that $\mathcal{O}_{m^{*}}^{S C}$ ever outputs 1 during semi-classical measurements of the queries to $\ddot{G} \backslash m^{*}$.

Applying Lemma 3 with $X=\mathcal{M}, Y=\mathcal{R}, S=\left\{m^{*}\right\}, \mathcal{O}_{1}=G, \mathcal{O}_{2}=\ddot{G}$ and $z=\left(p k, c^{*}\right)$, we can have

$$
\left|\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{3}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq 2 \sqrt{\left(q_{G}+1\right) \operatorname{Pr}\left[\text { Find }: G_{4}\right]}
$$

We note that in game $G_{4}, G\left(m^{*}\right)$ is only used in evaluating $c^{*}$ and independent of $\ddot{G}$, we can replace $r^{*}:=G\left(m^{*}\right)$ by $r^{*} \stackrel{\$ \mathcal{R}}{\leftarrow}$ and then simplify $G_{4}$ as $G_{5}$ in Fig. 16. Since the output distributions of $G_{4}$ and $G_{5}$ are totally identical, we have

$$
\operatorname{Pr}\left[G_{4}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Pr}\left[G_{5}^{\mathcal{B}} \Rightarrow 1\right]
$$

| GAMES $G_{5}-G_{6}$ | GAMES $G_{7}$ |
| :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n ; G \stackrel{\$}{\leftarrow} \Omega_{G}$ | 1: $\quad(p k, s k) \leftarrow G e n ; G \stackrel{\$}{\leftarrow} \Omega_{G}$ |
| 2: $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}^{\prime} / / G_{5}$ | 2: $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}$ |
| 3: $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M} / / G_{6}$ | 3: $m_{1}^{*} \stackrel{\$}{\leftarrow} \mathcal{M}$ |
| 4: $\quad r^{*} \stackrel{\$}{\leftarrow} \mathcal{R}$ | 4: $\quad r^{*} \stackrel{\$}{\leftarrow}$ |
| $5: \quad c^{*}:=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right)$ | $5: \quad c^{*}:=\operatorname{Enc}\left(p k, m_{1}^{*} ; r^{*}\right)$ |
| $6: \quad b^{\prime} \leftarrow \mathcal{B}^{G \backslash m^{*}}\left(p k, c^{*}\right)$ | $6: \quad b^{\prime} \leftarrow \mathcal{B}^{G \backslash m^{*}}\left(p k, c^{*}\right)$ |
| 7: return $b^{\prime}$ | $7: \quad$ return $b^{\prime}$ |

Fig. 16: Games $G_{5}-G_{7}$ for the proof of Theorem 4

Game $G_{6}$. In game $G_{6}$, we replace $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}^{\prime}$ by $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}$. Since the statistical distance between uniform distributions on $\mathcal{M}^{\prime}$ and $\mathcal{M}$ is $\frac{1}{|\mathcal{M}|}$, we have

$$
\left|\operatorname{Pr}\left[G_{5}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{6}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq \frac{1}{|\mathcal{M}|}
$$

Game $G_{7}$. In game $G_{7}$, we replace $c^{*}:=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right)$ by $c^{*}:=\operatorname{Enc}\left(p k, m_{1}^{*} ; r^{*}\right)$, where $m_{1}^{*} \stackrel{\$}{\leftarrow} \mathcal{M}$. Note that the information of $m^{*}$ in this game only exists in the oracle $G \backslash m^{*}$, by Lemma 4 we have

$$
\operatorname{Pr}\left[\text { Find }: G_{7}\right] \leq 4 \frac{q_{G}}{|\mathcal{M}|}
$$

$$
\begin{array}{ll}
\hline \mathcal{A}\left(1^{\lambda}, p k\right) \\
\hline 1: & m^{*}, m_{1}^{*} \stackrel{\oiint}{\leftarrow} \mathcal{M} \\
2: & m_{0}=m^{*} ; m_{1}=m_{1}^{*} \\
3: & b^{\prime \prime} \leftrightarrows\{0,1\} \\
4: & r^{*} \stackrel{\perp}{\leftarrow} \mathcal{R} \\
5: & c^{*}=E n c\left(p k, m_{b^{\prime \prime}} ; r^{*}\right) \\
6: & \text { Pick a } 2 q_{G} \text {-wise function } G \\
7: & m^{\prime} \leftarrow \mathcal{B}^{G \backslash m_{0}}\left(p k, c^{*}\right) \\
8: & \text { return Find }
\end{array}
$$

Fig. 17: Adversary $\mathcal{A}_{1}$ for the proof of Theorem 4

Next, we show that any adversary distinguishing $G_{6}$ from $G_{7}$ can be converted into an adversary against the IND-CPA security of underlying PKE. Construct an adversary $\mathcal{A}_{1}$ on input $\left(1^{\lambda}, p k\right)$ as in Fig. 17, where Find returns 1 iff the event Find that $\mathcal{O}_{m_{0}}^{S C}$ ever outputs 1 during semi-classical measurements happens. Then, according to Lemma 1 , if $b^{\prime \prime}=0, \mathcal{A}_{1}$ perfectly simulates $G_{6}$ and $\operatorname{Pr}\left[\right.$ Find $\left.: G_{6}\right]=\operatorname{Pr}\left[1 \leftarrow \mathcal{A}_{1}: b^{\prime \prime}=0\right]$. If $b^{\prime \prime}=1$, $\mathcal{A}$ perfectly simulates $G_{7}$ and $\operatorname{Pr}\left[\right.$ Find $\left.: G_{7}\right]=\operatorname{Pr}\left[1 \leftarrow \mathcal{A}_{1}: b^{\prime \prime}=1\right]$. Since $\operatorname{Adv}_{\operatorname{PKE}}^{\mathrm{IND}-\operatorname{CPA}}(\mathcal{A})=$ $1 / 2\left|\operatorname{Pr}\left[1 \leftarrow \mathcal{A}_{1}: b^{\prime \prime}=0\right]-\operatorname{Pr}\left[1 \leftarrow \mathcal{A}_{1}: b^{\prime \prime}=1\right]\right|$,

$$
\mid \operatorname{Pr}\left[\text { Find }: G_{6}\right]-\operatorname{Pr}\left[\text { Find }: G_{7}\right] \mid=2 \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}\left(\mathcal{A}_{1}\right)
$$

Finally, combing this with the bounds derived above, we have $\operatorname{Adv}_{\mathrm{PKE}^{\prime}, U_{\mathcal{M}^{\prime}}, S}^{\mathrm{DS}} \mathrm{IN}^{\prime}(\mathcal{B})$

$$
\begin{aligned}
& \leq 2 \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}\left(\mathcal{A}_{2}\right)+2 \sqrt{2\left(q_{G}+1\right) \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}\left(\mathcal{A}_{1}\right)+4 \frac{\left(q_{G}+1\right) q_{G}}{|\mathcal{M}|}+\frac{q_{G}+1}{|\mathcal{M}|}} \\
& \leq 2 \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}\left(\mathcal{A}_{2}\right)+2 \sqrt{2\left(q_{G}+1\right) \operatorname{Adv}_{\mathrm{PKE}}^{\mathrm{IND}-\mathrm{CPA}}\left(\mathcal{A}_{1}\right)+4 \frac{\left(q_{G}+1\right)^{2}}{|\mathcal{M}|}}
\end{aligned}
$$

## D. 3 KC: from OW-CPA-secure DPKE to DS-secure DPKE

Following the idea of "plaintext confirmation" that attaches an additional hash of plaintext to ciphertext, [10] proposed a transformation KC from OW-CPASecure DPKE to DS-Secure DPKE. The security reduction of KC in the QROM is non-tight due to the usage of OW2H lemma. Here, we will use semi-classical OW2H lemma to improve the tightness in [10].

| $G e n^{\prime}$ | $\operatorname{Dec}^{\prime}(s k, c)$ | $S(p k)$ |
| :---: | :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n$ | 1: Parse $c=\left(c_{1}, c_{2}\right)$ | 1: $m \stackrel{\$}{\leftarrow} \mathcal{M}$ |
| 2: return $(p k, s k)$ | 2: $\quad m^{\prime}:=\operatorname{Dec}\left(s k, c_{1}\right)$ | $2: \quad c_{1}=\operatorname{Enc}(p k, m)$ |
| $\underline{E n c}{ }^{\prime}(p k, m)$ | $\begin{array}{ll} 3: & \text { if } m^{\prime} \notin \mathcal{M} \vee H\left(m^{\prime}\right) \neq c_{2} \\ 4: & \text { return } \perp \end{array}$ | $3: \quad c_{2} \stackrel{\$}{\leftarrow}\{0,1\}^{n}$ |
| 1: $c_{1}=\operatorname{Enc}(p k, m)$ | 5 : else return $m^{\prime}$ |  |
| $2: \quad c_{2}=H(m)$ |  |  |
| 3: return $c=\left(c_{1}, c_{2}\right)$ |  |  |

Fig. 18: DS-secure $\mathrm{DPKE}^{\prime}=\mathrm{KC}[\mathrm{DPKE}, H]$ with simulation $S$

To a public-key encryption DPKE $=(G e n, E n c, D e c)$ with message space $\mathcal{M}$, and a random oracle $H: \mathcal{M} \rightarrow\{0,1\}^{n}$, we associate $\mathrm{DPKE}^{\prime}=\left(G e n^{\prime}, E n c^{\prime}, D e c^{\prime}\right)=$ KC[DPKE, $H$ ], see Fig. 18.

## Theorem 5 (DPKE OW-CPA $\stackrel{Q R O M}{\Rightarrow}{ }^{\text {DPKE }}$ DS). Let $S$ be the algorithm

 described in Fig. 18. If DPKE is perfectly correct, DISJ DPKE $^{\prime}, S=2^{-n}$. Moreover, for any $\mathcal{B}$ against $D P K E^{\prime}$ issuing at most $q_{H}$ quantum queries to $H$, there exists an adversary $\mathcal{A}$ against the $O W-C P A$ security of DPKE such that $\operatorname{Adv}_{\mathrm{DPKE}^{\prime}, U_{\mathcal{M}}, S}^{\mathrm{DS}-\mathrm{IND}}(\mathcal{B}) \leq 2 \sqrt{\left(q_{H}+1\right) \operatorname{Adv}_{\mathrm{DPKE}}^{\mathrm{OW}-\mathrm{CPA}}(\mathcal{A})}$ and the running time of $\mathcal{A}$ is about that of $\mathcal{B}$.Proof. Since $H$ is a random oracle, it's obvious that $\operatorname{DisJ}_{\mathrm{DPKE}^{\prime}, S}=2^{-n}$.
Let $\Omega_{H}$ be the sets of all functions $H: \mathcal{M} \rightarrow\{0,1\}^{n}$. Define game $G_{0}$ and game $G_{1}$ as in Fig. 19. Then, we have

$$
\operatorname{Adv}_{\mathrm{DPKE}^{\prime}, U_{\mathcal{M}}, S}^{\mathrm{DS}-\mathrm{IND}}(\mathcal{B})=\left|\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]\right|
$$

Let $\ddot{H}$ be the function such that $\ddot{H}(m)=H(m)$ for $m \neq m^{*}$ and $\ddot{H}\left(m^{*}\right) \stackrel{\$}{\leftarrow} \mathcal{R}$. Then, it's easy to see that $G_{1}$ can be rewritten as $G_{2}$ in Fig. 20 and we have

$$
\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]
$$

Game $G_{3} . G_{3}$ is the same as $G_{2}$ except that $\ddot{H}$ is replaced by a semi-classical oracle $\ddot{H} \backslash m^{*}$. For a query input, $H \backslash m^{*}$ will first query $\mathcal{O}_{m^{*}}^{S C}$, i.e., perform a semi-classical measurement, and then query $\ddot{H}$. Particularly, $\mathcal{O}_{m^{*}}^{S C}$ here will be equipped with an auxiliary extractor to record $m^{*}$. Let Find be the event that $\mathcal{O}_{m *}^{S C}$ ever outputs 1 and $m^{*}$ during semi-classical measurements of the queries to $\ddot{H} \backslash m^{*}$.

Fig. 20: Games $G_{2}-G_{3}$ for the proof of Theorem 5

Applying Lemma 5 with $X=\mathcal{M}, Y=\mathcal{R}, S=\left\{m^{*}\right\}, \mathcal{O}_{1}=H, \mathcal{O}_{2}=\ddot{H}$ and $z=\left(p k, c^{*}\right)$, we can have

$$
\left|\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq 2 \sqrt{\left(q_{G}+1\right) \operatorname{Pr}\left[\text { Find }: G_{3}\right]}
$$

Note that in game $G_{3}, H\left(m^{*}\right)$ is only used in evaluating $c_{2}^{*}$ and independent of $\ddot{H}$, we can replace $c_{2}^{*}:=H\left(m^{*}\right)$ by $c_{2}^{*} \leftarrow\{0,1\}^{n}$ and then simplify $G_{3}$ as $G_{4}$ in Fig. 21. Since the output distributions of $G_{3}$ and $G_{4}$ are totally identical, we
have

$$
\operatorname{Pr}\left[\text { Find }: G_{3}\right]=\operatorname{Pr}\left[\text { Find }: G_{4}\right] .
$$

Next, construct an adversary $\mathcal{A}\left(p k, c_{1}^{*}\right)$ against the OW-CPA security of underlying DPKE as in Fig. 21, where $\hat{H} \backslash m^{*}$ is the same as $H \backslash m^{*}$ except that the indication function $f_{m^{*}}(m)$ which outputs 1 if $m=m^{*}$ and 0 otherwise, is replaced by $\hat{f}_{m^{*}}(m)$,

$$
\hat{f}_{m^{*}}(m)=\left\{\begin{array}{cc}
1 & \operatorname{Enc}(p k, m)=c^{*} \\
0 & \text { otherwise }
\end{array}\right.
$$

Note that $\operatorname{Enc}(p k, m)=c^{*}$ iff $m=m^{*}$ since PKE is perfectly correct. Thus, $\hat{H} \backslash m^{*}$ is totally identical with $H \backslash m^{*}$. According to Lemma 1,

$$
\operatorname{Pr}\left[\text { Find }: G_{4}\right]=\operatorname{Adv}_{\mathrm{DPKE}}^{\mathrm{OW}-\mathrm{CPA}}(\mathcal{A}) .
$$

| GAMES $G_{4}$ | $\mathcal{A}\left(p k, c_{1}^{*}\right)$ |
| :---: | :---: |
| 1: $(p k, s k) \leftarrow G e n^{\prime} ; H \stackrel{\$}{\leftarrow} \Omega_{H}$ | 1: $c_{2}^{*} \stackrel{\$}{\leftarrow}\{0,1\}^{n}$ |
| 2: $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}$ | $2: \quad c^{*}=\left(c_{1}^{*}, c_{2}^{*}\right)$ |
| $3: \quad c_{1}^{*}:=\operatorname{Enc}\left(p k, m^{*}\right)$ | 3: Pick a $2 q_{H}$-wise function $H$ |
| 4: $c_{2}^{*} \stackrel{\$}{\leftarrow}\{0,1\}^{n}$ | $4: \quad b^{\prime} \leftarrow \mathcal{B}^{\hat{H} \backslash m^{*}}\left(p k, c^{*}\right)$ |
| $5: \quad c^{*}=\left(c_{1}^{*}, c_{2}^{*}\right)$ | 5 : return Find |
| $6: \quad b^{\prime} \leftarrow \mathcal{B}^{H \backslash m^{*}}\left(p k, c^{*}\right)$ |  |
| 7: return $b^{\prime}$ |  |

Fig. 21: Game $G_{4}$ and $\mathcal{A}$ for the proof of Theorem 5

Collecting all above bounds, we have

$$
\operatorname{Adv}_{\mathrm{DPKE}}, U_{\mathcal{M}}, S(\mathcal{B}) \leq 2 \sqrt{\left(q_{H}+1\right) \operatorname{Adv}_{\mathrm{DPKE}}^{\mathrm{OW}-\mathrm{IND}}(\mathcal{A})}
$$

Fig. 22: IND-CCA-secure KEM-III $=U \not{ }^{\not}\left[\mathrm{PKE}^{\prime}, H\right]$

## D. $4 \mathrm{U}^{\searrow}$ : from OW-qPCA-secure PKE to IND-CCA-secure KEM

To a public-key encryption $\mathrm{PKE}^{\prime}=\left(G e n^{\prime}, E n c^{\prime}, D e c^{\prime}\right)$ and a random oracle $H$ $(H: \mathcal{M} \times \mathcal{C} \rightarrow \mathcal{K})$, we associate KEM-III $=U^{X}\left[\mathrm{PKE}^{\prime}, H\right]$. The algorithms of KEM-III $=($ Gen,Encaps,Decaps $)$ are defined in Fig. 22.

Theorem 6 ( $\mathbf{P K E}^{\prime}$ OW-qPCA $\stackrel{Q R O M}{\Rightarrow}$ KEM IND-CCA). If $P K E^{\prime}$ is $\delta$ correct, for any IND-CCA $\mathcal{B}$ against KEM-III, issuing at most $q_{D}$ (classical) queries to the decapsulation oracle DECAPS and at most $q_{H}$ queries to the quantum random oracle $H$, there exists a $O W-q P C A$ adversary $\mathcal{A}$ against PKE' such that $\operatorname{Adv}_{\mathrm{KEM}-\mathrm{III}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B}) \leq 2 q_{H} \frac{1}{\sqrt{|\mathcal{M}|}}+2 \sqrt{\left(q_{H}+1\right)\left(2 \delta+\operatorname{Adv}_{\mathrm{PKE}^{\prime}}^{\mathrm{OW}-q \mathrm{PCA}}(\mathcal{A})\right)}$ and the running time of $\mathcal{A}$ is about that of $\mathcal{B}$.

Proof. Let $\mathcal{B}$ be an adversary against the IND-CCA security of KEM-III, issuing at most $q_{D}$ queries to DECAPS and at most $q_{H}$ queries to $H$. Let $\Omega_{H}$ and $\Omega_{H_{q}}$ be the sets of all functions $H: \mathcal{M} \times \mathcal{C} \rightarrow \mathcal{K}$ and $H_{q}: \mathcal{C} \rightarrow \mathcal{K}$, respectively. Consider the games in Fig. 23 and Fig. 25.

Game $G_{0}$. Since game $G_{0}$ is exactly the IND-CCA game,

$$
\left|\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]-1 / 2\right|=\operatorname{Adv}_{\mathrm{KEM}-\mathrm{III}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B}) .
$$

Game $G_{1}$. In game $G_{1}$, the Decaps oracle is changed that $H_{q}^{\prime}(c)$ is returned instead of $H(s, c)$ for an invalid encapsulation $c$. Considering that $\mathcal{B}$ 's view is independent of (the uniform secret) $s$, we can use Lemma 6 to obtain

$$
\left|\operatorname{Pr}\left[G_{0}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq 2 q_{H} \cdot \frac{1}{\sqrt{\mathcal{M}}}
$$

Game $G_{2}$. In game $G_{2}, H$ is changed that $H_{q}(c)$ is returned instead of $H_{1}(m, c)$ when $(m, c)$ satisfies $\operatorname{PCO}(m, c)=1$ (i.e., $\operatorname{Dec}^{\prime}(s k, c)=m$ ). Note that it is impossible that $\operatorname{PCO}\left(m_{1}, c\right)=\operatorname{PCO}\left(m_{2}, c\right)=1$ for $m_{1} \neq m_{2}$ because Dec is a deterministic algorithm. Further, as $H_{q}$ is a random function independent of $H_{1}, H$ in game $G_{2}$ is also a uniformly random function like the one in game $G_{1}$. Thus,

$$
\operatorname{Pr}\left[G_{1}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]
$$

Game $G_{3}$. In game $G_{3}$, the Decaps oracle is changed that it makes no use of the secret key $s k^{\prime}$ any more. When $\mathcal{B}$ queries the Decaps oracle on $c(c \neq$ $\left.c^{*}\right), K:=H_{q}(c)$ is returned as the response. In order to show that the output distributions of Decaps are identical in $G_{2}$ and $G_{3}$, we consider the following cases for a fixed ciphertext $c$ and $m^{\prime}:=\operatorname{Dec}^{\prime}(s k, c)$.

Fig. 23: Games $G_{0}-G_{5}$ for the proof of Theorem 6

Case 1: $m^{\prime} \neq \perp$. Note that $H\left(m^{\prime}, c\right)=H_{q}(c)$ on account of $\operatorname{PCO}\left(m^{\prime}, c\right)=1$. Therefore, the two Decaps oracles in games $G_{2}$ and $G_{3}$ return the same value.
Case 2: $m^{\prime}=\perp$. Random values $H_{q}^{\prime}(c)$ and $H_{q}(c)$ in $\mathcal{K}$ are returned in $G_{2}$ and $G_{3}$, respectively. In $G_{2}, H_{q}^{\prime}$ is a random function independent of $H$. In $G_{3}, \mathcal{B}$ 's queries to $H$ can only help him get access to $H_{q}$ at $c$ such that $\operatorname{Dec}^{\prime}(s k, c)=\hat{m}$ for some $\hat{m} \neq \perp$. Therefore, $\mathcal{B}$ never sees $H_{q}(c)$ by querying $H$. Hence, in $\mathcal{B}$ 's view, $H_{q}(c)$ is totally uniform at random like $H_{q}^{\prime}(c)$. As a result, the DECAPS oracle in $G_{3}$ has the same output distribution as the one in $G_{2}$.

Thus, $\mathcal{B}$ 's views are identical in $G_{2}$ and $G_{3}$ and we have

$$
\operatorname{Pr}\left[G_{2}^{\mathcal{B}} \Rightarrow 1\right]=\operatorname{Pr}\left[G_{3}^{\mathcal{B}} \Rightarrow 1\right]
$$

Let $\ddot{H}$ be an oracle such that $\ddot{H}(m, c)=H(m, c)$ for $(m, c) \neq\left(m^{*}, c^{*}\right)$ and

Game $G_{4}$. In game $G_{4}$, replace $H$ by $\ddot{H}$. We note that in this game $b$ is independent of $\mathcal{B}$ 's view since queries to $\ddot{H}$ and Decaps can not reveal $H\left(m^{*}, c^{*}\right)$. Thus,

$$
\operatorname{Pr}\left[G_{4}^{\mathcal{B}} \Rightarrow 1\right]=1 / 2
$$

Game $G_{5}$. In game $G_{5}$, replace $\ddot{H}$ by $\ddot{H} \backslash S$. Given any query input, $\ddot{H} \backslash S$ will first query semi-classical oracle $\mathcal{O}_{S}^{S C}$, i.e., perform a semi-classical measurement, and then query $\ddot{H}$. Particularly, $\mathcal{O}_{S}^{S C}$ here will be equipped with an auxiliary extractor to record $\left(m^{*}, c^{*}\right)$. Let Find be the event that $\mathcal{O}_{S}^{S C}$ ever outputs 1 and ( $m^{*}, c^{*}$ ) during semi-classical measurements of the queries to $\ddot{H} \backslash S$.

Let $A^{H}$ be an oracle algorithm on input $\left(p k, c^{*}, k_{0}^{*}, H_{q}\right)^{10}$ in Fig. 24. Sample $p k, c^{*}, k_{0}^{*}, H_{q}$ and $H$ in the same way as $G_{3}$ and $G_{4}$, i.e., $(p k, s k) \leftarrow G e n$, $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M}, r^{*} \stackrel{\$}{\leftarrow} \mathcal{R}, c^{*}=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right), H_{q} \stackrel{\$}{\leftarrow} \Omega_{H_{q}}, H_{1} \stackrel{\$}{\leftarrow} \Omega_{H}$, simulate $H$ in the same way as $G_{3}$ and $G_{4}$, set $k_{0}^{*}=H\left(m^{*}, c^{*}\right), \ddot{H}(m, c)=H(m, c)$ for $(m, c) \neq\left(m^{*}, c^{*}\right)$ and $\ddot{H}\left(m^{*}, c^{*}\right) \stackrel{\$}{\leftarrow} \mathcal{K}$. Then, $A^{H}$ and $A^{\ddot{H}}$ on input $\left(p k, c^{*}, k_{0}^{*}\right.$, $H_{q}$ ) perfectly simulate $G_{3}$ and $G_{4}$, respectively.

| $\frac{A^{H}\left(p k, c^{*}, k_{0}^{*}, H_{q}\right)}{}$ |  |  |  |
| :--- | :--- | :--- | :--- |
|  | $k_{1}^{*} \stackrel{\$}{\leftarrow} \mathcal{K}$ |  | $1: \quad$ return $K:=H_{q}(c)$ |
| $2:$ | $b \stackrel{\$}{\leftarrow}\{0,1\}$ |  |  |
| $3:$ | $b^{\prime} \leftarrow \mathcal{B}^{H, \text { DecAPs }}\left(p k, c^{*}, k_{b}^{*}\right)$ |  |  |
| $4:$ | return $b^{\prime}=? b$ |  |  |

Fig. 24: $A^{H}$ for the proof of Theorem 6.

| GAMES $G_{6}-G_{9}$ | $H(m, c)$ |
| :---: | :---: |
| 1: $\quad\left(p k, s k^{\prime}\right) \leftarrow G e n^{\prime}$ | 1: if $\mathrm{PCO}(m, c)=1$ |
| 2: $\quad H_{q} \stackrel{\$}{\leftarrow} \Omega_{H_{q}} ; H_{1} \stackrel{\$}{\leftarrow} \Omega_{H}$ | 2: return $H_{q}(c)$ |
| 3: $m^{*} \stackrel{\$}{\leftarrow} \mathcal{M} ; r^{*} \stackrel{\$}{\leftarrow} \mathcal{R}$ | 3: else return $H_{1}(m, c)$ |
|  | Decaps ( $c \neq c^{*}$ ) |
| $\begin{array}{ll} 4: & r^{*} \stackrel{\S}{\leftarrow} \mathcal{R}_{\text {good }}(p k, s k, m) / / G_{7}-G_{8} \\ 5: & c^{*}:=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right) \end{array}$ | 1: return $K:=H_{q}(c)$ |
| $6: \quad k_{0}^{*}, k_{1}^{*} \stackrel{\$}{\leftarrow} \mathcal{K} ; b \stackrel{\$}{\leftarrow}\{0,1\}$ |  |
| $7: \quad b^{\prime} \leftarrow B^{H \backslash\left(m^{*}, c^{*}\right), \mathrm{DeCaps}}\left(p k, c^{*}, k_{b}^{*}\right) / / G_{6}-G_{7}$ |  |
| $8: \quad b^{\prime} \leftarrow B^{\hat{H} \backslash\left(m^{*}, c^{*}\right), \text { Decaps }}\left(p k, c^{*}, k_{b}^{*}\right) / / G_{8}-G_{9}$ |  |
| 9: return $b^{\prime}=? b$ |  |

Fig. 25: Games $G_{6}-G_{9}$ for the proof of Theorem 6

[^4]Applying Lemma 5 with $X=(\mathcal{M}, \mathcal{C}), Y=\mathcal{K}, S=\left\{\left(m^{*}, c^{*}\right)\right\}, \mathcal{O}_{1}=H$, $\mathcal{O}_{2}=\ddot{H}$ and $z=\left(p k, c^{*}, k_{0}^{*}, H_{q}\right)$, we can have

$$
\left|\operatorname{Pr}\left[G_{3}^{\mathcal{B}} \Rightarrow 1\right]-\operatorname{Pr}\left[G_{4}^{\mathcal{B}} \Rightarrow 1\right]\right| \leq 2 \sqrt{\left(q_{H}+1\right) \operatorname{Pr}\left[\text { Find }: G_{5}\right]}
$$

Since $H\left(m^{*}, c^{*}\right)$ in $G_{5}$ is used only once and independent of the oracles $\ddot{H}$ and DECAPS, we can replace $k_{0}^{*}=H\left(m^{*}, c^{*}\right)$ by $k_{0}^{*} \stackrel{\$}{\leftarrow} \mathcal{K}$ and simplify $G_{5}$ into $G_{6}$ as in Fig. 25, and have

$$
\operatorname{Pr}\left[\text { Find }: G_{5}\right]=\operatorname{Pr}\left[\text { Find }: G_{6}\right]
$$

 $\mathcal{R}_{\text {good }}\left(p k, s k, m^{*}\right):=\left\{r \in \mathcal{R}: \operatorname{Dec}\left(s k, \operatorname{Enc}\left(p k, m^{*} ; r\right)\right)=m^{*}\right\}$ 。

We note that the statistical distance between uniform distributions on $\mathcal{R}$ and $\mathcal{R}_{\text {good }}\left(p k, s k, m^{*}\right)$ is

$$
\delta\left(p k, s k, m^{*}\right)=\frac{\left|\mathcal{R}_{\mathrm{bad}}\left(p k, s k, m^{*}\right)\right|}{|\mathcal{R}|}
$$

where $\mathcal{R}_{\text {bad }}\left(p k, s k, m^{*}\right)=\mathcal{R} \backslash \mathcal{R}_{\text {good }}\left(p k, s k, m^{*}\right)$. Let $\delta(p k, s k)=\max _{m \in \mathcal{M}} \delta(p k, s k, m)$. Then $\delta=\mathbf{E}[\delta(p k, s k)]$, where the expectation is taken over $(p k, s k) \leftarrow G e n$.

Conditioned on a fixed $(p k, s k)$ we have $\mid \operatorname{Pr}\left[\right.$ Find $\left.: G_{6}\right]-\operatorname{Pr}\left[\right.$ Find $\left.: G_{7}\right] \mid \leq$ $\delta(p k, s k)$. By averaging over $(p k, s k) \leftarrow G e n$ we finally obtain

$$
\mid \operatorname{Pr}\left[\text { Find }: G_{6}\right]-\operatorname{Pr}\left[\text { Find }: G_{7}\right] \mid \leq \delta
$$

Game $G_{8}$. In game $G_{8}$, replace $H \backslash S$ by $\hat{H} \backslash S$, where $\hat{H} \backslash S$ is the same as $H \backslash S$ except the indicator function $f_{S}(m, c)$ in semi-classical oracle $\mathcal{O}_{S}^{S C}$ is replaced by $\hat{f}_{S}(m, c) . \hat{f}_{S}(m, c)$ is defined as

$$
\hat{f}_{S}(m, c)=\left\{\begin{array}{cc}
1 & \mathrm{PCO}\left(m, c^{*}\right)=1 \text { and } c=c^{*} \\
0 & \text { otherwise }
\end{array}\right.
$$

We note that $f_{S}(m, c)=1 \mathrm{iff}(m, c)=\left(m^{*}, c^{*}\right)$. Since $c^{*}=\operatorname{Enc}\left(p k, m^{*} ; r^{*}\right)$ and the $r^{*}$ in this game is sampled from "good" randomness, $\operatorname{PCO}\left(m, c^{*}\right)=1 \mathrm{iff}$ $m=m^{*}$. Therefore, $f_{S}(m, c)$ is identical with $\hat{f}_{S}(m, c)$, and we have

| $\underline{\mathcal{A}\left(1^{\lambda}, p k, c^{*}\right)}$ | $\underline{H(m, c)}$ |
| :---: | :---: |
| $1: k_{0}^{*}, k_{1}^{*} \stackrel{\$}{\leftarrow}$ |  |
| 2: $\quad b \stackrel{\$}{\leftarrow}\{0,1\}$ | 1: if $\operatorname{PCO}(m, c)=1$ |
| 3: Pick a $q_{H}$-wise functions $H_{q}, H_{1}$ | 3: else return $H_{1}(m, c)$ |
| 4: $\quad m^{\prime} \leftarrow \mathcal{B}^{\text {fiS,DECAPS }}\left(p k, c^{*}\right)$ | DECAPS $\left(c \neq c^{*}\right)$ |
|  | 1: return $K:=H_{q}(c)$ |

Fig. 26: Adversary $\mathcal{A}$ for the proof of Theorem 6
 to the case of bounding the difference between $G_{6}$ and $G_{7}$, we can have

$$
\mid \operatorname{Pr}\left[\text { Find }: G_{8}\right]-\operatorname{Pr}\left[\text { Find }: G_{9}\right] \mid \leq \delta .
$$

Then, we construct an adversary $\mathcal{A}$ against the OW-qPCA security of the $\mathrm{PKE}^{\prime}$ scheme as in Fig. 26. According to Lemma 1,

$$
\operatorname{Adv}_{\mathrm{PKE}^{\prime}}^{\mathrm{OW}-q \mathrm{PCA}}(\mathcal{A})=\operatorname{Pr}\left[\text { Find }: G_{9}\right]
$$

Finally, combing this with the bounds derived above, we can conclude that

$$
\operatorname{Adv}_{\mathrm{KEM}-\mathrm{III}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B}) \leq 2 q_{H} \frac{1}{\sqrt{\mathcal{M}}}+2 \sqrt{\left(q_{H}+1\right)\left(2 \delta+\operatorname{Adv}_{\mathrm{PKE}^{\prime}}^{\mathrm{OW}-q \mathrm{PCA}}(\mathcal{A})\right)}
$$

## D. $5 \mathrm{U}^{\perp}$ : from OW-qPVCA-secure PKE to IND-CCA-secure KEM

$\mathrm{U}^{\perp}$, a KEM variant of the REACT/GEM transformations [8, 9], was first given by [3, Table 2]. To a public-key encryption $\mathrm{PKE}^{\prime}=\left(G e n^{\prime}, E n c^{\prime}, D e c^{\prime}\right)$ and a hash function $H$, we associate KEM-IV $=\mathrm{U}^{\perp}\left[\mathrm{PKE}^{\prime}, H\right]$ as in Fig. 27. The security of $\mathrm{U}^{\perp}$ in the QROM was analyzed by [11]. However, the security proof is nontight due to utilization of OW2H lemma. Here, using the semi-classical OW2H lemma in the same way as in Theorem 6, we improve the tightness and obtain the following theorem.

| Gen |  | Encaps (pk) |  | $\operatorname{Decaps}^{\perp}(s k, c)$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1: | $(p k, s k) \leftarrow G e n^{\prime}$ |  | $m \stackrel{\$}{\leftarrow} \mathcal{M}$ |  | $m^{\prime}:=\operatorname{Dec}^{\prime}(s k, c)$ |
|  | return $(p k, s k)$ | $2:$ | $c \leftarrow E n c^{\prime}(p k, m)$ | 2 : | if $m^{\prime}=\perp$ |
|  |  | $3:$ | $K:=H(m, c)$ | $3:$ | return $\perp$ |
|  |  |  | return $(K, c)$ |  | else return |
|  |  |  |  | 5 : | $K:=H\left(m^{\prime}, c\right)$ |

Fig. 27: IND-CCA-secure KEM-IV $=U^{\perp}\left[\mathrm{PKE}^{\prime}, H\right]$

Theorem 7 ( PKE $^{\prime}$ OW-qPVCA $\stackrel{Q R O M}{\Rightarrow}{ }^{\prime}$ KEM-IV IND-CCA). If $\mathrm{PKE}^{\prime}$ is $\delta$-correct, for any IND-CCA $\mathcal{B}$ against KEM-IV, issuing at most $q_{D}$ (classical) queries to the decapsulation oracle DECAPS and at most $q_{H}$ queries to the quantum random oracle $H$, there exists a $O W-q P V C A$ adversary $\mathcal{A}$ against $P K E^{\prime}$ that makes at most $q_{H}$ queries to the PCO oracle and at most $q_{D}$ (classical) queries to the VAL oracle such that $\operatorname{Adv}_{\mathrm{KEM}-\mathrm{IV}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B}) \leq 2 \sqrt{\left(q_{H}+1\right)\left(2 \delta+\operatorname{Adv}_{\mathrm{PKE}^{\prime}}^{\mathrm{OW}-q \mathrm{PVCA}}(\mathcal{A})\right)}$ and the running time of $\mathcal{A}$ is about that of $\mathcal{B}$.

## D. $6 \mathrm{U}_{m}^{\ngtr} / U_{m}^{\perp}$ : from OW-CPA-secure/OW-VA-secure DPKE to IND-CCA KEM

The transformation $\mathrm{U}_{m}^{\not \searrow}\left(\mathrm{U}_{m}^{\perp}\right)[27,4]$ is a variant of $\mathrm{U}^{\perp}\left(\mathrm{U}^{\perp}\right)$ that derives the KEM key as $K=H(m)$ instead of $K=H(m, c)$. To a deterministic public-key encryption scheme $\mathrm{PKE}^{\prime}=\left(G e n^{\prime}, E n c^{\prime}, D e c^{\prime}\right)$ with message space $\mathcal{M}$, a hash function $H: \mathcal{M} \rightarrow \mathcal{K}$, and a pseudorandom function $f$ with key space $\mathcal{K}^{p r f}$, we associate KEM-V $\left.=\mathrm{U}_{m}^{\not} \nmid \mathrm{DPKE}^{\prime}, H, f\right]$ and $\mathrm{KEM}-\mathrm{VI}=\mathrm{U}_{m}^{\perp}\left[\mathrm{DPKE}^{\prime}, H\right]$ shown in Fig. 28 and Fig. 29, respectively.

| Gen | $\operatorname{Encaps}(p k)$ | $\operatorname{Decaps}\left(s k^{\prime}, c\right)$ |
| :---: | :---: | :---: |
| $\begin{array}{ll} 1: & (p k, s k) \leftarrow G e n^{\prime} \\ 2: & k \stackrel{\$}{\leftarrow} \mathcal{K}^{p r f} \\ 3: & s k^{\prime}:=(s k, k) \\ 4: & \text { return }\left(p k, s k^{\prime}\right) \end{array}$ | $\begin{array}{ll} 1: & m \stackrel{\oiint}{\Perp} \\ 2: & c:=E n c^{\prime}(p k, m) \\ 3: & K:=H(m) \\ 4: & \text { return }(K, c) \end{array}$ | ```Parse \(s k^{\prime}=(s k, k)\) \(m^{\prime}:=\operatorname{Dec}^{\prime}(s k, c)\) if \(E n c^{\prime}\left(p k, m^{\prime}\right)=c\) return \(K:=H\left(m^{\prime}\right)\) else return \(K:=f(k, c)\)``` |

Fig. 28: IND-CCA-secure KEM-V $=\mathrm{U} \frac{1}{m}\left[\mathrm{DPKE}^{\prime}, H, f\right]$

| Gen | Encaps (pk) | $\operatorname{Decaps}(s k, c)$ |
| :---: | :---: | :---: |
| 1: $\quad(p k, s k) \leftarrow G e n^{\prime}$ | 1: $m \stackrel{\$}{\leftarrow} \mathcal{M}$ | 1: $m^{\prime}:=\operatorname{Dec}^{\prime}(s k, c)$ |
| 2: return $(p k, s k)$ | $2: \quad c:=E n c^{\prime}(p k, m)$ | 2: if $E n c^{\prime}\left(p k, m^{\prime}\right)=c$ |
|  | $3: \quad K:=H(m)$ | 3: return $K:=H\left(m^{\prime}\right)$ |
|  | 4: return $(K, c)$ | 4: else return $\perp$ |

Fig. 29: IND-CCA-secure $\mathrm{KEM}-\mathrm{VI}=\mathrm{U}_{m}^{\perp}\left[\mathrm{DPKE}^{\prime}, H\right]$

We note that for a deterministic PKE scheme the OW-PCA security is equivalent to the OW-CPA security as we can simulate the PCO oracle via reencryption during the proof. Thus, combing the proofs of Theorem 6, Theorem 7 , we can easily obtain the following two theorems.

Theorem 8 ( $\mathbf{P K E}^{\prime}$ OW-CPA $\stackrel{Q R O M}{\Rightarrow}$ KEM-V IND-CCA). If $\mathrm{PKE}^{\prime}$ is $\delta$ correct and deterministic, for any IND-CCA $\mathcal{B}$ against KEM-V, issuing at most $q_{D}$ (classical) queries to the decapsulation oracle DECAPS and at most $q_{H}$ quantum queries to the random oracle $H$, there exist a $O W-C P A$ adversary $\mathcal{A}$ against $\mathrm{PKE}^{\prime}$ and an adversary $\mathcal{A}^{\prime}$ against the security of PRF with at most $q_{D}$ classical queries such that $\operatorname{Adv}_{\mathrm{KEM-V}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B}) \leq 2 \sqrt{\left(q_{H}+1\right)\left(\operatorname{Adv}_{\mathrm{PKE}^{\prime}}^{\mathrm{OW}-\mathrm{CPA}}(\mathcal{A})+\delta\right)}+\delta+$ $\operatorname{Adv}_{\operatorname{PRF}}\left(\mathcal{A}^{\prime}\right)$, and the running time of $\mathcal{A}$ is about that of $\mathcal{B}$.

Theorem 9 ( $\mathbf{P K E}^{\prime}$ OW-VA $\stackrel{Q R O M}{\Rightarrow}$ KEM-VI IND-CCA). If $\mathrm{PKE}^{\prime}$ is $\delta$ correct and deterministic, for any IND-CCA $\mathcal{B}$ against KEM-VI, issuing at most $q_{D}$ (classical) queries to the decapsulation oracle DECAPS and at most $q_{H}$ quantum queries to the random oracle $H$, there exists a $O W$-VA adversary $\mathcal{A}$ against $\mathrm{PKE}^{\prime}$ who makes at most $q_{D}$ (classical) queries to the VAL oracle such that $\operatorname{Adv}_{\mathrm{KEM}-\mathrm{VI}}^{\mathrm{IND}-\mathrm{CCA}}(\mathcal{B}) \leq 2 \sqrt{\left(q_{H}+1\right)\left(\operatorname{Adv}_{\mathrm{PKE}^{\prime}}^{\mathrm{OW}-\mathrm{VA}}(\mathcal{A})+\delta\right)}+\delta$ and the running time of $\mathcal{A}$ is about that of $\mathcal{B}$.

[^0]:    ${ }^{5}$ The message $m$ here is picked at random from the message space of underlying PKE.
    ${ }^{6}$ When comparing the tightness of different reductions, we assume perfect correctness of underlying scheme for brevity.

[^1]:    ${ }^{7}$ Here, for TPunc and KC, we just follow [10] and assume the perfect correctness of underlying PKE.

[^2]:    ${ }^{8}$ Although $H_{q}$ here is the whole truth table of $H_{q}$, it is just taken as an oracle to make queries (with at most $q_{H}$ times) in algorithm $A$. Thus, we can also take $H_{q}$ as an accessible oracle instead of a whole truth table.

[^3]:    ${ }^{9}$ For a classical query input $m^{*}, \mathcal{O}_{m^{*}}^{S C}$ always outputs 1.

[^4]:    ${ }^{10}$ As in the proof of Theorem $1, H_{q}$ here can be either the whole truth table of $H_{q}$ or an accessible oracle.
