# Simulation-Extractable SNARKs Revisited <br> July 23, 2019 

Helger Lipmaa ${ }^{1,2}$<br>1 University of Tartu, Tartu, Estonia<br>2 Simula UiB, Bergen, Norway<br>helger.lipmaa@gmail.com

#### Abstract

The most efficient SNARKs (e.g., Groth, 2016) have a brittle and difficult-to-verify knowledge-soundness proof in the generic model. This makes it nontrivial to modify such SNARKs to, e.g., satisfy simulation-extractability or to implement some other language instead of QAP (Quadratic Arithmetic Program). We propose knowledgesound and non-black-box strong any-simulation-extractable (SASE) subversion-zero knowledge SNARKs for QAP that is designed to have a relatively simple security proof. The knowledge-sound SNARK is similar to the mentioned SNARK of Groth, except it has fewer trapdoors. To achieve SASE, we add to it a one-time simulation-extractable QA-NIZK for a subspace language. Moreover, we give a simple characterization of languages like SAP, SSP, and QSP in the terms of QAP and show how to modify the SNARK for QAP correspondingly. The only prior published efficient simulation-extractable SNARK was for the somewhat impractical SAP language. We prove soundness under subversion algebraic knowledge assumptions that are a concrete version of the (subversion) algebraic group model.

Keywords: Algebraic group model, NIZK, non-black-box, QAP, QSP, SNARK, SAP, SSP, simulation-extractability, subversion zero-knowledge

## 1 Introduction

Zero-knowledge proof systems [GMR85] are fundamental for the theory and applications of cryptography. In particular, zero-knowledge proof systems are used to guarantee that participants of some protocol follow the protocol correctly. For zero-knowledge proof systems to be used in practice, one needs an "efficient" zero-knowledge proof system that satisfies "reasonable" security definitions under "reasonable" cryptographic and trust assumptions. Due to their performance and versatility, zero-knowledge succinct non-interactive arguments of knowledge (zkSNARKs, Gro10 BCCT12 Lip12 GGPR13|PHGR13 BCCT13 Lip13 Gro16]) have become one of the most widely researched and deployed proof systems, in particular because of their applicability in verifiable computation [PHGR13] and anonymous cryptographic currencies DFKP13 $\mathrm{BCG}^{+} 14$. The mentioned zk-SNARKs are knowledge-sound in the CRS model BFM88.

It is difficult to design SNARKs, and it is easy for even well-established research groups to err in such an endeavor (see, e.g., Par15CGGN17Gab19 for related cryptanalysis). One explanation for this is that for the proof system to be secure, one needs to carefully designed the constant number of proof elements and verification equations o that they satisfy a number of properties:

First, they need to encode an NP language. The most widely used language is that of a quadratic arithmetic program (QAP, GGPR13) which corresponds to the rank-1 quadratic constraint system of the popular libSNARK library. Other related languages are square arithmetic programs (SAP, Gro16|GM17), quadratic span programs (QSP, GGPR13 Lip13), and square span programs (SSP, DFGK14). Here, QSP and SSP (resp., SAP and QAP) are convenient in the case one works with Boolean (resp., arithmetic) circuits.

Second, for optimal efficiency, the NP witness and the argument need to be encoded into the smallest number of proof elements and verified via the smallest number of verification equations possible. This creates a new set of design constraints, and several (tight) lower bound are known, Gro16GM17.

Third, throughout this process, one needs to assure that the SNARK remains (at least) knowledge-sound and zero-knowledge. Due to known impossibility results GW11, one has to use non-falsifiable assumptions like the knowledge assumptions Dam92. To facilitate better efficiency, the most efficient zk-SNARKs like Gro16] are proven to be knowledge-sound in the generic model. Generic model proofs often require one to derive soundness from a solution of a complicated system of polynomial equations. Moreover, there exist constructions that are secure in the generic group model but cannot be instantiated given any efficient instantiation of the group encoding [Fis00 Den02].

Fourth, sometimes, knowledge-soundness is not sufficient and one desires to achieve simulation-extractability (SE, Sah99 DDO ${ }^{+}$01 GM17). SE SNARKs guarantee that knowledge-soundness holds even after the adversary has seen many simulated proofs, a property that is needed in many applications including UC-security [Can01.

It has been studied how to achieve UC-security for SNARKs. Kosba et al. $\mathrm{KZM}^{+} 15$ constructed a black-box simulation-extractable version of SNARKs; black-box simulation-extractability is sufficient to obtain UCsecurity, Gro06. However, their transformation results in quite a large overhead and, in particular, results in a linear-size commitment. Alternatively, Groth and Maller GM17 proposed a non-black-box strong any-simulationextractable (SASE) SNARK that is only slightly less efficient than the most efficient knowledge-sound SNARK of Groth Gro16. However, their SNARK is based on the SAP language Gro16GM17 and thus has a blowup of approximately two times in circuit size compared to the QAP language. (This is since SAP has an efficient reduction from arithmetic circuits that have squaring gates instead of general multiplication gates, Gro16GM17.) They also proved that their construction achieved the lower bound for the argument length for SASE SNARKs. While SASE is not sufficient to obtain UC-security, it is clearly a stronger security notion than knowledge-soundness. Based on this observation,

Baghery Bag19] recently noticed that a much simpler transformation is needed to obtain UC-security based on SASE SNARKs. However, due to the use of SAP, this transformation is twice as costly when using the Groth-Maller SNARK as compared to (yet unknown) SASE SNARKs for QAP.

No other simulation-extractable SNARKs are known at this moment (except BG18 that works in the random-oracle model), not even ones that are just non-black-box ASE (any-simulation-extractable, allows an adversary after seeing simulation queries to modify a valid argument to a different valid argument for the same statement) or non-black-box TSE (any-simulation-extractable, allows an adversary after seeing simulation queries to true statement to modify a valid argument to a different valid argument for the same statement). This brings us to the main question of this paper:

> Is it possible to construct a general SNARK for a multitude of languages (like QAP, SAP, QSP, and SSP) that would simultaneously (i) satisfy SASE, (ii) have a simple soundness proof that does not use the whole power of the generic model, and (iii) be almost as efficient as the most efficient known knowledge-sound SNARKs.

Our Contributions. We answer positively to the main question. The new knowledge-sound zk-SNARK $\mathrm{S}_{\text {qap }}$ for QAP is similar to Groth's SNARK Gro16 while the SASE version $S_{\text {qap }}^{s e}$ of it is obtained from it by well-motivated modifications. Based on a simple observation about algebraic relations (summarized in Table 2) between QAP and other languages, we modify both $S_{\text {qap }}$ and $S_{\text {qap }}^{\text {se }}$ to cover SAP, QSP, and SSP. See Table 1 for an efficiency comparison ${ }^{3}$

Since the new SASE SNARKs are tag-based and maliciously chosen tags can depend on the group elements, we use (tautological) knowledge assumptions instead of the full-blown generic group model (GGM, Nec94Sho97) to prove knowledge-soundness and SASE. We motivate these knowledge assumptions by analysing the algebraic group model (AGM, [FKL18]): essentially, AGM states that for any efficient algorithm $\mathcal{A}$ that on an input vector $[\boldsymbol{x}]_{\iota}$ of group elements outputs an output vector $[\boldsymbol{y}]_{\iota}$ of group elements (we use here the bracket notation of $\mathrm{EHK}^{+} 13$ ), there exists an efficient extractor $\mathrm{Ext}_{\mathcal{A}}$ that outputs a matrix $\boldsymbol{N}$ such that $\boldsymbol{y}=\boldsymbol{N} \boldsymbol{x}$.

A tautological algebraic knowledge (AK) assumption, see Section 3, states that the same holds only for a concrete distribution of $[\boldsymbol{x}]_{\iota}$ (e.g., the distribution of correctly formed CRSs). In Section 3, we will also study a "subversion" BFS16] version SAK of the AK assumption: it is essentially an AGM version of the subversion generic model [SPMS02|BFS16|ABLZ17] where we require the extractor to output a matrix $\boldsymbol{N}$ and a vector of group elements $[\boldsymbol{q}]_{1}$, such that $\boldsymbol{y}=\boldsymbol{N}\binom{\boldsymbol{x}}{\boldsymbol{q}}$.
${ }^{3}$ We emphasize that it is only fair to compare SNARKs for the same language; to compare SNARKs for different languages, one also has to take into account the complexity of the reduction from circuits to these languages. Note that Lip13 only described a reduction from Boolean circuits to QSP and a linear PCP [ $\mathrm{BCI}^{+} 13$ ] for QSP, leaving out cryptographic details of constructing a SNARK.

Table 1. Efficiency comparison of QAP/SAP/SSP/QSP-based SNARKs. $m$ (or $\tilde{m}$ ) and $n$ (or $\tilde{n}$ ) denote the number of wires and gates (or constraints) in the solutions. " $\mathfrak{e}_{\iota}$ " (" $\mathfrak{m}_{\iota}$ ") denotes exponentiation (multiplication) in group $\mathbb{G}_{\iota}$, " $\mathfrak{p}$ " denotes pairing, and $\mathfrak{g}_{\iota}$ denotes the representation length of a $\mathbb{G}_{\iota}$ element in bits. In the case of |crs| and P's computation we omit constant (or $m_{0}$-dependent) addends like $+\left(m_{0}+3\right) \mathfrak{g}_{1}$.

Here, $[\boldsymbol{q}]_{1}$ are elements for which the adversary does not know discrete logarithm. In the new SNARKs, to be able to rely on an SAK assumption, we need $[\boldsymbol{q}]_{1}$ to come from a distribution of high min-entropy.

Similarly to subversion generic model and subversion algebraic model, a SAK assumption can explain the absence of attacks on existing efficient cryptographic protocols as they are, without having to decrease efficiency to obtain security under more standard assumptions like the knowledge-of-exponent assumptions Dam92 or falsifiable assumptons. On the other hand, using a SAK assumption as compared to the generic model enables one to handle a larger variety of protocols (e.g., tag-based or protocols where one employs hashing from group elements to integers) and avoids some of the criticisms against the generic model [Fis00 Den02]. Thus, arguably, SAK assumptions hit a sweet spot, being minimal assumptions to prove security of maximally efficient protocols.

In Section 4, we propose a knowledge-sound zk-SNARK $\mathrm{S}_{\text {qap }}$ for QAP. Recall that that the prover is honest (the statement belongs to the QAP language) iff $\chi(X):=u(X) v(X)-w(X)-h(X) \ell(X)=0$ (see GGPR13) for some polynomial $h(X)$, where the polynomials $u(X), v(X)$, and $w(X)$ depend on the concrete circuit and on the witness the prover is using, $\ell(X)$ is a public fixed polynomial.

We consider polynomials $A(X, Y), B(X, Y)$ ("commitments" to $u(X)$ and $v(X)$, respectively), and $C(X, Y)=A(X, Y) B(X, Y)$, such that the coefficient of $Y^{\kappa}$ (for a $\kappa$ fixed later) in $C(X, Y)$ is $u(X) v(X)-w(X)=h(X) \ell(X)$ for some $h(X)$ iff the prover is honest, i.e., $\chi(X)=0$. One can guarantee that $\chi(X)=0$ in the case of an algebraic adversary by inserting to the CRS elements of type [ $\left.f(x) y^{\kappa}\right]_{1}$ only for polynomials $f(X)$ that divide by $\ell(X)$. On top of it, $\mathrm{S}_{\text {qap }}$ needs to guarantee that (i) $u(X), v(X)$, and $w(X)$ use the same witness, and (ii) the public input encoded into $u(X)$ is correct.

We use aggressive optimization to get an as efficient SNARK as possible while not sacrificing (much) in the simplicity of the knowledge-soundness proof. Somewhat surprisingly, $\mathrm{S}_{\text {qap }}$ is very similar to Groth's SNARK from EUROCRYPT 2016 Gro16. However, it uses only two trapdoors instead of five. This distinction is important: for example, as noted in ABLZ17 Fuc18, only two out of Groth's five trapdoors are needed for simulation; thus, it is logical or at least aesthetic to drop the other trapdoors. In $\mathrm{S}_{\text {qap }}$, we use well-chosen powers of one trapdoor $Y$ as substitutes of four out of the five trapdoors of Groth's SNARK.

The way we choose the powers of $Y$ is interesting by itself. Let $\boldsymbol{X}^{*}=(X, \ldots)$ be the vector of all indeterminates, except $Y$, that are relevant in the knowledgesoundness (or SASE) proof. This includes $X, Y$, indeterminates created by the adversary by using elliptic curve hashing [ca09, and (in the case of SASE) indeterminates created by simulator queries. Then, $V\left(\boldsymbol{X}^{*}, Y\right)=\sum V_{i}\left(\boldsymbol{X}^{*}\right) Y^{i}$ for known polynomials $V_{i}\left(\boldsymbol{X}^{*}\right)$, where $i$ is a linear combination of an initially undetermined integer vector $\boldsymbol{\Delta}=(\alpha, \beta, \ldots)$. We show that in the case of $\mathrm{S}_{\text {qap }}$, a generic prover is honest iff $V_{i}\left(\boldsymbol{X}^{*}\right)=0$ for six critical values $i$. We then choose $\boldsymbol{\Delta}$ so that the corresponding six critical linear combinations $i$ are distinct from each other and from all other non-critical linear combinations $j$. Moreover, we choose $\boldsymbol{\Delta}$ so that the SNARK is relatively efficient. E.g., we require that for all critical $i,|i|$ is as small as possible, and check if there is a way to make some non-critical values $j$ to collapse (this can shorten the CRS). Since this is a moderately hard optimization problem for humans, we here use an exhaustive computer search. Due to this, exponents in the resulting SNARKs may look somewhat obscure.

In Section 5, we modify $\mathrm{S}_{\text {qap }}$ to make it SASE. We establish that for any $k$, a SASE adversary has an attack vector by setting $A(X, Y)=s_{a 1 k} D_{k}+\ldots$ for non-zero $s_{a 1 k}$, where $D_{k}$ is indeterminate generated during the $k$ th simulation query. We eliminate this attack vector by letting the prover to use an efficient quasi-adaptive NIZK (QA-NIZK, JR13) to prove that $A(X, Y)$ is in the span of correct monomials. Since our goal is simulation-extractability, the QA-NIZK has to be simulation-extractable. While known (unbounded) simulation-extractable QA-NIZKs are not very efficient, we observe that $S_{\text {qap }}$ itself (without the added QA-NIZK) already guarantees that an acceptable argument can only depend on the answer of a single simulation query. Thus, quite surprisingly, it is sufficient to use a more efficient one-time simulation-extractable (OTSE) QA-NIZK. It is known how to construct the latter efficiently KW15] by using tags. We construct an even more efficient OTSE QA-NIZK by relying on the specifics of $\mathrm{S}_{\text {qap }}$ and on non-falsifiable assumptions. Adding this QA-NIZK increases the complexity of
the SNARK only slightly compared to $\mathrm{S}_{\text {qap }}$ (see Table1). Since the Groth-Maller SASE zk-SNARK GM17 is for SAP, the new SASE SNARK is more efficient.

Importantly, $\mathrm{S}_{\text {qap }}$ has a simple Sub-GBGM knowledge-soundness proof where only the value of the six critical coefficients of $V$ matters. The SASE proof of the SASE SNARK relies only a few more extra coefficients. This should be compared to Groth's SNARK Gro16] (resp., the Groth-Maller SNARK GM17]) that has a very complicated knowledge-soundness (resp., SASE) proof.

As we mentioned before, $\mathrm{S}_{\text {qap }}$ is very similar to Groth's SNARK. We obtain a simpler knowledge-soundness proof by assuming that the pairing is asymmetric. (Asymmetric pairings are much more efficient than symmetric pairings and thus strongly preferred in practice.) On the other hand, Groth proved knowledgesoundness in the case of a symmetric pairing, which results in $A\left(\boldsymbol{X}^{*}, Y\right)$, $B\left(\boldsymbol{X}^{*}, Y\right)$, and $C\left(\boldsymbol{X}^{*}, Y\right)$ having more terms and thus $V\left(\boldsymbol{X}^{*}, Y\right)$ having more critical coefficients. Thus, one corollary of our knowledge-sound proof is the (up to our knowledge, novel) observation that Groth's SNARK has a very simple knowledge-soundness proof given that one uses asymmetric pairings. Our goal was not to duplicate Groth's SNARK but to construct an efficient SNARK that has a simple knowledge-soundness proof. Thus, our exposition of the derivation of $\mathrm{S}_{\text {qap }}$ can also be seen as an intuitive pedagogical re-derivation of (a slight variant of) the most efficient existing pairing-based SNARK. We emphasize that, on the other hand, $S_{\text {qap }}^{s e}$ is novel. In particular, none of the previous simulationextractable SNARKs [GM17BG18] used tags.

After that, we consider languages SAP Gro16GM17, SSP DFGK14, and QSP GGPR13 Lip13 that have also been used in the pairing-based SNARK literature. We explain their algebraic relation to QAP, which helps us to lift both $\mathrm{S}_{\text {qap }}$ and $\mathrm{S}_{\text {qap }}^{s e}$ to the setting of the corresponding languages. In the previous research, all four languages are handled separately and our (simple) relation seems to be novel. In some of the cases, we improve on the efficiency of previous known SNARKs for the same language. We propose the first known SASE SNARKs for QAP, SSP, and SAP. In particular, we propose the first known (efficient) SASE SNARKs for Boolean circuits in general. We omit precise descriptions of the reduction between circuits and corresponding languages, giving only a brief explanation and then referring to original papers.

In Section 6, we describe a SNARK $\mathrm{S}_{\text {sap }}$ for the language SAP (Square Arithmetic Program, GM17]). As mentioned before, SAP has an efficient reduction from arithmetic circuits that use squaring gates instead of multiplication gates. Thus, one has to take into account that such a circuit has usually two times more gates and wires, since in general one needs two squaring gates to implement a multiplication gate. This is a difference in the reduction overhead between circuits and the corresponding language, not in the cryptographic construction of the SNARK. Algebraically, SAP is a variant of QAP with $v(X)=u(X)$; thus, $\chi(X)=u(X)^{2}-w(X)-h(X) \ell(X)$. Thus, $\mathrm{S}_{\text {sap }}$ itself is as efficient as $\mathrm{S}_{\mathrm{qap}}$. Since the honest argument contains $\left([\mathrm{a}]_{1},[\mathrm{~b}]_{2}\right)$ with $\mathrm{a}=\mathrm{b}$, we obtain a SASE SNARK $S_{\text {sap }}^{\text {se }}$ by using a simpler tranformation than we used in the case of QAP.

Table 2. Algebraic relations between languages: restrictions on $u(X), v(X)$, and $v(X)$

| $u(X) \quad v(X) \quad w(X)$ |
| :---: |
| QAP general general general |
| SAP general $=u(X)$ general |
| SSP general $=u(X)=u(X)$ |
| QSP general general $=0$ |

In Section 7, we describe a SNARK $\mathrm{S}_{\text {ssp }}$ for the SSP language DFGK14 that has efficient reduction from Boolean Circuit-SAT. Algebraically, SSP is a variant of QAP, where one sets $u(X)=v(X)=w(X)$. Then, $\chi(X)=$ $u(X)(u(X)-1)-h(X) \ell(X) . \mathrm{S}_{\text {ssp }}$ is approximately as efficient as the SSP-based SNARK of DFGK14] but it has a shorter argument with more efficient verification (only one verification equation instead of two). The new SASE SNARK $\mathrm{S}_{\text {ssp }}^{\text {se }}$ for SSP uses the same transformation as $\mathrm{S}_{\text {sap }}^{\text {se }}$; no previous SASE SNARKs for SSP were known. We are not aware of a previous observation that one can design SNARKs for SSP by starting with a SNARK for QAP and then just setting $u(X)=v(X)=w(X)$.

We emphasize that an efficient SNARK for SSP is well-suited in applications where one needs to use Boolean circuits. They are also useful in applications like shuffle arguments [FLZ16|FLSZ17], and SSP has been used as the basis for falsifiable SNARKs with long commitments DGP ${ }^{+} 19$.

Finally, in Section 8, we design a SNARK for QSP (Quadratic Span Programs, GGPR13 Lip13). Algebraically, QSP is a variant of QAP, where one sets $w(X)=0$. QSP is interesting in theory since one can construct a 2-query linear PCP for it, $\left[\mathrm{BCI}^{+} 13 \mathrm{Lip} 13\right.$. However, the reduction from Boolean circuits to QSP is relatively complex, with the need to implement span-program-based gate checkers and error-correcting-code-based wire checkers GGPR13Lip13. The new SASE SNARK $S_{\text {qsp }}^{s e}$ for $Q S P$ uses the same transformation as $S_{\text {qap }}^{s e}$. $\mathrm{S}_{\text {qsp }}$ is again more efficient than previously known knowledge-sound SNARKs for QSP, while there was no previously known SASE SNARK for QSP.

To construct eight different SNARKs and verify their sets of critical coefficients and also soundness, we used computer algebra and exhaustive search. We believe that the soundness of the SNARKs is obvious, assuming that the variables $\boldsymbol{\Delta}=(\alpha, \beta, \ldots)$ have been chosen so that exponents of $Y$ corresponding to the critical coefficients are different from all other exponents. However, finding small values of these variables seems to require exhaustive search - the number of non-zero coefficients of $V_{i}\left(\boldsymbol{X}^{*}\right)$ (even in the knowledge-soundness proof and without allowing the algebraic adversary to create new indeterminates) is at least 30, depending on the SNARK. This issue can be solved by using more trapdoors as in Gro16, but such a solution is not always acceptable.

In Section 9, we show that $\mathrm{S}_{\text {qap }}$ and $\mathrm{S}_{\text {qap }}^{\text {se }}$ can be made subversion-zero knowledge (Sub-ZK, BFS16|ABLZ17|Fuc18]). Recall that a Sub-ZK SNARK remains zero knowledge even if the CRS creator was malicious. According to the template
of ABLZ17, one can deal with it by constructing a public CRS verification algorithm that checks that the CRS corresponds to some trapdoor, and then use a knowledge assumption to recover the trapdoor and simulate the argument. As explained in ALSZ18, Sub-ZK is equivalent to no-auxiliary-string non-black-box zero knowledge in the weak bare public key (BPK, [CGGM00 MR01]) model. Hence, $\mathrm{S}_{\text {qap }}^{\text {se }}$ is a simulation-extractable (no-auxiliary-string non-black-box) zkSNARK in the BPK model.

## 2 Preliminaries

For a matrix $\boldsymbol{A}, \boldsymbol{A}_{i}$ denotes its $i$ th row and $\boldsymbol{A}^{(j)}$ denotes its $j$ th column.
Assume $n$ is a power of two, and let $\omega$ be the $n$-th primitive root of unity modulo $p$. Such $\omega$ exists, given that $n \mid(p-1)$. Then, $\ell(X):=\prod_{i=1}^{n}\left(X-\omega^{i-1}\right)$ is the unique degree $n$ monic polynomial such that $\ell\left(\omega^{i-1}\right)=0$ for all $i \in[1 . . n]$. For $i \in[1 . . n]$, let $\ell_{i}(X)$ be the $i$ th Lagrange basis polynomial, i.e., the unique degree $n-1$ polynomial s.t. $\ell_{i}\left(\omega^{i-1}\right)=1$ and $\ell_{i}\left(\omega^{j-1}\right)=0$ for $i \neq j$. Given $\chi \in \mathbb{Z}_{p}$, there is an efficient algorithm (see, e.g., $\mathrm{BCG}^{+13}$ ) that computes $\ell_{i}(\chi)$ for $i \in[1 . . n]$. Clearly, $L_{\boldsymbol{a}}(X):=\sum_{i=1}^{n} a_{i} \ell_{i}(X)$ is the interpolating polynomial of $\boldsymbol{a}$ at points $\omega^{i-1}$, with $L_{\boldsymbol{a}}\left(\omega^{i-1}\right)=a_{i}$, and its coefficients can thus be computed by executing an inverse Fast Fourier Transform in time $\Theta(n \log n)$. Moreover, $\left(\ell_{j}\left(\omega^{i-1}\right)\right)_{i=1}^{n}=\boldsymbol{e}_{j}$ (the $j$ th unit vector) and $\left(\ell\left(\omega^{i-1}\right)\right)_{i=1}^{n}=\mathbf{0}_{n}$.

Let PPT denote probabilistic polynomial-time and let $\lambda \in \mathbb{N}$ be the security parameter. For an algorithm $\mathcal{A}$, range $(\mathcal{A})$ is the range of $\mathcal{A}$, i.e., the set of of valid outputs of $\mathcal{A}, \operatorname{RND}(\mathcal{A})$ denotes the random tape of $\mathcal{A}$, and $r \leftarrow \& \operatorname{RND}(\mathcal{A})$ denotes the uniformly random choice of the randomizer $r$ from $\operatorname{RND}(\mathcal{A})$. By $y \leftarrow \mathcal{A}(\mathrm{x} ; r)$ we denote the fact that $\mathcal{A}$, given an input x and a randomizer $r$, outputs $y$. Let negl $(\lambda)$ be an arbitrary negligible function, and poly $(\lambda)$ be an arbitrary polynomial function. We write $a \approx_{\lambda} b$ if $|a-b| \leq \operatorname{negl}(\lambda)$.

Bilinear Groups. A bilinear group generator $\operatorname{Pgen}\left(1^{\lambda}, n\right)$ returns $\left(p, \mathbb{G}_{1}, \mathbb{G}_{2}, \mathbb{G}_{T}, \hat{e}\right)$, where $\mathbb{G}_{1}, \mathbb{G}_{2}$, and $\mathbb{G}_{T}$ are three additive cyclic groups of prime order $p$, and $\hat{e}: \mathbb{G}_{1} \times \mathbb{G}_{2} \rightarrow \mathbb{G}_{T}$ is a non-degenerate efficiently computable bilinear pairing. We assume that $n \mid(p-1)$. As in say BFS16, we assume that Pgen is deterministic and cannot be subverted. We require the bilinear pairing to be Type-3 GPS08, i.e., we assume that there is no efficient isomorphism between $\mathbb{G}_{1}$ and $\mathbb{G}_{2}$. At this moment, the curve BLS12381 BLS04Bow17 is recommended at the 128-bit security level. We use the bracket notation of $\mathrm{EHK}^{+13}$, i.e., we write $[a]_{\iota}$ to denote $a g_{\iota}$ where $g_{\iota}$ is a fixed generator of $\mathbb{G}_{\iota}$. We denote $\hat{e}\left([a]_{1},[b]_{2}\right)$ by $[a]_{1} \bullet[b]_{2}$. We use freely the bracket notation together with matrix notation, e.g., $\boldsymbol{A B}=\boldsymbol{C}$ iff $[\boldsymbol{A}]_{1} \bullet[\boldsymbol{B}]_{2}=[\boldsymbol{C}]_{T}$.

Let $d_{1}(n), d_{2}(n) \in \operatorname{poly}(\lambda)$. Then, Pgen is $\left(d_{1}(n), d_{2}(n)\right)-P D L$ (Power Discrete Logarithm, Sta08 THS 09 JR10 Lip12] secure if for any non-uniform PPT adversary $\mathcal{A}, \operatorname{Adv}_{d_{1}, d_{2}, \operatorname{Pgen}, \mathcal{A}}^{\mathrm{pdl}}(\lambda)=\operatorname{negl}(\lambda)$, where $\operatorname{Adv}_{d_{1}, d_{2}, \operatorname{Pgen}, \mathcal{A}}^{\mathrm{pdl}}(\lambda):=$

$$
\operatorname{Pr}\left[\mathrm{p} \leftarrow \operatorname{Pgen}\left(1^{\lambda}, n\right), x \leftarrow \mathbb{\mathbb { Z }} \mathbb{Z}_{p}^{*}: \mathcal{A}\left(\mathrm{p} ;\left[\left(x^{i}\right)_{i=0}^{d_{1}(n)}\right]_{1},\left[\left(x^{i}\right)_{i=0}^{d_{2}(n)}\right]_{2}\right)=x\right] .
$$

The $q$-PDL assumption in $\mathbb{G}_{1}$ (resp., $\mathbb{G}_{2}$ ) is equal to the $(q, 0)$-PDL (resp., $(0, q)$ PDL) assumption.

QAP. Quadratic Arithmetic Program (QAP) was introduced in GGPR13 as a language where for an input $x$ and witness inp, $(x, i n p) \in \mathbf{R}$ can be verified by using a parallel quadratic check. QAP has an efficient reduction from the (either Boolean or Arithmetic) Circuit-SAT. Thus, an efficient zk-SNARK for QAP results in an efficient zk-SNARK for Circuit-SAT.

Let $m_{0}<m$ be a non-negative integer. In the case of arithmetic circuits, $n$ is the number of multiplication gates, $m$ is the number of wires, and $m_{0}$ is the number of public inputs. We consider arithmetic circuits that consist only of fan-in-2 multiplication gates, but either input of each multiplication gate can be any weighted sum of wire values, GGPR13.

Let $\mathbb{F}=\mathbb{Z}_{p}$, such that $\omega$ is the $n$-th primitive root of unity modulo $p$. This requirement is needed for the sake of efficiency, and we will make it implicitly throughout the paper. However, it is not needed for the new SNARKs to work. A QAP is characterized by $n$ constraints $\left(\sum_{j=1}^{m} U_{i j} u_{j}(X)\right)\left(\sum_{j=1}^{m} V_{i j} u_{j}(X)\right)=$ $\sum_{j=1}^{m} W_{i j} w_{j}(X)$, where $\boldsymbol{U}, \boldsymbol{V}$, and $\boldsymbol{W}$ are instant-dependent matrices. For $j \in$ $[1 \ldots m]$, define $u_{j}(X):=L_{\boldsymbol{U}^{(j)}}(X), v_{j}(X):=L_{\boldsymbol{V}^{(j)}}(X)$, and $w_{j}(X):=L_{\boldsymbol{W}^{(j)}}(X)$ to be interpolating polynomials of the $j$ th column of the corresponding matrix. Thus, $u_{j}, v_{j}, w_{j} \in \mathbb{Z}_{p}^{(\leq n-1)}[X]$.

An QAP instance $\operatorname{Inst}_{\text {qap }}$ is equal to $\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}, v_{j}, w_{j}\right\}_{j=0}^{m}\right)$. This instance defines the following relation:

$$
\mathbf{R}_{\text {lnst }_{\text {qap }}}=\left\{\begin{array}{l}
(\mathrm{x}, \mathrm{inp}): \mathrm{x}=\left(a_{1}, \ldots, a_{m_{0}}\right)^{\top} \wedge \mathrm{inp}=\left(a_{m_{0}+1}, \ldots, a_{m}\right)^{\top} \wedge  \tag{1}\\
u(X) v(X) \equiv w(X) \quad(\bmod \ell(X))
\end{array}\right\}
$$

where $u(X)=\sum_{j=0}^{m} a_{j} u_{j}(X), v(X)=\sum_{j=0}^{m} a_{j} v_{j}(X)$, and $w(X)=$ $\sum_{j=0}^{m} a_{j} w_{j}(X)$. Alternatively, $(x, \operatorname{inp}) \in \mathbf{R}$ if there exists a (degree $\left.\leq n-2\right)$ polynomial $h(X)$, such that the following key equation holds:

$$
\begin{equation*}
\chi(X):=u(X) v(X)-w(X)-h(X) \ell(X)=0 \tag{2}
\end{equation*}
$$

On top of checking Eq. (22, the verifier also needs to check that $u(X), v(X)$, and $w(X)$ are correctly computed: that is, that (i) the first $m_{0}$ coefficients $a_{j}$ in $u(X)$ are equal to the public inputs, and (ii) $u(X), v(X)$, and $w(X)$ are all computed by using the same coefficients $a_{j}$ for $j \leq m$.

SNARKs. Let $\mathcal{R}$ be a relation generator, such that $\mathcal{R}\left(1^{\lambda}\right)$ returns a polynomialtime decidable binary relation $\mathbf{R}=\{(\mathrm{x}, \mathrm{inp})\}$. Here, x is a statement and inp is a witness. We assume that $\lambda$ is explicitly deductible from the description of $\mathbf{R}$. $\mathcal{R}$ also outputs auxiliary information $\operatorname{aux}_{\mathbf{R}}$ that will be given to the honest parties and the adversary. As in Gro16], aux $\mathbf{x}_{\mathbf{R}}$ will be equal to $\mathrm{p} \leftarrow \operatorname{Pgen}\left(1^{\lambda}, n\right)$ for a well-defined $n$. Because of this, we will also give $\operatorname{aux}_{\mathbf{R}}$ as an input to the honest parties; if needed, one can include an additional auxiliary input as an input to
the adversary. We recall that the choice of $p$ and thus of the groups $\mathbb{G}_{z}$ depends on $n$. Let $\mathcal{L}_{\mathbf{R}}=\{\mathrm{x}: \exists \mathrm{inp},(\mathrm{x}, \mathrm{inp}) \in \mathbf{R}\}$ be an $\mathbf{N P}$-language.

We will define tag-based MY04 argument systems; in the non-tag-based case, the tag-space is Tags $=\{\epsilon\}$ (empty string) and tags are ignored by all algorithms. A non-interactive zero-knowledge (NIZK) argument system $\Psi=$ ( $\mathrm{K}_{\mathrm{cr}}, \mathrm{P}, \mathrm{V}, \mathrm{Sim}$ ) for $\mathcal{R}$ consists of four PPT algorithms:

CRS generator: $\mathrm{K}_{\text {crs }}$ is a probabilistic algorithm that, given $\left(\mathbf{R}, \mathrm{aux}_{\mathbf{R}}\right) \in$ range $\left(\mathcal{R}\left(1^{\lambda}\right)\right.$ ), outputs (crs, td) where crs is a CRS and td is a simulation trapdoor. Otherwise, it outputs a special symbol $\perp$. For the sake of efficiency and readability, we divide crs into crsp (the part needed by the prover) and crsv (the part needed by the verifier).
Prover: P is a probabilistic algorithm that, given ( $\mathbf{R}$, aux $_{\mathbf{R}}, \mathrm{crs}_{\mathrm{P}}, \tau, \mathrm{x}$, inp) for $\tau \in$ Tags and $(\mathrm{x}, \mathrm{inp}) \in \mathbf{R}$, outputs an argument $\pi$. Otherwise, it outputs $\perp$.
Verifier: V is a probabilistic algorithm that, given $\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}, \operatorname{crs} \mathrm{V}, \tau, \mathrm{x}, \pi\right)$, returns either 0 (reject) or 1 (accept).
Simulator: Sim is a probabilistic algorithm that, $\operatorname{given}\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}, \operatorname{crs}, \operatorname{td}, \tau, x\right)$, outputs an argument $\pi$.

A NIZK argument system must satisfy completeness (an honest verifier accepts an honest verifier), knowledge-soundness (if a prover makes an honest verifier accept, then one can extract from the prover a witness inp), and zero-knowledge (there exists a simulator that, knowing CRS trapdoor but not the witness, can produce accepting statements with the verifier's view being indistinguishable from the view when interacting with an honest prover). See Appendix A. 1 for formal definitions. A SNARK (succinct non-interactive argument of knowledge) is a NIZK argument system where the argument is sublinear in the input size.

Simulation-Extractability (SE). SE Sah99 DDO ${ }^{+}$01 is a stronger notion of knowledge-soundness, motivated by cryptographic applications like nonmalleability and UC-security. An SE argument system remains knowledge-sound even if the soundness adversary has access to the simulation oracle. More precisely, one requires that there exists a universal extractor Ext, such that for each PPT soundness adversary $\mathcal{A}$ who has oracle access to the simulator, Ext can deduce the witness from $\mathcal{A}$.

Dodis et al. DHLW10 differentiated between several favors of SE. In the case of any-simulation-extractability (ASE), the simulator can be queried with any (potentially false) statements while in the case of true-simulation-extractability (TSE), the simulator can only be queried with true statements. In the case of strong any-simulation-extractability, the adversary wins even if she can come up with a new argument for a statement she has queried a simulation for, as long as she outputs it for a new tag not used in simulation queries.

Groth and Maller GM17 introduced the notion of non-black-box simulation-extractability for SNARKs. In the case of non-black-box simulationextractability, one requires that for each PPT soundness adversary $\mathcal{A}$ who has oracle access to the simulator, there exists a non-black-box extractor Ext $\mathcal{A}_{\mathcal{A}}$ that
can extract the witness from $\mathcal{A}$. The definition of SE from GM17 corresponds to non-black-box strong any-simulation extractability (SASE). Since we are interested in non-black-box SE, we will implicitly assume SE means non-black-box SE.Groth and Maller proved that for any SASE SNARK, the argument consists at least of three group elements and that there should be at least two verification equations. They also proposed one concrete SASE SNARK, based on the SAP (Square Arithmetic Program) language, that meets the lower bounds. We will design several SASE SNARKs based on different languages like QAP GGPR13], SSP DFGK14, SAP Gro16, and QSP GGPR13. We will provide formal definitions of non-black-box (strong) any-simulation-extractability in Appendix A.2.

## 3 Subversion Algebraic Knowledge Assumptions

AGM is a new model FKL18 that one can use to prove the security of cryptographic assumptions, protocols, and primitives. Essentially, in AGM one assumes that each PPT algorithm (including the adversaries) is algebraic in the following sense: if the adversary $\mathcal{A}$ 's input includes $\left[\boldsymbol{x}_{\iota}\right]_{\iota}$ and no other elements from the group $\mathbb{G}_{\iota}$ and $\mathcal{A}$ outputs group elements $\left[\boldsymbol{y}_{\iota}\right]_{\iota}$, then $\mathcal{A}$ knows matrices $\boldsymbol{N}_{\iota}$, such that $\boldsymbol{y}_{\iota}=\boldsymbol{N}_{\iota} \boldsymbol{x}_{\iota}$. While [FKL18] defined AGM by requiring the adversaries in the security proof to output $\left[\boldsymbol{x}_{\iota}\right]_{\iota}$ together with $\boldsymbol{N}_{\iota}$, we find it more convenient to define AGM as a general knowledge assumption.

Let $\mathbb{G}_{\iota}$ be a cyclic group of prime order $p$. A PPT algorithm $\mathcal{A}$ is algebraic [BV98] (in $\left.\mathbb{G}_{\iota}\right)$ if there exists an efficient extractor Ext $\mathcal{A}_{\mathcal{A}}$, such that for any PPT sampleable distribution $\mathcal{D}, \operatorname{Adv}_{\mathbb{G}_{\iota}, \mathcal{D}, \mathcal{A}}^{\mathrm{ak}}(\lambda)=\operatorname{negl}(\lambda)$, where $\operatorname{Adv}_{\mathbb{G}_{\iota}, \mathcal{D}, \mathcal{A}}^{\mathrm{ak}}(\lambda):=$

$$
\operatorname{Pr}\left[[\boldsymbol{x}]_{\iota} \leftarrow \mathcal{D} ; r \leftarrow \leftarrow_{\delta} \operatorname{RND}(\mathcal{A}) ;[\boldsymbol{y}]_{\iota} \leftarrow \mathcal{A}\left([\boldsymbol{x}]_{\iota} ; r\right) ; \boldsymbol{N} \leftarrow \operatorname{Ext}_{\mathcal{A}}\left([\boldsymbol{x}]_{\iota} ; r\right): \boldsymbol{y} \neq \boldsymbol{N} \boldsymbol{x}\right] .
$$

A group $\mathbb{G}_{\iota}$ is algebraic if every PPT algorithm $\mathcal{A}$ that obtains inputs from $\mathbb{G}_{\iota}$ and outputs elements in $\mathbb{G}_{\iota}$ is algebraic.

The restriction that adversaries are algebraic is not valid Bro01SPMS02 in situations where the adversary can create new random group elements by say using elliptic curve hashing [ca09. We model this capability by allowing the adversary to create additional group elements $[\boldsymbol{q}]_{\iota}$ for which she does not know discrete logarithms. We require that $\left[\boldsymbol{q}_{\iota}\right]_{\iota}$ (but not necessarily $\boldsymbol{q}_{\iota}$ ) can be extracted from the adversary, such that $\boldsymbol{y}=\boldsymbol{N} \cdot\binom{\boldsymbol{x}}{\boldsymbol{q}}$. Moreover, $[\boldsymbol{q}]_{\iota}$ must be sampled from a public distribution $\mathcal{D}^{\prime}$. For example, if elliptic-curve hashing is used, one can assume that $[\boldsymbol{q}]_{\iota}$ is close to uniformly random.

We say that a PPT algorithm $\mathcal{A}$ is subversion-algebraic (in $\mathbb{G}_{\iota}$ ) if there exists an efficient extractor $\mathrm{Ext}_{\mathcal{A}}$, s.t. for any PPT sampleable distribution $\mathcal{D}$ and any distribution $\mathcal{D}^{\prime}$ with min-entropy $\omega(\log \lambda)$ (we will analyse the reason for high min-entropy after Lemma 22, $\operatorname{Adv}_{\mathbb{G}_{\iota}, \mathcal{D}, \mathcal{D}^{\prime}, \mathcal{A}}^{\mathrm{sak}}(\lambda):=$

$$
\operatorname{Pr}\left[\begin{array}{l}
{[\boldsymbol{x}]_{\iota} \leftarrow_{\delta} \mathcal{D} ; r \leftarrow_{\delta} \operatorname{RND}(\mathcal{A}) ;[\boldsymbol{y}]_{\iota} \leftarrow_{\delta} \mathcal{A}\left([\boldsymbol{x}]_{\iota} ; r\right) ;} \\
\left(\boldsymbol{N},[\boldsymbol{q}]_{\iota}\right) \leftarrow \operatorname{Ext}_{\mathcal{A}}\left([\boldsymbol{x}]_{\iota} ; r\right):\left(\boldsymbol{y} \neq \boldsymbol{N}\binom{\boldsymbol{x}}{\boldsymbol{q}}\right) \wedge\left([\boldsymbol{q}]_{\iota} \sim \mathcal{D}^{\prime}\right)
\end{array}\right]=\operatorname{negl}(\lambda) .
$$

A group $\mathbb{G}_{\iota}$ is subversion-algebraic if every PPT algorithm $\mathcal{A}$ that obtains inputs from $\mathbb{G}_{\iota}$ and outputs elements in $\mathbb{G}_{\iota}$ is subversion-algebraic. Clearly, a subversionalgebraic adversary is less restricted than an algebraic adversary.

The AGM (resp., Sub-AGM) is essentially the assumption that the given group is algebraic (resp., subversion-algebraic). Let us make this more precise. We formalize the requirement that for fixed $\left(\mathcal{D}, \mathcal{D}^{\prime}\right), \mathcal{A}$ is subversion-algebraic as a concrete $\left(\mathcal{D}, \mathcal{D}^{\prime}, \mathcal{A}\right)$-subversion algebraic knowledge (SAK) assumption in $\mathbb{G}_{\iota}$ stating that $\operatorname{Adv}_{\mathbb{G}_{\iota}, \mathcal{D}, \mathcal{D}^{\prime}, \mathcal{A}}^{\text {sak }}(\lambda)=\operatorname{neg}(\lambda)$. Moreover, a $(\mathcal{D}, \mathcal{A})$-SAK assumption in $\mathbb{G}_{\iota}$ states that $\operatorname{Adv}_{\mathbb{G}_{\iota}, \mathcal{D}, \mathcal{D}^{\prime}, \mathcal{A}}^{\mathrm{sak}}(\lambda)=\operatorname{negl}(\lambda)$ for all distributions $\mathcal{D}^{\prime}$ that have minentropy $\omega(\log \lambda)$. Analogously, the $(\mathcal{D}, \mathcal{A})$-algebraic knowledge $(A K)$ assumption in $\mathbb{G}_{\iota}$ states that $\operatorname{Adv}_{\mathbb{G}_{\iota}, \mathcal{D}, \mathcal{A}}^{\mathrm{ak}}(\lambda)=\operatorname{negl}(\lambda)$.

In $A G M$ for $\mathbb{G}_{\iota}$, one assumes that $(\mathcal{D}, \mathcal{A})$-AK holds in $\mathbb{G}_{\iota}$ for all choices of $(\mathcal{D}, \mathcal{A})$. In Sub-AGM for $\mathbb{G}_{\iota}$, one assumes that $(\mathcal{D}, \mathcal{A})$-SAK holds in $\mathbb{G}_{\iota}$ for all choices of $(\mathcal{D}, \mathcal{A})$. We thus call AGM (resp., Sub-AGM) the $\mathbb{G}_{\iota}-A K$ (resp., $\mathbb{G}_{\iota^{-}}$ $S A K)$ assumption. While proving the security of a concrete protocol, it suffices to rely on the following tautological $\mathcal{D}$-SAK assumption in $\mathbb{G}_{\iota}$ :

Definition 1 ( $\mathcal{D}$-SAK assumption in $\mathbb{G}_{\iota}$ ). For each PPT $\mathcal{A}$ that obtains inputs, distributed according to the distribution $\mathcal{D}$, there exists an extractor that outputs $[\boldsymbol{q}]_{\iota}$ and $\boldsymbol{N}$ such that $[\boldsymbol{q}]_{\iota} \sim \mathcal{D}^{\prime}$ for some distribution $\mathcal{D}^{\prime}$ of high minentropy. More precisely, $\operatorname{Adv}_{\mathbb{G}_{\iota}, \mathcal{D}, \mathcal{D}^{\prime}, \mathcal{A}}^{\text {sak }}(\lambda)=\operatorname{negl}(\lambda)$ for each PPT adversary $\mathcal{A}$ and each distribution $\mathcal{D}^{\prime}$ of min-entropy $\omega(\log \lambda)$.

Let us next demonstrate how SAK assumptions can be used. Consider the $q$-PCDH assumption GJM03|Gro10. Let $\mathcal{D}_{\iota}^{\text {pdl }}=\left\{\left[1, x, x^{1}, \ldots, x^{q}\right]_{\iota}^{\top}: x \leftarrow s \mathbb{Z}_{p}^{*}\right\}$ for uniformly random $x \leftarrow \& \mathbb{Z}_{p}^{*}$. A $q$-PCDH adversary $\mathcal{A}$ is asked, given an input from $\mathcal{D}_{\iota}^{\text {pdl }}$, to output $[y]_{\iota}=\left[x^{q+1}\right]_{\iota}$.

Lemma 1. The $q-P C D H$ assumption is secure under the $q-P D L$ and the $\mathcal{D}_{\iota}^{\text {pdl }}{ }_{-}$ SAK assumptions (all in $\mathbb{G}_{\iota}$ ).

Proof. Here, the $\mathcal{D}_{\iota}^{\text {pdl }}$-SAK assumption in $\mathbb{G}_{\iota}$ states that one can efficiently extract $[\boldsymbol{q}]_{\iota}$ (that comes from some distribution $\mathcal{D}^{\prime}$ of high min-entropy) and integers $N_{i}$ and $N_{i}^{\prime}$ such that $x^{q+1}=\sum_{i=0}^{q} N_{i} x^{i}+\sum N_{i}^{\prime} q_{i}$. It means that either

$$
f(X, \boldsymbol{Q})=X^{q+1}-\sum_{i=0}^{q} N_{i} X^{i}-\sum N_{i}^{\prime} Q_{i}=0
$$

as a polynomial (which is impossible) or $\mathcal{A}$ has returned $x$, such that $(x, \boldsymbol{q})$ is a root of the non-zero polynomial $f(X, \boldsymbol{Q})$. If $\mathcal{A}$ created no new group elements then $f(X)$ is a univariate polynomial and the adversary has broken the $q$-PDL assumption in $\mathbb{G}_{\iota}$. Otherwise, since $\mathcal{D}^{\prime}$ has min-entropy $\Omega(\log \lambda)$ from the viewpoint of $\mathcal{A}$, the probability that $f(x, \boldsymbol{q})=0$ is negligible.

As another example, consider Damgård's original Knowledge-of-Exponent (KE, Dam92]) assumption in $\mathbb{G}_{\iota}$. Here, let $\mathcal{D}_{\iota}^{k e}=\left\{[1, x]_{\iota}^{\top}: x \leftarrow_{s} \mathbb{Z}_{p}^{*}\right\}$. Damgård's KE states that given $[1, x]_{\iota}^{\top} \sim \mathcal{D}_{\iota}^{k e}$, if the adversary outputs $[y, z]_{\iota}$ such that $z=x y$, then there exists an extractor that extracts $y$.

Lemma 2. The KE assumption is secure under the $D L$ and the $\mathcal{D}_{\iota}^{k e}-S A K$ assumptions (all in $\mathbb{G}_{\iota}$ ).

Proof. By the SAK assumption, there exist an extractor that can extract $N$ and $[\boldsymbol{q}]_{1}$ (coming from a distribution of a high min-entropy), such that $\binom{y}{z}=\boldsymbol{N}\left(\begin{array}{l}1 \\ x \\ \boldsymbol{q}\end{array}\right)$, thus $y=Y(x, \boldsymbol{q})$ for $Y(X, \boldsymbol{Q})=N_{11}+N_{12} X+\sum N_{1, k+2} Q_{k}$ and $z=Z(x, \boldsymbol{q})$ for $Z(X, \boldsymbol{Q})=N_{21}+N_{22} X+\sum N_{2, k+2} Q_{k}$. Moreover, we know $z=x y$ and thus for

$$
\begin{aligned}
V(X, \boldsymbol{Q}) & :=Z(X, \boldsymbol{Q})-X Y(X, \boldsymbol{Q}) \\
& =N_{21}+N_{22} X+\sum N_{2, k+2} Q_{k}-X\left(N_{11}+N_{12} X+\sum N_{1, k+2} Q_{k}\right),
\end{aligned}
$$

it holds $V(x, \boldsymbol{q})=0$. If $V(X, \boldsymbol{Q})=0$ as a polynomial then $N_{21}=N_{12}=N_{2, k+2}=$ $N_{1, k+2}=0$ and $N_{22}=N_{11}$. Thus $Y(X, \boldsymbol{Q})=N_{11}$ and $Z(X, \boldsymbol{Q})=N_{22} X=$ $X N_{11}$. Thus, we have extracted $y=N_{11}$ that satisfies $z=y x$. Now, consider the case $V(X, \boldsymbol{Q}) \neq 0$ but $V(x, \boldsymbol{q})=0$. If $\mathcal{A}$ created no new group elements then $V(X)$ is univariate and the adversary has broken the DL assumption (i.e., the 1-PDL assumption) in $\mathbb{G}_{\iota}$. Otherwise, since $\mathcal{D}^{\prime}$ has min-entropy $\Omega(\log \lambda)$ from the viewpoint of $\mathcal{A}$, the probability that $f(x, \boldsymbol{q})=0$ is negligible.

We note that the opposite does not always hold: KE assumption (and its generalizations) cannot be used to extract unless each input group element $[z]_{1}$ is accompanied with a "knowledge" input $[x z]_{1}$ for random $x$.

Let us now analyze the need for high min-entropy. Following Bro01SPMS02, Bellare et al. BFS16ABLZ17 proved subversion-security in the subversion generic bilinear group model (Sub-GBGM, also known as GBGM with elliptic curve hashing) where the adversary can create random group elements $\left[\boldsymbol{q}_{\iota}\right]_{\iota}$ that are interpreted as new indeterminates $\boldsymbol{Q}_{\iota}$ in the security proof. Our approach will be more precise. Motivated by the upcoming security proofs (e.g., see the proof of Theorem 11), we require that $\mathcal{D}^{\prime}$ has min-entropy

$$
H_{\infty}\left(\mathcal{D}^{\prime}\right):=-\log _{2} \max _{\boldsymbol{y}} \operatorname{Pr}\left[\boldsymbol{q} \leftarrow_{\delta} \mathcal{D}^{\prime}: \boldsymbol{q}=\boldsymbol{y}\right]=\omega(\log \lambda)
$$

Really, we will need that for any $\boldsymbol{x}$, a random $\boldsymbol{q}$ is a root of a "verification polynomial" $V^{*}(\boldsymbol{X}, \boldsymbol{Q})$ with negligible probability. We assume that group elements created in $\mathbb{G}_{1}$ and $\mathbb{G}_{2}$ are independent. (See BFS16ABLZ17] for discussion.) Thus, $V^{*}$ has degree one in any indeterminate $Q_{\iota k}$. Thus, it follows from the Schwartz-Zippel lemma Zip79Sch80 that

$$
\operatorname{Pr}\left[V^{*}\left(x, \boldsymbol{q}_{1}, \boldsymbol{q}_{2}\right)=0\right] \leq 2^{-H_{\infty}\left(\mathcal{D}^{\prime}\right)}=2^{-\omega(\log \lambda)}=\lambda^{-\omega(1)}
$$

is negligible $\int_{4}^{4}$ There exist simpler versions of elliptic curve hashing (so called encodings, $\overline{I c a 09}\left(\overline{\mathrm{BCI}^{+} 10}\right)$ where the output is assumed to have high-entropy but is not close to uniform; importantly, such versions suffice for us.

Moreover, the assumption of high min-entropy is quite natural. Really, if $q_{\iota k}$ is equal to some $y_{\iota k}$ with a non-negligible probability then a non-uniform

[^0]adversary that has $y_{\iota k}$ as an advise can compute the discrete logarithm $q_{\iota k}$ with a non-negligible probability. In such a case, $q_{\iota k}$ can be considered as an element with known discrete logarithm.

Importantly, when proving the security under (S)AK assumptions, the adversary is allowed to make use of the group presentation as long as this does not contradict the concrete knowledge assumption. This is important in the tagbased setting where the adversary can choose her own tags (integers).

Finally, in the bilinear-group setting we make both $\mathcal{D}_{1}$-SAK (in $\mathbb{G}_{1}$ ) and $\mathcal{D}_{2}$-SAK (in $\mathbb{G}_{2}$ ) assumptions, with $\mathcal{D}_{1}$ and $\mathcal{D}_{2}$ being possibly correlated (e.g., the input could contain both $[x]_{1}$ and $[x]_{2}$ for random $x$ ). In this case, we say that a PPT algorithm $\mathcal{A}$ is subversion-algebraic (in p ) if there exists an efficient extractor $\mathrm{Ext}_{\mathcal{A}}$, s.t. for any PPT sampleable distribution $\mathcal{D}$ and any distribution $\mathcal{D}^{\prime}$ with min-entropy $\omega(\log \lambda), \operatorname{Adv}_{\mathrm{p}, \mathcal{D}, \mathcal{D}^{\prime}, \mathcal{A}}^{\mathrm{sak}}(\lambda):=$
$\operatorname{Pr}\left[\begin{array}{l}\mathrm{x}=\left(\left[\boldsymbol{x}_{1}\right]_{1},\left[\boldsymbol{x}_{2}\right]_{2}\right) \leftarrow \mathrm{s} \mathcal{D} ; r \leftarrow \mathrm{RND}(\mathcal{A}) ;\left(\left[\boldsymbol{y}_{1}\right]_{1},\left[\boldsymbol{y}_{2}\right]_{2}\right) \leftarrow \& \mathcal{A}(\mathrm{x} ; r) ; \\ \left(\boldsymbol{N}_{1}, \boldsymbol{N}_{2},\left[\boldsymbol{q}_{1}\right]_{1},\left[\boldsymbol{q}_{2}\right]_{2}\right) \leftarrow \operatorname{Ext} \mathcal{A}_{\mathcal{A}}(\mathrm{x} ; r): \\ \left(\boldsymbol{y}_{1} \neq \boldsymbol{N}_{1}\binom{\boldsymbol{x}_{1}}{\boldsymbol{q}_{1}} \vee \boldsymbol{y}_{2} \neq \boldsymbol{N}_{2}\binom{\boldsymbol{x}_{2}}{\boldsymbol{q}_{2}}\right) \wedge\left(\left(\left[\boldsymbol{q}_{1}\right]_{1},\left[\boldsymbol{q}_{2}\right]_{2}\right) \sim \mathcal{D}^{\prime}\right)\end{array}\right]=\operatorname{negl}(\lambda)$.
We define the $\mathcal{D}$-AK assumption in p analogously.

## 4 Knowledge-Sound SNARK for QAP

In this section, we will describe new SNARKs $\mathrm{S}_{\text {qap }}$ (SNARK for QAP) and $S_{\text {qap }}^{\text {se }}(\underline{S N A R K}$ for QAP, $\underline{\mathrm{SE})}$ for QAP. The template follows two objectives: (i) simple soundness proof under an SAK assumption, and (ii) efficiency. In fact, $\mathrm{S}_{\text {qap }}$ is very similar to Groth's SNARK from EUROCRYPT 2016 Gro16 with the main difference being the use of only two trapdoors instead of five. The second difference is an alternative, much simpler, knowledge-soundness proof in the case of asymmetric pairings; Groth on the other hand provided a very complex knowledge-soundness proof that is valid for both asymmetric and symmetric pairings. The new tag-based SASE SNARK $\mathrm{S}_{\text {qap }}^{\text {se }}$ is novel and we are not aware of any prior art tag-based SNARKs at all.

Let $u(X)=\sum_{j=1}^{m} a_{j} u_{j}(X), v(X)=\sum_{j=1}^{m} a_{j} v_{j}(X)$, and $w(X)=$ $\sum_{j=1}^{m} a_{j} w_{j}(X)$ as in Section 2 Recall from Eq. 22 that for $\chi(X)=u(X) v(X)-$ $w(X)-h(X) \ell(X)$, the key equation of QAP states that $\chi(X)=0$. That is, $h(X):=(u(X) v(X)-w(X)) / \ell(X)$ is a polynomial iff the prover is honest.

The argument in the new template consists of three elements, $\pi=$ ( $[\mathrm{a}, \mathrm{c}]_{1},[\mathrm{~b}]_{2}$ ), where $\mathrm{a}=A(x, y), \mathrm{b}=B(x, y)$, and $\mathrm{c}=C(x, y)$ for well-defined polynomials $A(X, Y), B(X, Y)$, and $C(X, Y)$. Intuitively, [a] $]_{1}$ is a succinct commitment to $u(X),[\mathrm{b}]_{2}$ is a succinct commitment to $v(X)$, and $[\mathrm{c}]_{1}$ is the "actual" argument that additionally commits to $w(X)$. More precisely, let $\alpha, \beta, \gamma$, and $\delta$ be integers chosen later. Then

$$
\begin{equation*}
A(X, Y)=r_{a} Y^{\alpha}+u(X) Y^{\beta} \quad, \quad B(X, Y)=r_{b} Y^{\alpha}+v(X) Y^{\beta} \tag{3}
\end{equation*}
$$

We now define

$$
\begin{align*}
& C(X, Y)=\left(A(X, Y)+Y^{\gamma}\right)\left(B(X, Y)+Y^{\delta}\right)-Y^{\gamma+\delta} \\
&= A(X, Y) B(X, Y)+B(X, Y) Y^{\gamma}+A(X, Y) Y^{\delta} \\
&= u(X) Y^{\beta+\delta}+v(X) Y^{\beta+\gamma}+w(X) Y^{2 \beta}+(u(X) v(X)-w(X)) Y^{2 \beta}+ \\
& r_{b}\left(r_{a} Y^{\alpha}+u(X) Y^{\beta}+Y^{\gamma}\right) Y^{\alpha}+r_{a}\left(v(X) Y^{\beta}+Y^{\delta}\right) Y^{\alpha}  \tag{4}\\
&= \sum_{j=1}^{m} a_{j}\left(u_{j}(X) Y^{\beta+\delta}+v_{j}(X) Y^{\beta+\gamma}+w_{j}(X) Y^{2 \beta}\right)+ \\
&(u(X) v(X)-w(X)) Y^{2 \beta}+r_{b}\left(A(X, Y)+Y^{\gamma}\right) Y^{\alpha}+ \\
& r_{a}\left(v(X) Y^{\beta}+Y^{\delta}\right) Y^{\alpha} .
\end{align*}
$$

Since the SNARK also has a public input $\left(a_{j}\right)_{j=1}^{m_{0}}$, we define two polynomials $C_{s}(X, Y)$ and $C_{p}(X, Y)$, so that for another integer $\eta$,

$$
C(X, Y)=C_{p}(X, Y) Y^{\eta}+C_{s}(X, Y) Y^{\alpha}
$$

where $C_{p}(X, Y)$ depends only on $a_{j}$ for $j \leq m_{0}, C_{s}(X, Y)$ depends only on $a_{j}$ for $j>m_{0}$, and $C_{p}(X, Y)$ only has $m_{0}$ addends (to minimize the computation, performed by the verifier):

$$
\begin{align*}
& C_{p}(X, Y)=\sum_{j=1}^{m_{0}} a_{j}\left(u_{j}(X) Y^{\beta-\eta+\delta}+v_{j}(X) Y^{\beta-\eta+\gamma}+w_{j}(X) Y^{2 \beta-\eta}\right) \\
& C_{s}(X, Y)=\sum_{j=m_{0}+1}^{m} a_{j}\left(u_{j}(X) Y^{\beta-\alpha+\delta}+v_{j}(X) Y^{\beta-\alpha+\gamma}+w_{j}(X) Y^{2 \beta-\alpha}\right)+  \tag{5}\\
& \quad(u(X) v(X)-w(X)) Y^{2 \beta-\alpha}+r_{b}\left(A(X, Y)+Y^{\gamma}\right)+r_{a} v(X) Y^{\beta}+r_{a} Y^{\delta} .
\end{align*}
$$

Here, we use the multiplicand $Y^{\alpha}$ for efficiency reasons, since $C(X, Y)$ has an addend $r_{a} A(X, Y) Y^{\alpha}$.

Hence, the argument consists of three elements, $\pi=\left(\left[\mathrm{a}, \mathrm{c}_{s}\right]_{1},[\mathrm{~b}]_{2}\right)$, where $\mathrm{c}_{s}=C_{s}(x, y)$ and the verifier recomputes $[C(x, y)]_{T}=\left[\mathrm{c}_{p}\right]_{1} \bullet\left[y^{\eta}\right]_{2}+\left[\mathrm{c}_{s}\right]_{1} \bullet\left[y^{\alpha}\right]_{2}$. Essentially, the verifier of the new SNARK checks that $[\mathrm{c}(x, y)]_{T}$ is computed correctly by checking that $[\mathrm{c}]_{T}=\left([\mathrm{a}]_{1}+\left[y^{\gamma}\right]_{1}\right) \bullet\left([\mathrm{b}]_{2}+\left[y^{\delta}\right]_{2}\right)-\left[y^{\gamma+\delta}\right]_{T}$.

We prove knowledge-soundness based on a PDL and a SAK assumption. Recall that the adversary can create a number of new random group elements $\left[\boldsymbol{q}_{1}\right]_{1}$ and $\left[\boldsymbol{q}_{2}\right]_{2}$. Let $\boldsymbol{Q}_{\iota}$ be the vector of corresponding formal indeterminates in $\mathbb{G}_{\iota}$ for $\iota \in\{1,2\}$. Let $\boldsymbol{Q}=\left(\boldsymbol{Q}_{1}, \boldsymbol{Q}_{2}\right)$ and let $\boldsymbol{X}=(X, \boldsymbol{Q}, Y)$ be the vector of all indeterminates. Then, the verification guarantees that $V(\boldsymbol{x})=0$, where

$$
\begin{equation*}
V(\boldsymbol{X})=\left(A(\boldsymbol{X})+Y^{\gamma}\right)\left(B(\boldsymbol{X})+Y^{\delta}\right)-Y^{\gamma+\delta}-C_{p}(\boldsymbol{X}) Y^{\eta}-C_{s}(\boldsymbol{X}) Y^{\alpha} \tag{6}
\end{equation*}
$$

and $A(\boldsymbol{X}), B(\boldsymbol{X})$, and $C_{s}(\boldsymbol{X})$ are potentially maliciously computed polynomials that may depend on the indeterminates $\boldsymbol{Q}$.

By the SAK assumption, all coefficients of $V$ are known. Assume first that $V(\boldsymbol{X})=0$ is a zero polynomial and let $\boldsymbol{X}^{*}=(X, \boldsymbol{Q})$. Writing $V(\boldsymbol{X})=$ $\sum_{i} V_{i}\left(\boldsymbol{X}^{*}\right) Y^{i}$, we get that each $V_{i}\left(\boldsymbol{X}^{*}\right)=0$. To simplify the knowledgesoundness proof, we construct the SNARK so that for some small set Crit,
$\chi(X)=0$ follows from $V_{i}\left(\boldsymbol{X}^{*}\right)=0$ for $i \in$ Crit. Second, if $V(\boldsymbol{X}) \neq 0$ as a polynomial but the verification succeeds, then $V(\boldsymbol{x})=0$ and by a modification of the same strategy of Lemmas 1 and 2, one can break the PDL assumption.

To formalize this discussion, in the malicious case $A(\boldsymbol{X}), B(\boldsymbol{X})$, and $C_{s}(\boldsymbol{X})$ can be any polynomials in the span of polynomials represented in the CRS and of monomials consisting of the new indeterminates $Q_{c k}$ in groups $\mathbb{G}_{1}, \mathbb{G}_{2}$, and $\mathbb{G}_{1}$, respectively. More precisely, any maliciously computed polynomials $\mathrm{crs}_{1}(a, \boldsymbol{X})$ and $\operatorname{crs}_{2}(b, \boldsymbol{X})$, where $a$ and $b$ are symbolic ("string") variables, that represent group elements in $\mathbb{G}_{1}$ and $\mathbb{G}_{2}$ respectively, have to have the following shape. This shape follows from the description of crs in Fig. 2, which in its turn follows from the elements that either the honest prover or the honest verifier have to be able to compute during the argument. It also takes into account indeterminates $Q_{\iota k}$ that correspond to new group elements $\left[q_{\iota k}\right]_{\iota}$.

$$
\begin{align*}
& \operatorname{crs}_{1}(a, \boldsymbol{X})=\sum_{j=1}^{m_{0}} a_{j}^{*}\left(u_{j}(X) Y^{\beta-\eta+\delta}+v_{j}(X) Y^{\beta-\eta+\gamma}+w_{j}(X) Y^{2 \beta-\eta}\right)+ \\
& \sum_{i=m_{0}+1}^{m} a_{i}^{*}\left(u_{i}(X) Y^{\beta-\alpha+\delta}+v_{i}(X) Y^{\beta-\alpha+\gamma}+w_{i}(X) Y^{2 \beta-\alpha}\right)+  \tag{7}\\
& h_{a}(X) \ell(X) Y^{2 \beta-\alpha}+r_{a} Y^{\alpha}+u_{a}(X) Y^{\beta}+a_{\gamma} Y^{\gamma}+a_{\delta} Y^{\delta}+\sum_{k} q_{a k} Q_{1 k} \\
& \operatorname{crs}_{2}(b, \boldsymbol{X})=r_{b} Y^{\alpha}+v_{b}(X) Y^{\beta}+b_{\delta} Y^{\delta}+b_{\eta} Y^{\eta}+\sum_{k} b_{q k} Q_{2 k}
\end{align*}
$$

where say $a_{j}^{*} \in \mathbb{Z}_{p}, u_{a}(X) \in \mathbb{Z}_{p}[X]$ is a degree- $\leq(n-1)$ polynomial, and $h_{a}(X) \in \mathbb{Z}_{p}[X]$ is a degree- $\leq(n-2)$ polynomial. Then, $A(\boldsymbol{X})=c r s_{1}(a, \boldsymbol{X})=$ $\cdots+r_{a} Y^{\alpha}+u_{a}(X) Y^{\beta}+\cdots, C_{s}(\boldsymbol{X})=\operatorname{crs}_{1}(c, \boldsymbol{X})=\cdots+r_{c} Y^{\alpha}+u_{c}(X) Y^{\beta}+\cdots$, and $B(\boldsymbol{X})=c r s_{2}(b, \boldsymbol{X})=r_{b} Y^{\alpha}+\cdots$. Thus, $V(\boldsymbol{X})$ is defined as in Eq. (6) but with polynomials $A(\boldsymbol{X}), B(\boldsymbol{X})$, and $C_{s}(\boldsymbol{X})$ as defined in Eq. (7).

Second, for the described proof idea to go through, we need $2 \beta$ to be different from all other exponents in maliciously computed $V^{*}(\boldsymbol{X})$. Moreover, the prover is honest iff $\chi(X)=0$ iff $u(X) v(X)-w(X)=h(X) \ell(X)$ for some polynomial $h(X)$ iff the coefficient of $Y^{2 \beta}$ in $C(\boldsymbol{X})$ is divisible by $\ell(X)$. In addition, $C_{s}(\boldsymbol{X})$ has addends $u_{j}(X) Y^{\beta-\alpha+\delta}, v_{j}(X) Y^{\beta-\alpha+\gamma}$, and $w_{j}(X) Y^{2 \beta-\alpha}$; thus their sum can be written as $\sum_{j=1}^{m} a_{j} f_{j}(X, Y)$ for known polynomials $f_{j}(X, Y)$, as above. This and the shape of the coefficient of $Y^{2 \beta-\alpha}$ are the main reasons why we defined $C(X, Y)$ as in Eq. (4). Let $R=\left\{i: V_{i}\left(\boldsymbol{X}^{*}\right) \neq 0\right\}$, and

$$
\text { Crit }=\{2 \beta, \beta+\gamma, \beta+\delta, \gamma+\delta, \gamma+\eta, 2 \delta\}
$$

and $\overline{\text { Crit }}=R \backslash \overline{\text { Crit }}$ be the complement of Crit. Let $\boldsymbol{\Delta}=(\alpha, \beta, \gamma, \eta, \delta)$. To obtain knowledge-soundness, we will need to choose the values in $\Delta$ so that Crit consists of mutually different integers $(\mid$ Crit $\mid=6)$ and Crit $\cap \overline{\text { Crit }}=\emptyset$. The reason of this definition of Crit will become clear from the proof of Theorem 1 and from the following observation. Let $h(X):=h_{c}(X)-r_{b} h_{a}(X)$. Let

$$
\tilde{a}_{j}= \begin{cases}a_{j}-b_{\eta} a_{j}^{*}, & j \leq m_{0} \\ c_{j}^{*}-r_{b} a_{j}^{*}, & j>m_{0}\end{cases}
$$

Denote $u(X)=\sum_{j=1}^{m} \tilde{a}_{j} u_{j}(X), v(X)=\sum_{j=1}^{m} \tilde{a}_{j} v_{j}(X)$, and $w(X)=$ $\sum_{j=1}^{m} \tilde{a}_{j} w_{j}(X)$. In this case, the "critical" coefficients $V_{i}\left(\boldsymbol{X}^{*}\right), i \in$ Crit, of $V(\boldsymbol{X})$

| $Y^{i}$ | Coeff. $V_{i}\left(\boldsymbol{X}^{*}\right)($ KS and SASE $)$ | $V_{i}^{+}\left(\boldsymbol{X}^{*}\right)$ (SASE only) |
| :--- | :--- | :--- |
| $Y^{2 \beta}$ | $u_{a}(X) v_{b}(X)-w(X)-h(X) \ell(X)$ | $\sum_{k}\left(s_{c 2 k}-r_{b} s_{a 2 k}\right) \sum_{j} \sigma_{k j} w_{j}(X)$ |
| $Y^{\beta+\gamma}\left(a_{\gamma}+1\right) v_{b}(X)-v(X)$ | $\sum_{k}\left(s_{c 2 k}-r_{b} s_{a 2 k}\right) \sum_{j} \sigma_{k j} v_{j}(X)$ |  |
| $Y^{\beta+\delta}\left(b_{\delta}+1\right) u_{a}(X)-u(X)+a_{\delta} v_{b}(X)$ | $\sum_{k}\left(s_{c 2 k}-r_{b} s_{a 2 k}\right) \sum_{j} \sigma_{k j} u_{j}(X)$ |  |
| $Y^{\gamma+\delta} b_{\delta}+a_{\gamma}\left(b_{\delta}+1\right)$ |  |  |
| $Y^{\gamma+\eta}\left(a_{\gamma}+1\right) b_{\eta}$ |  |  |
| $Y^{2 \delta}\left(b_{\delta}+1\right) a_{\delta}$ | $r_{b} s_{a 2 k}-s_{c 2 k}+\left(a_{\gamma}+1\right) s_{b k}$ |  |
| $Y^{\gamma} E_{k}$ |  |  |

Fig. 1. Critical coefficients in $\mathrm{S}_{\text {qap }}$ (left) and addends to the same coefficients in the SASE case (right). The coefficient of $Y^{\gamma} E_{k}$ is 0 in the case of $\mathrm{S}_{\text {qap }}$.
are depicted in Fig. 1 . As argued in the the proof of Theorem 1 , from $V_{i}\left(\boldsymbol{X}^{*}\right)=0$ for $i \in$ Crit it follows that $\chi(X)=0$.

We are now ready to describe the SNARK $\mathrm{S}_{\text {qap }}$, see Fig. 2, and prove its security. (Note that tags $\tau$ are only used in the SASE version.) Like Gro16 but unlike say [GGPR13], $\mathrm{S}_{\text {qap }}$ guarantees that $u(X), v(X)$, and $w(X)$ use the same witness $\boldsymbol{a}$ without having to use a strong QAP [GGPR13].

Before stating the following theorem, we need to specify the $\mathcal{D}$-SAK assumption. More precisely, we need to define $\mathcal{D}$, since $\mathbb{G}_{\iota}$ is fixed by the protocol. Here and in the rest of the paper, $\mathcal{D}_{\mathbf{R}}^{\text {crs }}{ }^{\text {aux }}{ }_{\mathbf{R}}(\Psi)$ is the distribution of honestly generated CRS of SNARK $\Psi=\left(\mathrm{K}_{\mathrm{crs}}, \mathrm{P}, \mathrm{V}, \operatorname{Sim}\right)$ for the concrete QAP instance $\mathbf{R}=$ Inst $_{\text {qap }}$ and for $\operatorname{aux}_{\mathbf{R}}$. That is,

$$
\mathcal{D}_{\mathbf{R}, \mathrm{aux}_{\mathbf{R}}}^{\mathrm{crs}}(\Psi)=\left\{\mathrm{crs}:(\mathrm{crs}, \mathrm{td}) \leftarrow \mathrm{K}_{\mathrm{crs}}\left(\mathbf{R}, \mathrm{aux}_{\mathbf{R}}\right)\right\}
$$

Theorem 1. Let $\mathbf{R}=\operatorname{Inst}_{\text {qap }}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}, v_{j}, w_{j}\right\}_{j=0}^{m}\right)$ be a $Q A P$ instance. Let $\mathrm{S}_{\text {qap }}$ be the SNARK in Fig. 2 .
(1) Assume $\boldsymbol{\Delta}$ satisfies Crit $\cap \overline{\text { Crit }}=\emptyset$. Then, $\mathrm{S}_{\text {qap }}$ is knowledge-sound under the ( $2 n-1, n-1$ )-PDL and $\mathcal{D}_{\mathbf{R}, \text { aux }}^{\text {crs }}\left(\mathrm{S}_{\text {qap }}\right)$-SAK assumptions.
(2) $\mathrm{S}_{\text {qap }}$ is perfectly zero-knowledge.

We emphasize that the following knowledge-soundness proof depends minimally on the concrete SNARK: the only SNARK-dependent part is the Step 1. The rest of the knowledge-soundness proof can basically be copied to the knowledge-soundness proofs of all following SNARKs.

Proof. (1: knowledge-soundness) In all following knowledge-soundness and SASE proofs, we will use the following template. We use the $\mathcal{D}_{\mathbf{R}, \text { au× }}^{\text {crs }}\left(\mathrm{S}_{\text {qap }}\right)$ SAK assumption to extract all coefficients of $V(\boldsymbol{X})$. Since the verifier accepts, $V(\boldsymbol{x})=0$ where $\boldsymbol{x}$ is the vector of actual trapdoors. We will move everything from group elements to indeterminates, and we argue that if the verification polynomial $V(\boldsymbol{X})$ is a zero polynomial $(V(\boldsymbol{X})=0)$ then the prover did not cheat. After that, we use the PDL assumption to derive a contradiction from $V(\boldsymbol{X}) \neq 0$ but $V(\boldsymbol{x})=0$; we also argue that due to the high min-entropy of the distribution $\mathcal{D}^{\prime}$ of $\left(\left[\boldsymbol{q}_{1}\right]_{1},\left[\boldsymbol{q}_{2}\right]_{2}\right)$, creating random group elements does not benefit $\mathcal{A}$. These
$\mathrm{K}_{\text {crs }}\left(\mathbf{R}\right.$, aux $\left._{\mathbf{R}}\right):$ Sample $x, y, z \leftarrow \Phi \mathbb{Z}_{p}^{*}$, let $\mathrm{td} \leftarrow(x, y, z)$. Let

$$
\begin{aligned}
& \operatorname{crsp}_{\mathrm{P}} \leftarrow\left(\begin{array}{l}
{\left[\left\{u_{j}(x) y^{\beta-\alpha+\delta}+v_{j}(x) y^{\beta-\alpha+\gamma}+w_{j}(x) y^{2 \beta-\alpha}\right\}_{j=m_{0}+1}^{m}\right]_{1}} \\
{\left[y^{\alpha},\left\{x^{j} y^{\beta}\right\}_{j=0}^{n-1},\left\{x^{i} \ell(x) y^{2 \beta-\alpha}\right\}_{j=0}^{n-2}, y^{\gamma}, y^{\delta}, y^{\alpha} z,\left\{x^{j} y^{\beta} z\right\}_{j=0}^{n-1}\right]_{1},} \\
{\left[y^{\alpha},\left\{x^{j} y^{\beta}\right\}_{j=0}^{n-1}\right]_{2}}
\end{array}\right) ; \\

Fig. 2. The new SNARKs $\mathrm{S}_{\text {qap }}$ (without highlighted entries) and $\mathrm{S}_{\text {qap }}^{\text {se }}$ (with highlighted entries). Moreover, $\mathbf{S}_{\text {qsp }}$ is exactly like $\mathbf{S}_{\text {qap }}$ and $\mathbf{S}_{\text {q5p }}^{\text {se }}$ is exactly like $\mathbf{S}_{\text {qap }}^{\text {se }}$, except $w_{j}(X)=0$
two steps together guarantee that the SNARK is knowledge-sound/SASE: if the verifier accepted and the PDL assumption holds, then $V(\boldsymbol{X})=0$ as a polynomial and thus the prover did not cheat.

Let $\mathcal{A}$ be a knowledge-soundness adversary that, given ( $\mathbf{R}, \operatorname{aux}_{\mathbf{R}}, \mathrm{crs} ; r$ ) as an input succeeds in outputting $(\mathrm{x}, \pi)$ such that $\mathrm{x} \notin \mathcal{L}$ but V accepts. Denote crs $=\left(\left[\boldsymbol{\Gamma}_{1}\right]_{1},\left[\boldsymbol{\Gamma}_{2}\right]_{2}\right) .\left(\left[y^{\gamma+\delta}\right]_{T}\right.$ is only included to the CRS as an optimization and has no influence on the security.) Denote $\mathcal{D}=\mathcal{D}_{\mathbf{R}, \mathrm{aux}_{\mathbf{R}}}^{\text {crs }}\left(\mathrm{S}_{\text {qap }}\right)$. By the SAK assumption, there exists an extractor $\mathrm{Ext}_{\mathcal{A}}$ that on the same inputs, with probability $1-\operatorname{Adv}_{\mathrm{p}, \mathcal{D}, \mathcal{D}^{\prime}, \mathcal{A}}^{\text {sak }}(\lambda)=1-\operatorname{negl}(\lambda)$, returns $\boldsymbol{N}_{1}, \boldsymbol{N}_{2},\left[\boldsymbol{q}_{1}\right]_{1}$ and $\left[\boldsymbol{q}_{2}\right]_{1}$, such
that $\left(\mathrm{a}, \boldsymbol{c}_{s}\right)^{\top}=\boldsymbol{N}_{1}\binom{\boldsymbol{\Gamma}_{1}}{\boldsymbol{q}_{1}}$ and $\mathrm{b}=\boldsymbol{N}_{2}\binom{\boldsymbol{\Gamma}_{2}}{\boldsymbol{q}_{2}}$. We abort if the extractor does not succeed. As above, write $\mathrm{a}=A(\boldsymbol{x}), \mathrm{c}=C(\boldsymbol{x})$, and $\mathrm{b}=B(\boldsymbol{x})$. Taking into account that elements of $\boldsymbol{\Gamma}_{\iota}$ are known polynomials of $x$ and $y$, we can efficiently the coefficients of the polynomials $A(\boldsymbol{X}), C(\boldsymbol{X})$, and $B(\boldsymbol{X})$ from $\boldsymbol{N}_{1}$ and $\boldsymbol{N}_{2}$.

Step 1. Assume first that $V(\boldsymbol{X})=0$ and thus $V_{i}\left(\boldsymbol{X}^{*}\right)=0$ for $i \in$ Crit. Consider Fig. 1 . Since $V_{\gamma+\delta}\left(\boldsymbol{X}^{*}\right)=b_{\delta}+a_{\gamma}\left(b_{\delta}+1\right)=0$, we have $a_{\gamma}=-b_{\delta} /\left(b_{\delta}+1\right)$. Thus, $a_{\gamma}, b_{\delta} \neq-1$ and $\left(a_{\gamma}+1\right)\left(b_{\delta}+1\right)=1$. Moreover, $V_{\eta+\gamma}\left(\boldsymbol{X}^{*}\right)=\left(a_{\gamma}+1\right) b_{\eta}=0$ and thus $b_{\eta}=0$. Next, $V_{2 \delta}\left(\boldsymbol{X}^{*}\right)=a_{\delta}=0$. Thus, $\tilde{a}_{j}=a_{j}$ for $j \leq m_{0}$. Finally, $\left(b_{\delta}+1\right) u_{a}(X)=u(X),\left(a_{\gamma}+1\right) v_{b}(X)=v(X)$, and $\chi(X)=u(X) v(X)-w(X)-$ $\ell(X) h(X)=0$, thus the prover did not cheat.

Step 2. Assume that $V(\boldsymbol{X}) \neq 0$ but $V(\boldsymbol{x})=0$, then the extractor has produced a root of the non-zero multivariate polynomial $V(\boldsymbol{X})$. We will first consider the case when the adversary did not create any new group elements in $\mathbb{G}_{1}$ and $\mathbb{G}_{2}$, i.e., we are working in the "non-subversion" case. After that, we show how to reduce the subversion case to the non-subversion case.

In the non-subversion case, assume that the SAK assumption holds and that $\mathcal{A}$ is a knowledge-soundness adversary that succeeds with probability $\varepsilon_{\text {snd }}:=$ $\operatorname{Adv}_{\mathcal{R}, \mathcal{A}}^{\mathrm{snd}}(\lambda)$ where $\varepsilon_{\text {snd }}>\varepsilon_{\text {sak }}:=\operatorname{Adv}_{\mathrm{p}, \mathcal{D}, \mathcal{D}^{\prime}, \mathcal{A}}^{\mathrm{sak}}(\lambda)$. Note that due to the SAK assumption, $\varepsilon_{s a k}=\operatorname{negl}(\lambda)$. We construct the following PDL adversary $\mathcal{B}$. The challenger $\mathcal{C}$ samples $x \leftarrow_{\&} \mathbb{Z}_{p}^{*}$ and gives $\mathrm{x}=\left(\left[1, x, \ldots, x^{2 n-1}\right]_{1},\left[1, x, \ldots, x^{n-1}\right]_{2}\right)$ as an input to $\mathcal{B}$. $\mathcal{B}$ samples $y \leftarrow \mathbb{Z}_{p}^{*}$, and uses it together with $\left(\mathbf{R}\right.$, aux $\left.\mathbf{x}_{\mathbf{R}}\right)$ and $\times$ to create correctly distributed crs. $\mathcal{B}$ plays the challenger in the knowledgesoundness game with $\mathcal{A}$ : after sending crs and $r \leftarrow \operatorname{RND}(\mathcal{A})$ to $\mathcal{A}, \mathcal{B}$ obtains a purported proof $\left(\left[\mathrm{a}, \mathrm{c}_{s}\right]_{1},[\mathrm{~b}]_{2}\right)$ from $\mathcal{A}$. $\mathcal{B}$ runs the extractor Ext $\mathcal{A}_{\mathcal{A}}$, guaranteed by the SAK assumption to succeed with probability $1-\operatorname{negl}(\lambda)$, to obtain matrices $\boldsymbol{N}_{\iota}$ and $\left[\boldsymbol{q}_{\iota}\right]_{\iota}$ (the latter is empty in the non-subversion case). From $\boldsymbol{N}_{\iota}$, she computes the coefficients of various polynomials like $A(X, Y), B(X, Y), C_{s}(X, Y)$, and $V(X, Y)$. Now, $[\mathrm{a}]_{1}=[A(x, y)]_{1},\left[\mathrm{c}_{s}\right]_{1}=\left[C_{s}(x, y)\right]_{1}$, and $[\mathrm{b}]_{2}=[B(x, y)]_{2}$. Since the verifier accepts, $V(x, y)=0$; however, $V(X, Y) \neq 0$ as a polynomial. For the fixed value of $y \in \mathbb{Z}_{p}^{*}$, let $V^{*}(X):=V(X, y)$. Finally, $\mathcal{B}$ does the following:

1. Use an efficient polynomial factorization algorithm to obtain up to $2 n-1$ roots $x_{i}$ of $V^{*}(X)$.
2. Return the root $x_{i}$ that satisfies $\left[x_{i} y^{\beta}\right]_{1}=\left[x y^{\beta}\right]_{1}$.

Clearly, $\mathcal{B}$ has broken the $(2 n-1, n-1)$-PDL assumption with probability $\varepsilon_{p d l}=$ $\operatorname{Adv}_{2 n-1, n-1, \text { Pgen }, \mathcal{B}}^{\mathrm{pdl}}(\lambda) \geq \varepsilon_{\text {snd }}-\varepsilon_{\text {sak }}$. Thus,

$$
\varepsilon_{\text {snd }} \leq \operatorname{Adv}_{2 n-1, n-1, \operatorname{Pgen}, \mathcal{B}}^{\mathrm{pdl}}(\lambda)+\operatorname{Adv}_{\mathrm{p}, \mathcal{D}, \mathcal{D}^{\prime}, \mathcal{A}}^{\mathrm{sak}}(\lambda)
$$

Moreover, $\mathcal{B}$ 's running time is dominated by the running time of $\mathcal{A}$ and the time to perform polynomial factorization.

Consider now the subversion case when $\mathcal{A}$ has created at least one random group element $q_{\iota k}$. We will rely on the fact that the new group elements $q_{\iota k}$ are added additively to a polynomial of $x$ in both groups, and moreover, the elements
in $\mathbb{G}_{1}$ and $\mathbb{G}_{2}$ are independent. Then, $V^{*}(X, \boldsymbol{Q})$ is a degree- 1 polynomial in any indeterminate $Q_{\iota k}$. Thus, by the Schwartz-Zippel lemma and since $H_{\infty}\left(\mathcal{D}^{\prime}\right)=$ $\omega(\log \lambda)$, for any $x$, the probability that $V^{*}(x, \boldsymbol{q})=0$ is negligible. Hence, the probability that an adversary, who created at least one (high min-entropy) group element $\left[q_{\iota k}\right]_{1}$, can make the verifier accept is negligible.
(2: zero-knowledge) To see that $\operatorname{Sim}$ makes the verifier accept, note that $\left(\mathrm{a}+y^{\gamma}\right)\left(\mathrm{b}+y^{\delta}\right)-\mathrm{c}_{s} y^{\alpha}-\mathrm{c}_{p} y^{\eta}-y^{\gamma+\delta}=d e+d y^{\delta}+e y^{\gamma}-\mathrm{c}_{p} y^{\eta}-\left(d e+d y^{\delta}+\right.$ $\left.e y^{\gamma}-\mathrm{c}_{p} y^{\eta}\right)=0$. Sim's output comes from the correct distribution since a and b are individually uniform in $\mathbb{Z}_{p}$, and c is chosen so that V accepts.

In Appendix B, we observe that if the verification consists of a single pairing execution then it is not even needed to assume that $\mathcal{D}^{\prime}$ has high min-entropy.

Choice of $\boldsymbol{\Delta}$. Recall that we need to find values for $\boldsymbol{\Delta}=(\alpha, \ldots)$, such that Crit $\cap \overline{\text { Crit }}=\emptyset$. For convenience sake, we require that the polynomials $\mathrm{crs}_{1}$ and $\mathrm{Crs}_{2}$ both contain a non-zero monomial corresponding to $Y^{0}=1$ (then we can publish $[1]_{1}$ and $[1]_{2}$ ) and that the values $i$, such that $j$ for which $f(X) Y^{j}$ belongs to the CRS for some $f(X)$, have as small absolute values as possible (this potentially speeds up the CRS verification algorithm ABLZ17, see Section 9). Since there are too many coefficients that one can take into account, we used a computer search to find the following values for $\alpha, \beta, \ldots$ :

$$
\begin{equation*}
\alpha=0, \quad \beta=1, \quad \gamma=-6, \quad \delta=4, \quad \eta=-1 . \tag{8}
\end{equation*}
$$

In this case, Crit $=\{2,-5,5,-2,-7,8\}$ and

$$
\begin{align*}
\operatorname{crsp} & =\binom{\left[\left\{u_{j}(x) y^{5}+v_{j}(x) y^{-5}+w_{j}(x) y^{2}\right\}_{j=m_{0}+1}^{m}, y^{0},\left\{x^{j} y^{1}\right\}_{j=0}^{n-1}\right]_{1},}{\left[\left\{x^{i} \ell(x) y^{2}\right\}_{j=0}^{n-2}, y^{-6}, y^{4}, y^{0} z,\left\{x^{j} y^{1} z\right\}_{j=0}^{n-1}\right]_{1},\left[y^{0},\left\{x^{j} y^{1}\right\}_{j=0}^{n-1}\right]_{2}}, \\
\operatorname{crs}_{\mathrm{V}} & =\left(\left[\left\{u_{j}(x) y^{6}+v_{j}(x) y^{-4}+w_{j}(x) y^{3}\right\}_{j=1}^{m_{0}}, y^{-6}\right]_{1},\left[y^{0}, y^{4}, y^{-1}, z\right]_{2},\left[y^{-7}\right]_{T}\right) . \tag{9}
\end{align*}
$$

Efficiency. $\mathrm{S}_{\text {qap }}$ has fewer trapdoors but otherwise the same complexity as Groth's knowledge-sound zk-SNARK Gro16, see Table 1 for a comparison. E.g., crsp has $\left(m-m_{0}\right)+1+n+(n-1)+1=m+2 n-m_{0}+1$ elements from $\mathbb{G}_{1}$ and $(n+2)$ elements from $\mathbb{G}_{2}$. Moreover, crsv has $m_{0}+1$ elements from $\mathbb{G}_{1}$, 3 elements from $\mathbb{G}_{2}$, and one element from $\mathbb{G}_{T}$. Since crsp and crsv have one common element in $\mathbb{G}_{1}$ then $\mid$ crs $\mid=(m+2 n+2) \mathfrak{g}_{1}+(n+4) \mathfrak{g}_{2}+\mathfrak{g}_{T}$. (Recall that $\mathfrak{g}_{\iota}$ denotes the representation length of an element of $\mathbb{G}_{\iota}$.) Clearly, [a] can be computed from $\left[y^{\alpha}\right]_{1}$ and $\left[x^{i} y^{\beta}\right]_{1}$ by using $n+1$ exponentiations, and it takes $\approx m+2 n$ additional exponentiations to compute $[\mathrm{c}]_{1}$.

## 5 SASE SNARK S ${ }_{\text {qap }}^{\text {se }}$ for QAP

Consider the case of simulation-extractability, where the adversary also can query the simulator. Let $\boldsymbol{\sigma}_{k}=\left(\sigma_{k j}\right)_{j=1}^{m_{0}}$ be the (maliciously generated) simulator
input used by the adversary during the $k$ th query. Let $\boldsymbol{X}=(X, \boldsymbol{Q}, \boldsymbol{D}, \boldsymbol{E}, Y)$ and $\boldsymbol{X}^{*}=(X, \boldsymbol{Q}, \boldsymbol{D}, \boldsymbol{E})$, where $D_{k}$ (resp., $E_{k}$ ) is the indeterminate corresponding to the random trapdoor $d$ (resp., e) generated by the simulator during the $k$ th query. In the case of SASE , in $\mathrm{S}_{\text {qap }}, \operatorname{crs}_{1}(a, \boldsymbol{X})$ and $\operatorname{crs} s_{2}(b, \boldsymbol{X})$ have additional addends (highlighted in what follows) that correspond to the indeterminates generated by the simulator oracle:

$$
\begin{aligned}
& \operatorname{crs}_{1}(a, \boldsymbol{X})=\ldots+\sum_{k} s_{a 1 k} D_{k}+\sum_{k} s_{a 2 k}\left(Y^{\delta-\alpha} D_{k}+Y^{-\alpha} D_{k} E_{k}+Y^{\gamma-\alpha} E_{k}\right)+ \\
& \sum_{k} s_{a 2 k} \sum_{j=1}^{m_{0}} \sigma_{k j}\left(u_{j}(X) Y^{\beta-\alpha+\delta}+v_{j}(X) Y^{\beta-\alpha+\gamma}+w_{j}(X) Y^{2 \beta-\alpha}\right) \\
& \operatorname{crs}_{2}(b, \boldsymbol{X})=\ldots+\sum_{k} s_{b k} E_{k}
\end{aligned}
$$

In this case, due to the extra inputs from the simulator, the critical coefficients of $V_{i}\left(\boldsymbol{X}^{*}\right)$ of $V(\boldsymbol{X})$ will be changed by extra addends $V_{i}^{+}\left(\boldsymbol{X}^{*}\right)$, depicted in Fig. 1. For example, $V_{\beta+\delta}\left(\boldsymbol{X}^{*}\right)=\left(b_{\delta}+1\right) u_{a}(X)-u(X)+a_{\delta} v_{b}(X)+\sum_{k}\left(s_{c 2 k}-\right.$ $\left.r_{b} s_{a 2 k}\right) \sum_{j} \sigma_{k j} u_{j}(X)$.

First, assume that the first verification equation is used. Then the coefficient of $Y^{-\alpha+\delta+\gamma} E_{k}$ of $V(\boldsymbol{X})$ (namely, $\left.\left(b_{\delta}+1\right) s_{a 2 k}\right)$ implies that $s_{a 2 k}=0$. Moreover, the coefficients of $Y^{\gamma+\delta}$ (namely, $b_{\delta}+a_{\gamma}\left(b_{\delta}+1\right)$ ), $Y^{\delta} D_{k}$ (namely, $r_{b} s_{a 2 k}-s_{c 2 k}+$ $\left.\left(b_{\delta}+1\right) s_{a 1 k}\right), Y^{\gamma} E_{k}$ (namely, $\left.r_{b} s_{a 2 k}-s_{c 2 k}+\left(a_{\gamma}+1\right) s_{b k}\right), Y^{\alpha} D_{k}$ (namely, $r_{b} s_{a 1 k}-$ $s_{c 1 k}$ ), and $D_{k} E_{k}$ (namely, $r_{b} s_{a 2 k}-s_{c 2 k}+s_{a 1 k} s_{b k}$ ) in $V(\boldsymbol{X})$ imply that either
(i) $s_{a 1 k}=s_{b k}=0$ and thus $s_{c 2 k}=r_{b} s_{a 2 k}=0$, for all $k$, or
(ii) $s_{a 1 k}=1 /\left(b_{\delta}+1\right)$ and $s_{b k}=b_{\delta}+1$ for at least one $k$.
(We note that we will not use all these coefficients in the actual SASE proof.)
In the first case, $s_{c 2 k}=r_{b} s_{a 2 k}$ for all $k$ and thus we can eliminate the $V_{i}^{+}\left(\boldsymbol{X}^{*}\right)$ addends in Fig. 1 , and thus get back to the (already solved) knowledge-soundness setting that guarantees us that $\chi(X)=0$.

In the second case, for some $k, A(\boldsymbol{X})=s_{a 1 k} D_{k}+\ldots$ and $B(\boldsymbol{X})=s_{b k} E_{k}+\ldots$ for $s_{a 1 k}=1 /\left(b_{\delta}+1\right) \neq 0$ and $s_{b k}=b_{\delta}+1 \neq 0$. Now, for $k_{1} \neq k_{2}$, the coefficient of $D_{k_{1}} E_{k_{2}}$ is $s_{a 1 k_{1}} s_{b k_{2}}=0$. Since $s_{a 1 k}=0$ iff $s_{b k}=0$, we get that $s_{a 1 k}, s_{b k} \neq 0$ for at most one index $k:=k_{0}$. Thus, the polynomials $V_{i}^{+}\left(\boldsymbol{X}^{*}\right)$ in Fig. 1 are equal to $\sum_{j} \sigma_{k_{0} j} u_{j}(X), \sum_{j} \sigma_{k_{0} j} v_{j}(X)$, and $\sum_{j} \sigma_{k_{0} j} w_{j}(X)$, respectively. Note also that $s_{a 2 k}=0$ and thus $s_{c 2 k}=1$.

To guarantee that the prover is honest, we must make it impossible for the prover to include a term $s_{a 1 k_{0}} D_{k_{0}}$, for non-zero $s_{a 1 k_{0}}$, to $A(\boldsymbol{X})$. The first idea how to achieve this is by asking the prover to additionally output $[\mathrm{b}]_{1}$ and then letting the verifier to check that $[\mathrm{b}]_{1} \bullet[1]_{2}=[1]_{1} \bullet[\mathrm{~b}]_{2}$. Since in the $k$ th query, the simulator also outputs $\left[\mathrm{b}_{k}\right]_{1}=\left[e_{k}\right]_{1}$, then now $A(\boldsymbol{X})$ also depends on $E_{k}$. That is, the polynomial $A(\boldsymbol{X})$ has an additional monomial $-\sum_{k} s_{a 3 k} E_{k}$ for each simulation query, and similarly for polynomial $B_{1}(\boldsymbol{X})=\ldots-\sum_{k} s_{b_{1} 3 k} E_{k}$. Thus, checking that $[\mathrm{b}]_{1} \bullet[1]_{2}=[1]_{1} \bullet[\mathrm{~b}]_{2}$ only guarantees that $B(\boldsymbol{X})=r_{b} Y^{\alpha}+$ $v_{b}(X) Y^{\beta}+\sum s_{b k_{0}} E_{k_{0}}$ for some $r_{b}, v_{b}(X)$, and (possibly non-zero) $s_{b k_{0}}=s_{b_{1} 3 k}$.

The problem here is that the added step can be seen as a knowledge-sound QA-NIZK argument $\Pi_{\text {sub }}$ JR13 that $[\mathrm{b}]_{2}$ belongs to the "subspace ${ }^{5}$ generated by $[\boldsymbol{M}(X, Y)]_{1}=\left[Y^{\alpha}, Y^{\beta}, X Y^{\beta}, \ldots, X^{n-1} Y^{\beta}\right]_{1}$. Since we allow for simulation queries, we need a simulation-extractable QA-NIZK argument for the subspace language. While such QA-NIZK arguments are known, they are not very efficient, KW15]. A saving grace for us is that it suffices for $\Pi_{s u b}$ to be one-time simulation-extractable (OTSE): that is, it suffices for $\Pi_{s u b}$ to be knowledgesound after one malicious query to the simulator. Really, as we argued before, it is possible that $s_{a 1 k}, s_{b k} \neq 0$ for at most one index $k=k_{0}$. More precisely, assume now that $s_{a 1 k_{0}}=s_{b k_{0}}=1$. Then, as seen from the coefficient of $Y^{-\alpha} D_{k_{1}} E_{k_{2}}^{2}$, $s_{a 2 k_{1}} s_{b k_{2}}=0$ for any $k_{1}, k_{2}$. Thus, $s_{b k_{0}}=0$ for any $k \neq k_{0}$.

Next, we use the main idea of the one-time simulation-sound (OTSS) QANIZK of Kiltz-Wee KW15, Section 3.3] $\Pi_{\text {otss }}$ by introducing a $\operatorname{tag} \tau$, and requiring that the simulation queries are made on tags $\tau_{k}$ that differ from the tag $\tau$ for which the malicious prover constructs a forgery attempt. (However, our construction is more efficient than $\Pi_{\text {otss }}$.) We introduce for this a new indeterminate $Z$, and ask the prover to compute the QA-NIZK argument with respect to the sum $\tau+Z$. This can be interpreted as making use of the pairwise independent function $H_{Z_{1}, Z_{2}}(\tau)=\tau Z_{1}+Z_{2}$ WC81. Note that also $\Pi_{\text {otss }}$ is somewhat inefficient and therefore we do use it directly.

Let $\boldsymbol{X}=(X, \boldsymbol{Q}, \boldsymbol{D}, \boldsymbol{E}, Y, Z)$ and $\boldsymbol{X}^{*}=\left(X, \boldsymbol{Q}_{1}, \boldsymbol{Q}_{2}, \boldsymbol{D}, \boldsymbol{E}, Z\right)$. Then,

$$
\begin{gathered}
\operatorname{crs}_{1}(a, \boldsymbol{X})=\sum_{j=1}^{m_{0}} a_{j}^{*}\left(u_{j}(X) Y^{\beta-\eta+\delta}+v_{j}(X) Y^{\beta-\eta+\gamma}+w_{j}(X) Y^{2 \beta-\eta}\right)+ \\
\sum_{i=m_{0}+1}^{m} a_{i}^{*}\left(u_{i}(X) Y^{\beta-\alpha+\delta}+v_{i}(X) Y^{\beta-\alpha+\gamma}+w_{i}(X) Y^{2 \beta-\alpha}\right)+ \\
h_{a}(X) \ell(X) Y^{2 \beta-\alpha}+r_{a} Y^{\alpha}+u_{a}(X) Y^{\beta}+a_{\gamma} Y^{\gamma}+a_{\delta} Y^{\delta}+\sum_{k} a_{q k} Q_{1 k}- \\
\sum_{k} s_{a 1 k} D_{k}+\sum_{k} s_{a 2 k}\left(Y^{\delta-\alpha} D_{k}+Y^{-\alpha} D_{k} E_{k}+Y^{\gamma-\alpha} E_{k}\right)+ \\
\sum_{k} s_{a 2 k} \sum_{j=1}^{m_{0}} \sigma_{k j}\left(u_{j}(X) Y^{\beta-\alpha+\delta}+v_{j}(X) Y^{\beta-\alpha+\gamma}+w_{j}(X) Y^{2 \beta-\alpha}\right)+ \\
r_{z a} Y^{\alpha} Z+u_{z a}(X) Y^{\beta} Z-\sum_{k} s_{a 3 k} E_{k}\left(\tau_{k}+Z\right), \\
c r s_{2}(b, \boldsymbol{X})=r_{b} Y^{\alpha}+v_{b}(X) Y^{\beta}+b_{\delta} Y^{\delta}+b_{\eta} Y^{\eta}+\sum_{k} b_{q k} Q_{2 k}+\sum_{k} s_{b k} E_{k} .
\end{gathered}
$$

where $u_{z a}(X) \in \mathbb{Z}_{p}^{(\leq n-1)}[X]$. Then, for example, $B_{1}(\boldsymbol{X})=c r s_{1}\left(b_{1}, \boldsymbol{X}\right)$. Recall that the verifier's second verification guarantees that for fixed $\tau$, the second verification polynomial $V^{s e}(\boldsymbol{X})$ satisfies $V^{s e}(\boldsymbol{x})=0$, where

$$
V^{s e}(\boldsymbol{X}):=B_{1}(\boldsymbol{X})-(\tau+Z) B(\boldsymbol{X})
$$

Consider again first the case $V^{s e}(\boldsymbol{x})=0$ as a polynomial. Looking at the coefficient of $E_{k}$ in $V^{s e}(\boldsymbol{X})$, we get $\tau_{k} s_{b_{1} 3 k}=-\tau s_{b k}$, while looking at the coefficient of $E_{k} Z$ in $V^{s e}(\boldsymbol{X})$, we get $s_{b_{1} 3 k}=-s_{b k}$. Since $\tau_{k} \neq \tau$, we get $s_{b_{1} 3 k}=s_{b k}=0$. From the earlier discussion, we obtain that $s_{a 1 k}=0$ and thus $s_{c 2 k}=r_{b} s_{a 2 k}$,

[^1]which means that the polynomials $V_{i}^{+}\left(\boldsymbol{X}^{*}\right)$ in Fig. 1 are equal to 0 and thus SASE of $\mathrm{S}_{\text {qap }}^{\text {se }}$ follows from the knowledge-soundness of $\mathrm{S}_{\text {qap }}$.

Due to the introduction of new indeterminate, we will have a larger set of critical coefficients. Let $\tilde{a}_{j}=a_{j}-\sum_{k} s_{c 2 k} \sigma_{k j}$ for $j \leq m_{0}$ and $\tilde{a}_{j}=c_{j}^{*}$ for $j>m_{0}$. Let $u(X)=\sum_{j=1}^{m} \tilde{a}_{j} u_{j}(X), v(X)=\sum_{j=1}^{m} \tilde{a}_{j} v_{j}(X)$, and $w(X)=\sum_{j=1}^{m} \tilde{a}_{j} w_{j}(X)$. Let $R^{\prime}=\left\{i=Y^{j_{0}} D_{k_{1}}^{j_{1}} E_{k_{1}}^{j_{2}} E_{k_{2}}^{j_{3}} Z^{j_{4}}: V_{i}\left(\boldsymbol{X}^{*}\right)=0\right\}$. Let $k=2 \beta$ and

$$
\text { Crit }^{\prime}=\left\{2 \beta, \beta+\gamma, \beta+\delta, \gamma+\delta, \gamma+\eta, 2 \delta, Y^{\gamma} D_{k_{1}}, E_{k_{1}}, E_{k_{1}} Z\right\}
$$

be the new set of critical coefficients. (Here, the first 6 coefficients are the same as in the case of $\mathrm{S}_{\text {qap. }}$.) Let $\overline{\text { Crit }^{\prime}}=R^{\prime} \backslash$ Crit $^{\prime}$.
Theorem 2. Let $\mathbf{R}=\operatorname{Inst}_{\text {qap }}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}, v_{j}, w_{j}\right\}_{j=0}^{m}\right)$ be a QAP instance. Let $\mathrm{S}_{\text {qap }}^{\text {se }}$ be the SASE SNARK (with highlighted entries) in Fig. 2.
(1) Assume $\boldsymbol{\Delta}$ is chosen so that $\mathrm{Crit}^{\prime} \cap \overline{\mathrm{Crit}^{\prime}}=\emptyset$. If the $(2 n-1, n-1)-P D L$ and $\mathcal{D}_{\mathbf{R}, \text { aux }_{\mathbf{R}}}^{\text {crs }}\left(\mathrm{S}_{\mathrm{qap}}^{\text {se }}\right)$-SAK assumptions hold then $\mathrm{S}_{\mathrm{qap}}^{\text {se }}$ in Fig. 2is ASE. If, additionally, $\mathbf{R}_{\text {Inst }_{\text {qap }}}$ is a hard-membership language then $\mathrm{S}_{\text {qap }}^{\text {se }}$ is $S A S E$.
(2) $\mathrm{S}_{\text {qap }}^{\text {se }}$ is perfectly zero-knowledge.

Proof. (1: ASE and SASE) First, let $\mathcal{A}$ be an ASE adversary that succeeded in outputting $(x, \pi)$ such that $x \notin \mathcal{L}$ but $V$ accepts. Since we are proving ASE, another part of the input to $\mathcal{A}$ is the reply of the $\operatorname{Sim}$ oracle to each query. Due to the use of a SAK assumption, $\mathbb{G}_{\iota}$-outputs of $\mathcal{A}$ have to belong to the span of her inputs (the elements of CRS, the simulator replies in $\mathbb{G}_{\iota}$, and $\left[\boldsymbol{q}_{\iota}\right]_{1}$ extracted from $\mathcal{A}$ ) and of new random group elements and moreover, one can extract the corresponding coordinates. When replying to $j$ th query, Sim samples fresh random integers $d_{j}$ and $e_{j}$. We model $d_{j}$ and $e_{j}$ as new indeterminates $D_{j}$ and $E_{j}$. Let $\boldsymbol{X}=(X, \boldsymbol{Q}, \boldsymbol{D}, \boldsymbol{E}, Y, Z)$ be the vector of all indeterminates and let $\boldsymbol{X}^{*}=(X, \boldsymbol{Q}, \boldsymbol{D}, \boldsymbol{E}, Z)$ be the vector of all indeterminates but $Y$.

Since the second verification equation holds, from the coefficients of $E_{k}$ (namely, $\tau_{k} s_{b_{1} 3 k}-\tau s_{b k}$ ) and $E_{k} Z$ (namely, $s_{b_{1} 3 k}-s_{b k}$ ) of $V^{s e}(\boldsymbol{X})=0$, we get $\left(\begin{array}{cc}\tau_{k} & -\tau \\ 1 & -1\end{array}\right)\binom{s_{b_{1}} 3 k}{s_{b k}}=\binom{0}{0}$. (Thus, the critical coefficients of the polynomial $V^{s e}(\boldsymbol{X})$ are $E_{k}$ and $E_{k} Z$, for each $k$.) Since $\tau \neq \tau_{k}$, the $2 \times 2$ matrix is invertible and thus $s_{a 1 k}=s_{b k}=0$. Then, from the coefficient of $Y^{\gamma} E_{k}$ (namely, $\left.r_{b} s_{a 2 k}+\left(a_{\gamma}+1\right) s_{b k}-s_{c 2 k}\right)$ of $V(\boldsymbol{X})=0$ we get that $s_{c 2 k}=r_{b} s_{a 2 k}$ for each $k$. Hence, the first three polynomials $V_{i}^{+}\left(\boldsymbol{X}^{*}\right)$ in Fig. 1 are all equal to 0 . The rest of the proof of ASE follows from the knowledge-soundness proof of Theorem 1.

To see that also SASE holds, note that from the ASE security proof it follows that a SASE adversary $\mathcal{A}$ cannot use the answers of simulation queries (produced when using a different tag) while creating an argument. This means that $\mathcal{A}$, after seeing a simulated argument for statement x , creates a new argument $\pi$ for the same statement (but under a different $\operatorname{tag} \tau$ ), but without the help of the oracle. Thus, $\mathcal{A}$ can be used to decide membership in the QAP language, a contradiction with the hard-membership property of $\mathbf{R}_{\text {Inst }_{\text {qap }}}$. Note that the SASE case cannot be purely reduced to knowledge-soundness, since it also must be impossible to create new arguments for true statements.
(2: zero-knowledge) similar to Theorem 1 .

## 6 SAP-Based SNARKs

In the following sections, we will describe SNARKs for different languages SAP, SSP, and QSP. Since these SNARKs and their security proofs are modifications of $S_{\text {qap }}$, we will omit most of the details.

Groth Gro16 and Groth and Maller GM17 used SAP (Square Arithmetic Programs) instead of QAP. The only algebraic distinction here is that $v(X)=$ $u(X)$ and thus $\mathbf{R}=\operatorname{Inst}_{\text {sap }}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}, w_{j}\right\}_{j=0}^{m}\right)$ is a SAP instance. $\mathbf{R}_{\text {lnst }_{\text {sap }}}$ is defined as $\mathbf{R}_{\text {Instap }_{\text {qap }}}$ in Eq. (1) except that $v(X)=u(X)$. Thus, each gate in the arithmetic circuit gets the same left and right inputs, or, putting it another way, the circuit consists of squaring gates only. Since each multiplication gate $c=a b$ can be implemented two squaring gates $\left(a b=(a / 2+b / 2)^{2}-(a / 2-b / 2)^{2}\right)$, one can verify the correctness of an arbitrary $d$-gate arithmetic circuit by transferring it to a circuit that has $\tilde{m} \leq 2 d$ squaring gates and then constructing a SNARK for SAP for the resulting circuit. The main motivation behind introducing SAP is that one can construct SNARK where $A(X, Y)=B(X, Y)$, which potentially makes the SNARK more efficient.

We will next describe how to modify our approach to the case of SAP. Since $u(X)=w(X)$, the corresponding key equation is $\chi_{\text {sap }}(X)=0$, where

$$
\chi_{\text {sap }}(X)=u(X)^{2}-w(X)-h(X) \ell(X) .
$$

In this case, we simplify Eqs. (3) and (4) by setting $v(X)=u(X)$ and $r_{a}=r_{b}$. Then $A(X, Y)=B(X, Y)=r_{a} Y^{\alpha}+u(X) Y^{\beta}$.

Thus, Eqs. (3) to (5) simplify to

$$
\begin{aligned}
& A(X, Y)=B(X, Y)=r_{a} Y^{\alpha}+u(X) Y^{\beta}, \\
& C(X, Y)=\left(A(X, Y)+Y^{\gamma}\right)\left(A(X, Y)+Y^{\delta}\right)-Y^{\gamma+\delta} \\
& \quad=u(X)\left(Y^{\beta+\gamma}+Y^{\beta+\delta}\right)+u(X)^{2} Y^{2 \beta}+r_{a}\left(r_{a} Y^{\alpha}+2 u(X) Y^{\beta}+Y^{\gamma}+Y^{\delta}\right) Y^{\alpha}, \\
& \quad=\left(u(X)\left(Y^{\beta+\gamma}+Y^{\beta+\delta}\right)+w(X) Y^{2 \beta}\right)+\left(u(X)^{2}-w(X)\right) Y^{2 \beta}+ \\
& \quad r_{a}\left(r_{a} Y^{\alpha}+2 u(X) Y^{\beta}+Y^{\gamma}+Y^{\delta}\right) Y^{\alpha}, \\
& C_{p}(X, Y)=\sum_{j=1}^{m_{0}} a_{j}\left(u_{j}(X)\left(Y^{\beta-\eta+\gamma}+Y^{\beta-\eta+\delta}\right)+w_{j}(X) Y^{2 \beta-\eta}\right), \\
& C_{s}(X, Y)=\sum_{j=m_{0}+1}^{m} a_{j}\left(u_{j}(X)\left(Y^{\beta-\alpha+\gamma}+Y^{\beta-\alpha+\delta}\right)+w_{j}(X) Y^{2 \beta-\alpha}\right)+ \\
& \quad h(X) \ell(X) Y^{2 \beta-\alpha}+r_{a}\left(r_{a} Y^{\alpha}+2 u(X) Y^{\beta}+Y^{\gamma}+Y^{\delta}\right) .
\end{aligned}
$$

We construct the SNARK $\mathrm{S}_{\text {sap }}$ by correspondingly simplifying Fig. 2, see Fig. 3 We can find a suitable $\boldsymbol{\Delta}$ as in the case of QAP in Section 4. see Eq. (8).

Knowledge-soundness. Since $S_{\text {sap }}$ is an optimized version of $S_{\text {qap }}$, its knowledge-soundness can be proven by using the same approach. That is, one can follow the proof of Theorem 1. Let $h(X):=h_{c}(X)-r_{a} h_{a}(X)$. Let

$$
\tilde{a}_{j}= \begin{cases}a_{j}-b_{\eta} a_{j}^{*}, & j \leq m_{0} \\ c_{j}^{*}-r_{a} a_{j}^{*}, & j>m_{0}\end{cases}
$$

```
\(\mathrm{K}_{\mathrm{crs}}\left(\mathbf{R}\right.\), aux \(\left._{\mathbf{R}}\right):\) Sample \(x, y, z \leftarrow \$ \mathbb{Z}_{p}^{*}\), let \(\mathrm{td} \leftarrow(x, y, z)\). Let

    return \(\pi \leftarrow\left(\left[\mathrm{a}, \mathrm{c}_{s}\right]_{1},[\mathrm{~b}]_{2}\right)\);
```

Fig. 3. The new SNARKs for SAP and SSP: knowledge-sound S sap $^{\text {s without highlighted }}$ entries) and SASE $\mathrm{S}_{\text {sap }}^{\text {se }}$ (with highlighted entries). $\mathrm{S}_{\text {spp }}$ is like $\mathrm{S}_{\text {sap }}$ and $\mathrm{S}_{\text {ssp }}^{\text {se }}$ is like $\mathrm{S}_{\text {sap }}^{\text {se }}$, except that then also $w_{j}(X)=u_{j}(X)$.

Denote $u(X)=\sum_{j=1}^{m} \tilde{a}_{j} u_{j}(X)$ and $w(X)=\sum_{j=1}^{m} \tilde{a}_{j} w_{j}(X)$. In this case, the "significant" coefficients $V_{i}(X, \boldsymbol{Q}), i \in$ Crit, of $V(\boldsymbol{X})$ are depicted in Fig. 4. The differences compared to Fig. 1 are solely due to the setting $v(X)=u(X)$.

Theorem 3. Let $\mathbf{R}=\operatorname{Inst}_{\text {sap }}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}, w_{j}\right\}_{j=0}^{m}\right)$ be a SAP instance.
(1) Assume $\boldsymbol{\Delta}$ is chosen so that $\mathrm{Crit} \cap \overline{\mathrm{Crit}}=\emptyset$. If the $(2 n-1, n-1)-P D L$ and $\mathcal{D}_{\mathbf{R}, \text { aux }_{\mathbf{R}}}^{\text {crs }}\left(\mathrm{S}_{\mathrm{sap}}\right)$-SAK assumptions hold then $\mathrm{S}_{\text {sap }}$ in Fig. 2 is knowledge-sound.
(2) $\mathrm{S}_{\text {sap }}$ is perfectly zero-knowledge.

Fig. 4. Critical coefficients in $\mathrm{S}_{\text {sap }}$ (left, $\tau=1$ ) and addends to the same coefficients in the SASE case (right).

Proof (Sketch). (1: knowledge-soundness) Since the rest of the knowledgesound is essentially the same as in the proof of Theorem 1, we only reprove the Step 1 from that proof.

Consider the polynomials in Fig. 4. Since $b_{\delta}+a_{\gamma}\left(b_{\delta}+1\right)=0$, we get $a_{\gamma}=$ $-b_{\delta} /\left(b_{\delta}+1\right)$ and $a_{\gamma}, b_{\delta} \neq-1$ and $\left(a_{\gamma}+1\right)\left(b_{\delta}+1\right)=1$. Thus $a_{\delta}=b_{\eta}=0$, which means that $\tilde{a}_{j}=a_{j}$ for $j \leq m_{0}$. Thus, $u_{a}(X) v_{b}(X)=u(X)^{2}$ and $u(X)^{2}-w(X)=$ $h(X) \ell(X)$, which means that $\chi_{\text {sap }}(X)=0$.
(2: zero-knowledge) as in Theorem 1, except that we use only one new trapdoor $d$ due to the fact that $\mathrm{a}=\mathrm{b}$.

Efficiency. Clearly, in $\mathrm{S}_{\text {sap }}$, the CRS has $(n)+(n-1)+m+2=2 n+m+1$ elements from $\mathbb{G}_{1}$ and $n+3$ elements from $\mathbb{G}_{2}$. The prover's computation is $n+1$ exponentiations to compute $[\mathrm{a}]_{1}, n+1$ exponentiations to compute $[\mathrm{b}]_{2}$, and $1+\left(m-m_{0}\right)+(n-1)=n+m-m_{0}$ exponentiations to compute $\left[\mathrm{c}_{s}\right]_{1}$.

SASE SNARK S $\mathbf{S}_{\text {sap }}^{\text {se }}$. Consider the case of SASE with $\mathrm{S}_{\text {sap }}$. Taking into account answers from simulation queries, the polynomials $\mathrm{crs} s_{1}$ and $\mathrm{cr} s_{2}$ have the following new addends:

$$
\begin{aligned}
& \operatorname{crs}_{1}(a, \boldsymbol{X})=\ldots+\sum_{k} s_{a 1 k} D_{k}+\sum_{k} s_{a 2 k}\left(Y^{\delta-\alpha}+Y^{-\alpha} D_{k}+Y^{\gamma-\alpha}\right) D_{k}+ \\
& \quad \sum_{k} s_{a 2 k} \sum_{j=1}^{m_{0}} \sigma_{k j}\left(u_{j}(X) Y^{\beta-\alpha+\delta}+u_{j}(X) Y^{\beta-\alpha+\gamma}+w_{j}(X) Y^{2 \beta-\alpha}\right), \\
& \operatorname{crs}_{2}(b, \boldsymbol{X})=\ldots+\sum_{k} s_{b k} D_{k} .
\end{aligned}
$$

(Compared to $\mathrm{S}_{\text {qap }}^{\text {se }}$, we just changed $v_{j}(X)$ to $u_{j}(X)$ and $E_{k}$ to $D_{k}$.) In the honest case, $[\mathrm{a}]_{1} \bullet[1]_{2}=[1]_{1} \bullet[\mathrm{~b}]_{2}$. However, if the verifier additionally checks that $[\mathrm{a}]_{1} \bullet[1]_{2}=[1]_{1} \bullet[\mathrm{~b}]_{2}$, one obtains the guarantee that $A(\boldsymbol{X})=B(\boldsymbol{X})=r_{a} Y^{\alpha}+$ $u_{a}(X) Y^{\beta}-\sum s_{a 1 k} D_{k}$. Again, this does not guarantee simulation-extractability.

We proceed similarly to the case of $\mathrm{S}_{\text {qap }}^{\text {se }}$ but take advantage of the fact that $\mathrm{a}=\mathrm{b}$ in the honest case. Recall that in $\mathrm{S}_{\text {qap }}^{\text {se }}$, one constructed $\mathrm{b}_{1}$, such that $\mathrm{b}_{1}=\mathrm{b}(\tau+z)$ (where $\tau$ is a tag and $Z$ is a new indeterminate). What we do next is to define $\mathrm{a}=\mathrm{b}_{1}$, and then modify the verification equations to take that into
account, as in Fig. 3 This defines two verification polynomials,

$$
\begin{aligned}
V(\boldsymbol{X})= & \left(A(\boldsymbol{X})+(\tau+Z) Y^{\gamma}\right)\left(B(\boldsymbol{X})+Y^{\delta}\right)-(\tau+Z) C_{p}(\boldsymbol{X}) Y^{\eta}- \\
& (\tau+Z) C_{s}(\boldsymbol{X}) Y^{\alpha}-(\tau+Z) Y^{\gamma+\delta}, \\
V^{s e}(\boldsymbol{X})= & A(\boldsymbol{X})-(\tau+Z) B(\boldsymbol{X}) .
\end{aligned}
$$

After this, the CRS has to additionally include some new elements (highlighted in Fig. 3). This changes the polynomials $\mathrm{cr} s_{1}$ and $\mathrm{cr} s_{2}$ to

$$
\begin{gathered}
\operatorname{crs}_{1}(a, \boldsymbol{X})=\sum_{j=1}^{m_{0}} a_{j}^{*}\left(u_{j}(X) Y^{\beta-\eta+\delta}+u_{j}(X) Y^{\beta-\eta+\gamma}+w_{j}(X) Y^{2 \beta-\eta}\right)+ \\
\sum_{i=m_{0}+1}^{m} a_{i}^{*}\left(u_{i}(X) Y^{\beta-\alpha+\delta}+u_{i}(X) Y^{\beta-\alpha+\gamma}+w_{i}(X) Y^{2 \beta-\alpha}\right)+ \\
h_{a}(X) \ell(X) Y^{2 \beta-\alpha}+r_{a} Y^{\alpha}+u_{a}(X) Y^{\beta}+a_{\gamma} Y^{\gamma}+a_{\delta} Y^{\delta}+\sum_{k} a_{q k} Q_{1 k}- \\
\sum_{k} s_{a 1 k}\left(\tau_{k}+Z\right) D_{k}+\sum_{k} s_{a 2 k}\left(Y^{\delta-\alpha} D_{k}+Y^{-\alpha} D_{k}^{2}+Y^{\gamma-\alpha} D_{k}\right)+ \\
\sum_{k} s_{a 2 k} \sum_{j=1}^{m_{0}} \sigma_{k j}\left(u_{j}(X) Y^{\beta-\alpha+\delta}+u_{j}(X) Y^{\beta-\alpha+\gamma}+w_{j}(X) Y^{2 \beta-\alpha}\right)+ \\
a_{Y^{\alpha} Z} Y^{\alpha} Z+u_{z a}(X) Y^{\beta} Z+a_{Z} Z+a_{\gamma z} Y^{\gamma} Z, \\
\operatorname{crs}_{2}(b, \boldsymbol{X})=r_{b} Y^{\alpha}+u_{b}(X) Y^{\beta}+b_{\delta} Y^{\delta}+b_{\eta} Y^{\eta}+\sum_{k} b_{q k} Q_{2 k}+ \\
\sum_{k} s_{b k} D_{k}+b_{\alpha z} Y^{\alpha} Z+b_{\eta z} Y^{\eta} Z .
\end{gathered}
$$

Since the second verification accepts holds, then $V^{\text {se }}(\boldsymbol{x})=0$. If $V^{\text {se }}(\boldsymbol{X})=$ 0 as a polynomial then $A(\boldsymbol{X})=(\tau+Z) B(\boldsymbol{X})$, and from the coefficients of $D_{k}$ and $D_{k} Z$ of $V^{s e}(\boldsymbol{X})$ we get $\tau_{k} s_{a 1 k}=\tau s_{b k}$ and $s_{a 1 k}=s_{b k}$. Since $\tau \neq \tau_{k}$, this means $s_{a 1 k}=s_{b k}=0$. From the coefficient of $Y^{\gamma} D_{k}$ of $V(\boldsymbol{X})$, we get $r_{b} s_{a 2 k_{1}}-\tau s_{c 2 k_{1}}+s_{b k_{2}}\left(A_{\gamma}+\tau\right)=0$. and thus $\tau s_{c 2 k_{1}}=r_{b} s_{a 2 k_{1}}$. Thus means that $V_{i}^{+}\left(\boldsymbol{X}^{*}\right)=0$ in Fig. 4 and thus, analogously to the case of $\mathrm{S}_{\text {qap }}^{\text {se }}, \mathrm{SASE}$ of $\mathrm{S}_{\text {sap }}^{\text {se }}$ can be reduced to the knowledge-soundness of $\mathrm{S}_{\text {sap }}$ and the hardness of SAP.

Theorem 4. Let $\mathbf{R}=$ Inst $_{\text {sap }}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}, w_{j}\right\}_{j=0}^{m}\right)$ be a SAP instance.
(1) Assume $\boldsymbol{\Delta}$ is chosen so that Crit $^{\prime} \cap \overline{\text { Crit }^{\prime}}=\emptyset$. If the $(2 n-1, n-1)-P D L$ and $\mathcal{D}_{\mathbf{R}, \mathrm{au} \mathrm{\times}}^{\mathbf{R}}$ ( $\left.\mathrm{S}_{\text {sap }}^{\text {se }}\right)$-SAK assumptions hold then $\mathrm{S}_{\text {sap }}^{\text {se }}$ in Fig. 3 is ASE. If, additionally, $\mathbf{R}_{\text {Inst }_{\text {spp }}}$ is a hard-membership language then $\mathrm{S}_{\text {sap }}^{\mathrm{se}}$ is $S A S E$.
(2) $\mathrm{S}_{\text {sap }}^{\text {se }}$ is perfectly zero-knowledge.

Efficiency. Clearly, in $\mathrm{S}_{\text {sap }}^{\text {se }}$, the CRS has $(n)+(n-1)+m+2+(n+3)=3 n+m+4$ elements from $\mathbb{G}_{1}$ and $n+5$ elements from $\mathbb{G}_{2}$. The prover's computation is $n+1+1=n+2$ exponentiations to compute $[\mathrm{a}]_{1}, n+1$ exponentiations to compute $[\mathrm{b}]_{2}$, and $1+\left(m-m_{0}\right)+(n-1)=n+m-m_{0}$ exponentiations to compute $\left[\mathrm{c}_{s}\right]_{1}$. The verifier executes 5 pairings and $m_{0}+4$ exponentiations.

## 7 SSP-Based SNARKs

In this section, we will construct a knowledge-sound SNARK $\mathrm{S}_{\text {ssp }}$ and a SASE SNARK S ${ }_{\text {ssp }}^{\text {se }}$ for SSP (Square Span Programs, DFGK14). We recall that by
using SSP, one can prove that different linear combinations of witness coefficients are simultaneously Boolean. As shown in [DFGK14], this is sufficient to show that a Boolean circuit has been correctly evaluated on (secret or public) inputs:

- For each wire, one checks that the wire value is Boolean.
- For each gate, one can check that it has implemented its Boolean function correctly by checking that certain linear combination of its input and output wire values is Boolean. For example, $a \bar{\wedge} b=c$ iff $a+b+2 c-2 \in\{0,1\}$ and $a \oplus b=c$ iff $(a+b+c) / 2 \in\{0,1\}$ DFGK14.

Thus, one can implement SSP by using a QAP-type approach, by checking $n=d+m$ constraints of type $\left(\sum_{j=1}^{m} U_{i j} a_{j}\right)^{2}=\sum_{j=1}^{m} U_{i j} a_{j}, i \in[1 . . n]$, where $d$ is the number of the gates and $m$ is the number of the wires. (In a QAPbased approach for arithmetic circuits, $n=d$.) Based on this observation, we design $\mathrm{S}_{\text {ssp }}$ around the verification equation as in Section 4 . The only difference in the language is that $u(X)=v(X)=w(X)$, and thus the key equation is $\chi_{s s p}(X)=0$, where

$$
\chi_{s s p}(X)=u(X)(u(X)-1)-h(X) \ell(X)
$$

Thus, $h(X)=u(X)(u(X)-1) / \ell(X)$ is a polynomial iff the prover is honest. The new SNARK $\mathrm{S}_{\text {ssp }}$ for SSP in Fig. 3 is like $\mathrm{S}_{\text {sap }}$, except that now we have $u_{j}(X)=v_{j}(X)=w_{j}(X)$ instead of just $u_{j}(X)=v_{j}(X)$.

Let $\mathbf{R}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}\right\}_{j=0}^{m}\right)$ be a SSP instance. $\mathbf{R}_{\text {lnst }_{\text {spp }}}$ is defined as $\mathbf{R}_{\text {lnst }_{\text {qap }}}$ in Eq. (1) except that $u(X)=v(X)=w(X)$.

Theorem 5. Let $\mathbf{R}=\operatorname{lnst}_{\text {ssp }}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}\right\}_{j=0}^{m}\right)$ be a SSP instance.
(1) Assume $\boldsymbol{\Delta}$ is chosen so that $\mathrm{Crit} \cap \overline{\mathrm{Crit}}=\emptyset$. If the $(2 n-1, n-1)-P D L$ and $\mathcal{D}_{\mathbf{R}, \text { aux }_{\mathbf{R}}}^{\text {crs }}\left(\mathrm{S}_{\text {ssp }}\right)$-SAK assumptions hold then $\mathrm{S}_{\text {ssp }}$ in Fig. 3 is knowledge-sound.
(2) $\mathrm{S}_{\mathrm{ssp}}$ is perfectly zero-knowledge.

Proof. Follows directly from Theorem 3 .
Importantly, since $a_{j}$ are Boolean, it is cheaper to compute say $\left[u(X) u^{\beta}\right]_{1} \leftarrow$ $\sum_{j=1}^{m} a_{j}\left[u_{j}(X) y^{\beta}\right]_{1}$ : this requires $m$ multiplications compared to $n$ exponentiations in the case of QAP and SAP. (Here, and in the next section, we count the number of multiplications in the worst case. In the average case, it will be reduce by a factor of two.) Moreover, setting $w_{j}(X)=u_{j}(X)$ allows for additional minor optimizations. For example, to compute $[a]_{1}$ and $\left[\mathrm{c}_{s}\right]_{1}$, the prover can first set $\left[u^{\prime}\right]_{1} \leftarrow r_{a}\left[y^{\alpha}\right]_{1} ;\left[u^{\prime \prime}\right]_{1} \leftarrow \sum_{j=1}^{m} a_{j}\left[u_{j}(x) y^{\beta}\right]_{1}$, and then $[\mathrm{a}]_{1} \leftarrow \tau \cdot\left(\left[u^{\prime}\right]_{1}+\left[u^{\prime \prime}\right]_{1}\right)+r_{a}\left[y^{\alpha} z\right]_{1}+\sum_{j=1}^{m} a_{j}\left[u_{j}(x) y^{\beta} z\right]_{1}$ and $\left[\mathrm{c}_{s}\right]_{1} \leftarrow$ $\sum_{j=m_{0}+1}^{m} a_{j}\left[u_{j}(x) y^{\beta-\alpha+\delta}+u_{j}(x) y^{\beta-\alpha+\gamma}+w_{j}(x) y^{2 \beta-\alpha}\right]_{1}+\left[h(x) \ell(x) y^{2 \beta-\alpha}\right]_{1}+$ $r_{a}\left(\left[u^{\prime}\right]_{1}+2\left[u^{\prime \prime}\right]_{1}+\left[y^{\gamma}\right]_{1}+\left[y^{\delta}\right]_{1}\right)$. Thus, the prover spends one exponentiation and $m$ multiplications in $\mathbb{G}_{1}$ to compute $\left[u^{\prime}\right]_{1}$ and $\left[u^{\prime \prime}\right]_{1}$, and additional $m-m_{0}$ multiplications and $(n-1)+1=n$ exponentiations in $\mathbb{G}_{1}$ to compute $\left[c_{s}\right]_{1}$. She also spends 1 exponentiation and $m$ multiplications in $\mathbb{G}_{2}$ to compute $[\mathrm{b}]_{2}$.

SASE SNARK $\mathbf{S}_{\text {ssp }}^{\text {se }} . \mathbf{S}_{\mathbf{s s p}}^{\text {se }}$ is defined as $\mathbf{S}_{\text {sap }}^{\text {se }}$, setting $w_{j}(X)=u_{j}(X)$.
Theorem 6. Let $\mathbf{R}=\operatorname{Inst}_{\text {ssp }}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}\right\}_{j=0}^{m}\right)$ be a SSP instance.
(1) Assume $\boldsymbol{\Delta}$ is chosen so that $\mathrm{Crit}^{\prime} \cap \overline{\mathrm{Crit}^{\prime}}=\emptyset$. If the $(2 n-1, n-1)-P D L$ and $\mathcal{D}_{\mathbf{R}, \text { aux }_{\mathbf{R}}}^{\mathrm{crs}}\left(\mathrm{S}_{\mathbf{s s p}}^{\mathrm{se}}\right)$-SAK assumptions hold then $\mathrm{S}_{\mathbf{s s p}}^{\mathrm{se}}$ in Fig. 3 is ASE. If, additionally, $\mathbf{R}_{\text {Instspp }}$ is a hard-membership language then $\mathrm{S}_{\mathrm{ssp}}^{\mathrm{se}}$ is $S A S E$.
(2) $\mathrm{S}_{\mathrm{ssp}}^{\mathrm{se}}$ is perfectly zero-knowledge.

Efficiency-wise, $\mathrm{S}_{\text {ssp }}^{\text {se }}$ is like $\mathrm{S}_{\text {sap }}^{\text {se }}$, except that the prover needs to compute $3 m-m_{0}$ multiplications and $n+2$ exponentiations in $\mathbb{G}_{1}$ and 1 exponentiation and $m$ multiplications in $\mathbb{G}_{2}$.

## 8 QSP-Based SNARKs

In addition to QAP, Gennaro et al. GGPR13 proposed another formalism called QSP (Quadratic Span Program). This approach was further optimized by Lipmaa Lip13. Without going to full details, we mention that there exists a reduction from Boolean circuit satisfiability to QSPs. The reduction itself is not as efficient than the reduction to SSPs, and in particular, the size of the QSP, given the same circuit, is considerably larger than that of the SSP. (According to DFGK14, if the circuit has $m$ wires and $n$ gates, SSP matrices have size $\approx m \times(m+n)$ while QSP matrices have size $\approx 14 n \times 11 n$.) However, QSP-based solutions like the SSP-based solutions have a short argument and CRS. They also result in 2-query linear PCPs for Circuit-SAT, $\mathrm{BCI}^{+} 13$ Lip13].

In this section, we assume that one has already constructed a reduction to the QSP. Given now a concrete QSP instance, we construct a knowledge-sound and a SASE SNARK fo QSP. We also assume that the QSP matrix size is $n \times m$ (thus, $n$ and $m$ do not correspond to the circuit size anymore.)

In the case of QSP [GGPR13 Lip13], $w(X)=0$ and thus the key equation is

$$
\chi_{q s p}(X)=u(X) v(X)-h(X) \ell(X)=0 .
$$

We now construct the SNARK $\mathrm{S}_{\mathrm{qsp}}$, see Fig. 2 (the case $w_{j}(X)=u_{j}(X)$ ). Thus, each cost parameter is the same as in the case of $S_{\text {qap }}$ except that there are significantly more constraints (that are hidden in the reduction from circuits to QSP, $(\operatorname{Lip} 13)$ and thus $n$ is larger.

Let $\mathbf{R}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}, v_{j}\right\}_{j=0}^{m}\right)$ be a QSP instance. $\mathbf{R}_{\text {Inst }_{\text {qup }}}$ is defined as $\mathbf{R}_{\text {Inst }_{\text {qap }}}$ in Eq. (1) except that $w(X)=0$.

Theorem 7. Let $\mathbf{R}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}, v_{j}\right\}_{j=0}^{m}\right)$ be a QSP instance.
(1) Assume $\boldsymbol{\Delta}$ is chosen so that Crit $\cap \overline{\text { Crit }}=\emptyset$. If the $(2 n-1, n-1)-P D L$ and $\mathcal{D}_{\mathbf{R}, \text { aux }}^{\mathbf{R}}$ crs $\left(\mathrm{S}_{\mathrm{qsp}}\right)$-SAK assumptions hold then $\mathrm{S}_{\mathrm{qsp}}$ in Fig. 2 is knowledge-sound. (2) $\mathrm{S}_{\mathrm{qsp}}$ is perfectly zero-knowledge.

As in the case of SSP, since the witness is Boolean, we can significantly speed up the prover's computation. Really, the prover computes [a] ${ }_{1} \leftarrow$
$r_{a}\left[y^{\alpha}\right]_{1}+\sum_{j=1}^{m} a_{j}\left[u_{j}(x) y^{\beta}\right]_{1},[\mathrm{~b}]_{2} \leftarrow r_{b}\left[y^{\alpha}\right]_{2}+\sum_{j=1}^{m} a_{j}\left[v_{j}(x) y^{\beta}\right]_{2}$, and $\left[\mathrm{c}_{s}\right]_{1} \leftarrow$ $\sum_{j=m_{0}+1}^{m} a_{j}\left[u_{j}(x) y^{\beta-\alpha+\delta}+v_{j}(x) y^{\beta-\alpha+\gamma}\right]_{1}+\left[h(x) \ell(x) y^{2 \beta-\alpha}\right]_{1}+r_{b}\left([\mathrm{a}]_{1}+\left[y^{\gamma}\right]_{1}\right)+$ $r_{a}\left(\left[y^{\delta}\right]_{1}+\sum_{j=1}^{m} a_{j}\left[v_{j}(x) y^{\beta}\right]_{1}\right)$. Thus, the prover executes $1+1+((n-1)+1)=n+2$ exponentiations and $m+m+\left(\left(m-m_{0}\right)+m\right)=4 m-m_{0}$ multiplications in $\mathbb{G}_{1}$ and 1 exponentiation and $m$ multiplications in $\mathbb{G}_{2}$.

SASE SNARK $\mathbf{S}_{\mathbf{q s p}}^{\text {se }}$. One obtains a SASE version of $\mathrm{S}_{\text {qsp }}$ exactly as in the case of $\mathrm{S}_{\text {qap }}$ in Section 4 . Thus, $\mathrm{S}_{\text {qsp }}^{\text {se }}$ is like $\mathrm{S}_{\text {qap }}^{\text {se }}$, except that $w_{j}(X)=0$.
Theorem 8. Let $\mathbf{R}=\left(\mathbb{Z}_{p}, m_{0},\left\{u_{j}, v_{j}\right\}_{j=0}^{m}\right)$ be a QSP instance.
(1) Assume $\boldsymbol{\Delta}$ is chosen so that $\mathrm{Crit}^{\prime} \cap \mathrm{Crit}^{\prime}=\emptyset$. If the $(2 n-1, n-1)-P D L$ and $\mathcal{D}_{\mathbf{R}, \mathrm{aux}_{\mathbf{R}}}^{\text {crs }}\left(\mathrm{S}_{\mathrm{qsp}}^{\text {se }}\right)$-SAK assumptions hold then $\mathrm{S}_{\mathrm{qsp}}^{\text {se }}$ in Fig. 2 is ASE. If, additionally, $\mathbf{R}_{\text {Inst }_{\text {qsp }}}$ is a hard-membership language then $\mathrm{S}_{\mathrm{qsp}}^{\mathrm{se}}$ is $S A S E$.
(2) $\mathrm{S}_{\mathrm{qsp}}^{\mathrm{se}}$ is perfectly zero-knowledge.

Efficiency-wise, compared to $\mathrm{S}_{\text {qsp }}$, the prover additionally computes $\left[\mathrm{b}_{1}\right]_{1} \leftarrow$ $r_{b}\left(\tau\left[y^{\alpha}\right]_{1}+\left[y^{\alpha} z\right]_{1}\right)+\tau \sum_{j=1}^{m} a_{j}\left[v_{j}(x) y^{\beta}\right]_{1}+\sum_{j=1}^{m} a_{j}\left[v_{j}(x) y^{\beta} z\right]_{1}$, which takes 3 exponentiations and $m$ additional multiplications (since $\sum_{j=1}^{m} a_{j}\left[v_{j}(x) y^{\beta}\right]_{1}$ is already computed) in $\mathbb{G}_{1}$.

## 9 Discussion

Subversion-Zero Knowledge. In a subversion zero-knowledge (Sub-ZK) SNARK BFS16ABLZ17|Fuc18, one wants to obtain zero-knowledge even in the case the CRS creator cannot be trusted. As noted in ALSZ18, Sub-ZK is equivalent to non-auxiliary-string non-black-box zero knowledge in the weak bare public key (BPK, CGGM00|MR01]) model.

Let us show that under the setting in Eq. (8) with CRS as in Eq. (9), the correctness (i.e., that it corresponds to some choice of trapdoors) of the CRS of $\mathrm{S}_{\text {qap }}^{\text {se }}$ and thus also of $\mathrm{S}_{\text {qap }}$ can be verified by using a public CV algorithm. Note that here we assume $u_{j}(X)=\sum u_{j i} X^{i}, v_{j}(X)=\sum v_{j i} X^{i}$, and $w_{j}(X)=$ $\sum w_{j i} X^{i}$. The only problem one encounters is the check that $y^{\delta}=y^{4}$ is correctly computed. We deal with it by introducing a random trapdoor $t$, adding $\mathrm{crs}_{\mathrm{cv}}:=$ $\left[t, y^{2} t, y^{4} t\right]_{1}$ to the CRS, and then additionally verifying the correctness of $\mathrm{crs}_{\mathrm{Cv}}$. Clearly, inclusion of such elements does not change the critical coefficients from Crit. Alternatively, one can define new trapdoors $s$ and $t$ instead of $y^{\gamma}=y^{-6}$ and $y^{\delta}=y^{4}$, but then (in the case of $\mathrm{S}_{\text {qap }}^{\text {se }}$ ) one would have the setting of 5 independent trapdoors ( $x, y, z, s, t$ ) again.

The existence of public CV can be used to make $S_{\text {qap }}$ and $S_{\text {qap }}^{\text {se }}$ subversionresistant, by using the techniques of ABLZ17]. In particular, if CV accepts crs, one can use the BDH-KE assumption ABLZ17 to extract $y$ and then use extracted $y$ to simulate the argument. Note that CV can be sped up significantly by using batching techniques as explained in ABLZ17.

CV for other new SNARKs is very similar: it is essentially the same for knowledge-sound versions while the added CRS elements in the SASE versions are trivially verifiable due to $[1]_{1}$ and $[z]_{2}$ being a part of the CRS.

```
\(\mathrm{CV}\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}, \mathrm{crs}, \mathrm{crs} \mathrm{cv}\right)\) :
    Check that the following holds:
    // Trapdoors are not 0:
    \([x y]_{1} \neq[0]_{1} ;[t]_{1} \neq[0]_{1} ;[z]_{1} \neq[0]_{1} ;\)
    \(/ /\) The bracketed element in \(\mathbb{G}_{1}\) and \(\mathbb{G}_{2}\) are consistent:
    \(\left[y^{4}\right]_{1} \bullet[1]_{2}=[1]_{1} \bullet\left[y^{4}\right]_{2} ;[z]_{1} \bullet[1]_{2}=[1]_{1} \bullet[z]_{2} ;\)
    for \(j=0\) to \(n-1\) do \(\left[x^{j} y\right]_{1} \bullet[1]_{2}=[1]_{1} \bullet\left[x^{j} y\right]_{2} ;\) endfor
    // Degrees of \(y^{i}\) are consistent:
    \([y]_{1} \bullet\left[y^{-1}\right]_{2}=[1]_{1} \bullet[1]_{2} ;\left[y^{2} t\right]_{1} \bullet\left[y^{-1}\right]_{2}=[t]_{1} \bullet[y]_{2} ;\)
    \(\left[y^{4} t\right]_{1} \bullet\left[y^{-1}\right]_{2}=\left[y^{2} t\right]_{1} \bullet[y]_{2} ;[t]_{1} \bullet\left[y^{4}\right]_{2}=\left[y^{4} t\right]_{1} \bullet[1]_{2} ;\)
    \(\left[y^{-6}\right]_{1} \bullet\left[y^{4}\right]_{2}=[y]_{1} \bullet[y]_{2} ;\)
    // Degrees of \(x^{j} y\) are consistent:

    endfor
```

Fig. 5. The CRS verification algorithm $C V$ in $S_{\text {qap }}$ and $S_{\text {qap }}^{\text {se }}$ (with highlighted entries)

Application: UC-Secure SNARKs. One can plug in $S_{\text {qap }}^{\text {se }}$ (instead of the Groth's SNARK as done in KZM $^{+} 15$ or the Groth-Maller SNARK as done in Bag19) to the known transformation of non-black-box SASE SNARKs to bllack-box SASE SNARKs Bag19 obtain better efficiency.

Further Work. Since our goal was to provide a simple, very general, template that allows for efficient soundness proofs, we did not fully optimize all eight new SNARKs.

Historic Remark. The second eprint version (from July 13, 2019) differs significantly from the first eprint version from May 31, 2019. The main difference is in the handling of simulation-extractability (SE): the earlier version achieved ASE but not SASE. In fact, its ASE security proofs contained a subtle error, introduced in the last moment during a submission rush. The current version of
this paper achieves SASE by using tags; this changed the SE SNARKs somewhat but their efficiency remains comparable to the SE SNARKs in the earlier version. Due to the use of tags, we stopped using the full power of the generic bilinear group model in the soundness / SE proofs and added a lengthy description of the AGM and tautological knowledge assumptions.

The third eprint version (from July 23, 2019) adds subversion-security and many typo fixes.

Acknowledgment. Helger Lipmaa was supported by the European Union's Horizon 2020 research and innovation programme under grant agreement No 780477 (project PRIViLEDGE), and by the Estonian Research Council grant (PRG49).

## A Formal Security Definitions

## A. 1 Zero-Knowledge

As in Gro16, we define all security notions against a non-uniform adversary. However, since our security reductions are uniform, it is a simple matter to consider only uniform adversaries, as it was done by Bellare et al. [BFS16] (see also Gol93).

Definition 2 (Perfect Completeness). A non-interactive argument $\Psi$ is perfectly complete for $\mathcal{R}$, if for all $\lambda$, all $\left(\mathbf{R}\right.$, aux $\left._{\mathbf{R}}\right) \in \operatorname{range}\left(\mathcal{R}\left(1^{\lambda}\right)\right)$, $\operatorname{tag} \tau \in$ Tags, and $(\mathrm{x}, \mathrm{inp}) \in \mathbf{R}$,

$$
\operatorname{Pr}\left[\begin{array}{l}
(\mathrm{crs}, \mathrm{td}) \leftarrow \mathrm{K}_{\mathrm{crs}}\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}\right): \\
\mathrm{V}\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}, \operatorname{crs}_{\mathrm{V}}, \tau, \mathrm{x}, \mathrm{P}\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}, \operatorname{crs}_{\mathrm{P}}, \tau, \mathrm{x}, \mathrm{inp}\right)\right)=1
\end{array}\right]=1 .
$$

Definition 3 (Computational Knowledge-Soundness). $\Psi$ is computationally (adaptively) knowledge-sound for $\mathcal{R}$, if for every non-uniform PPT $\mathcal{A}$, there exists a non-uniform PPT extractor $\operatorname{Ext}_{\mathcal{A}}$, s.t. for all $\lambda, \operatorname{Adv}_{\mathcal{R}, \mathcal{A}}^{\text {snd }}(\lambda):=$

$$
\operatorname{Pr}\left[\begin{array}{l}
\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}\right) \leftarrow \mathcal{R}\left(1^{\lambda}\right) ;(\mathrm{crs}, \mathrm{td}) \leftarrow \mathrm{K}_{\mathrm{crs}}\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}\right) ; r \leftarrow_{r} \operatorname{RND}(\mathcal{A}) ; \\
(\tau, \mathrm{x}, \pi) \leftarrow \mathcal{A}\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}, \mathrm{crs} ; r\right) ; \operatorname{inp} \leftarrow \operatorname{Ext}_{\mathcal{A}}\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}, \mathrm{crs} ; r\right): \\
(\mathrm{x}, \mathrm{inp}) \notin \mathbf{R} \wedge \mathrm{V}\left(\mathbf{R}, \mathrm{aux}_{\mathbf{R}}, \mathrm{crsv}, \tau, \mathrm{x}, \pi\right)=1
\end{array}\right] \approx_{\lambda} 0
$$

Here, $\operatorname{aux}_{\mathbf{R}}$ can be seen as a common auxiliary input to $\mathcal{A}$ and $\mathrm{Ext}_{\mathcal{A}}$ that is generated by using a benign [BCPR14] relation generator; we recall that we just think of aux $\mathbf{R}_{\mathbf{R}}$ as being the description of a secure bilinear group. A knowledgesound argument system is called an argument of knowledge.

Definition 4 (Statistically Unbounded ZK [Gro06]). $\Psi$ is statistically unbounded Sub-ZK for $\mathcal{R}$, if for all $\lambda$, all $\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}\right) \in \operatorname{range}\left(\mathcal{R}\left(1^{\lambda}\right)\right)$, all $\tau \in$ Tags, and all computationally unbounded $\mathcal{A}, \varepsilon_{0}^{u n b} \approx_{\lambda} \varepsilon_{1}^{u n b}$, where

$$
\varepsilon_{b}^{u n b}=\operatorname{Pr}\left[(\mathrm{crs}, \mathrm{td}) \leftarrow \mathrm{K}_{\mathrm{crs}}\left(\mathbf{R}, \mathrm{aux}_{\mathbf{R}}\right): \mathcal{A}^{\mathrm{O}_{b}(\cdot, \cdot, \cdot)}\left(\mathbf{R}, \mathrm{aux}_{\mathbf{R}}, \mathrm{crs}\right)=1\right] .
$$

Here, the oracle $\mathrm{O}_{0}(\tau, \mathrm{x}, \mathrm{inp})$ returns $\perp$ (reject) if $(\mathrm{x}, \mathrm{inp}) \notin \mathbf{R}$, and otherwise it returns $\mathbf{P}\left(\mathbf{R}\right.$, aux $\left._{\mathbf{R}}, \mathrm{crsp}, \tau, \mathrm{x}, \mathrm{inp}\right)$. Similarly, $\mathrm{O}_{1}(\tau, \mathrm{x}, \mathrm{inp})$ returns $\perp$ (reject) if $(\mathrm{x}, \mathrm{inp}) \notin \mathbf{R}$, and otherwise it returns $\operatorname{Sim}\left(\mathbf{R}, \operatorname{aux}_{\mathbf{R}}, \mathrm{crs}, \mathrm{td}, \tau, \mathrm{x}\right) . \Psi$ is perfectly unbounded ZK for $\mathcal{R}$ if one requires that $\varepsilon_{0}^{u n b}=\varepsilon_{1}^{u n b}$.

## A. 2 Simulation-Extractability

ASE (any simulation-extractability) and SASE (strong any simulationextractability) guarantee knowledge-soundness even if one can obtain simulation answers to arbitrary statement, with the following difference: an ASE SNARK does not use tags and explicitly forbids simulation queries to the same statement that the adversary outputs. On the other hand, an SASE SNARK uses tags and allows to ask simulation queries even to the statement that the adversary outputs; however, it forbids to ask simulation queries for the same tag.

Fig. 6. Simulation-extractability experiments: strong any-simulation (SASE, left) and any-simulation (ASE, right). Differences are highlighted

Definition 5 (SASE SNARK [DHLW10,KW15GM17]). Let $\Pi=$ ( $\mathrm{K}_{\mathrm{cr}}, \mathrm{P}, \mathrm{V}, \mathrm{Sim}$ ) be a SNARK for relation $\mathbf{R}$. Define

$$
\operatorname{Adv}_{I I, \mathcal{A}, \mathrm{Ext}_{\mathcal{A}}}^{\text {sase }}(\lambda):=\operatorname{Pr}\left[\operatorname{Exp}_{I I, \mathcal{A}, \mathrm{Ext}_{\mathcal{A}}}^{\text {sase }}(\lambda)\right],
$$

where the experiment $\operatorname{Exp}_{\Pi, \mathcal{A}, \operatorname{Ext}_{\mathcal{A}}}^{\text {sase }}(\lambda)$ is depicted in Fig. 6. $\Pi$ is non-black-box strong any-simulation-extractable (SASE) if for any PPT adversary $\mathcal{A}$ there exists a PPT extractor $\mathrm{Ext}_{\mathcal{A}}$ such that $\operatorname{Adv}_{\Pi, \mathcal{A}, \mathrm{Ext}}^{\mathcal{A}}$ sase $(\lambda) \approx_{\lambda} 0$.

Definition 6 (ASE SNARK [DHLW10,KW15 GM17]). Let $\Pi=$ ( $\mathrm{K}_{\mathrm{cr}}, \mathrm{P}, \mathrm{V}, \mathrm{Sim}$ ) be a SNARK for relation $\mathbf{R}$. Define

$$
\operatorname{Adv}_{\Pi, \mathcal{A}, \mathrm{Ext}_{\mathcal{A}}}^{\text {ase }}(\lambda):=\operatorname{Pr}\left[\operatorname{Exp}_{\Pi, \mathcal{A}, \mathrm{Ext}}^{\mathcal{A}}, ~(\lambda)\right],
$$

where the experiment $\operatorname{Exp}_{\Pi, \mathcal{A}, \mathrm{Ext}_{\mathcal{A}}}^{\text {ase }}(\lambda)$ is depicted in Fig. $\sigma$. $\Pi$ is non-black-box any-simulation-extractable (ASE) if for any PPT adversary $\mathcal{A}$ there exists a $P P T$ extractor $\mathrm{Ext}_{\mathcal{A}}$ such that $\operatorname{Adv}_{I, \mathcal{A}, \mathrm{Ext}_{\mathcal{A}}}^{\text {ase }}(\lambda) \approx_{\lambda} 0$.

## B Discussion: Verification Equation with One Pairing

Consider the case the verification equation $V$ consists of only one pairing evaluation. That is,

$$
V^{*}\left(X, \boldsymbol{Q}_{1}, \boldsymbol{Q}_{2}\right)=\left(f_{1}(X)+\sum_{k} c_{1 k} Q_{1 k}\right)\left(f_{2}(X)+\sum_{k} c_{2 k} Q_{2 k}\right)
$$

for polynomials $f_{1}(X)$ and $f_{2}(X)$ and coefficients $c_{\iota k}$. (As in the knowledgesoundness proof of Theorem 1, $Y$ is not an indeterminate.) In this case, under a

PDL assumption, the creation of new random group elements - independently of their distribution - does not help the adversary at all.

Really, $V^{*}\left(x, \boldsymbol{q}_{1}, \boldsymbol{q}_{2}\right)=0$ is only possible if $\sum c_{\iota k} q_{\iota k}=-f_{\iota}(x)$ for at least one $\iota$. W.l.o.g., assume it holds for $\iota=1$. This means that $\left[q_{1 k}\right]_{1}$ (or at least their weighted sum, which is the only thing that matters) are not created as random new group elements but as evaluations of some polynomials in $x$. Thus, one can assume that the adversary created no random group elements in $\mathbb{G}_{1}$. Hence,

$$
V^{*}\left(X, \boldsymbol{Q}_{1}, \boldsymbol{Q}_{2}\right)=f_{1}(X)\left(f_{2}(X)+\sum c_{2 k} q_{2 k}\right)
$$

for some polynomials $f_{1}(X)$ and $f_{2}(X)$. Next, either $f_{1}(x)=0$ or $\sum c_{2 k} q_{2 k}=$ $-f_{2}(x)$. In the first case, $f_{1}(X) \neq 0$ (otherwise also $V^{*}\left(X, \boldsymbol{Q}_{1}, \boldsymbol{Q}_{2}\right)=0$ as a polynomial) but $f_{1}(x)=0$ and thus one has broken the $(2 n-1, n-1)$-PDL assumption. In the second case, the adversary created no random group elements in $\mathbb{G}_{1}$ and thus

$$
V^{*}\left(X, \boldsymbol{Q}_{1}, \boldsymbol{Q}_{2}\right)=f_{1}(X) f_{2}(X) .
$$

Again, since $f_{1}(x) f_{2}(x)=0$ but $f_{1}(X) f_{2}(X) \neq 0$, the adversary has broken the ( $2 n-1, n-1$ )-PDL assumption. Hence, creating new group elements does not increase the adversarial power.

[^0]:    ${ }^{4}$ See [FKL18, Section 1.2] for a less concrete analysis of the Sub-AGM case.

[^1]:    ${ }^{5}$ Since this subspace is trivial (equal to the whole space), we need to rely on a knowledge assumption to achieve security. See [FLSZ17] that used a similar technique to combine QA-NIZK and SNARKs.
