#### Abstract

In this paper, we revisit the difference enumeration techniques for LowMC and develop new algebraic techniques to achieve efficient key-recovery attacks with negligible memory complexity. Benefiting from our technique to reduce the memory complexity, we could significantly improve the attacks on LowMC when the block size is much larger than the key size and even break LowMC with such a kind of parameter. On the other hand, with our new key-recovery technique, we could significantly improve the time to retrieve the full key if given only a single pair of input and output messages together with the difference trail that they take, which was stated as an interesting question by Rechberger et al. in ToSC 2018. Combining both the techniques, with only 2 chosen plaintexts, we could break 4 rounds of LowMC adopting a full S-Box layer with block size of 129,192 and 255 bits, respectively, which are the 3 recommended parameters for Picnic3, an alternative third-round candidate in NIST's Post-Quantum Cryptography competition. We have to emphasize that our attacks do not indicate that Picnic3 is broken as the Picnic use-case is very different and an attacker cannot even freely choose 2 plaintexts to encrypt for a concrete LowMC instance. However, such parameters are deemed as secure in the latest LowMC. Moreover, much more rounds of seven instances of the backdoor cipher LowMC-M as proposed by Peyrin and Wang in CRYPTO 2020 can be broken without finding the backdoor by making full use of the allowed $2^{64}$ data. The above mentioned attacks are all achieved with negligible memory.

Keywords: LowMC, LowMC-M, linearization, key recovery, negligible memory

## 1 Introduction

LowMC [5], a family of flexible Substitution-Permutation-Network (SPN) block ciphers aiming at achieving low multiplicative complexity, is a relatively new
design in the literature and has been utilized as the underlying block cipher of the post-quantum signature scheme Picnic [3], which is an alternative thirdround candidate in NIST's Post-Quantum Cryptography competition [1]. The feature of LowMC is that users can independently choose the parameters to instantiate it, from the number of S-boxes in each round to the linear layer, key schedule function and round constants.

To achieve a low multiplicative complexity, the construction adopting a partial S-box layer (only partial state bits will pass through the S-boxes and an identity mapping is applied for the remaining state bits) together with a random dense linear layer is most used. As such a construction is relatively new, novel cryptanalysis techniques are required. Soon after its publication, the higher-order differential attack and interpolation attack on LowMC were proposed [14|12, both of which required many chosen plaintexts. To resist these attacks, LowMC v2 was proposed, i.e. new formulas were used to determine the secure number of rounds. To analyse one of the most useful settings, namely a few S-boxes in each round with low allowable data complexities, the so-called difference enumeration technique [25], which we call difference enumeration attack, was proposed, which directly made LowMC v2 move to LowMC v3. The difference enumeration attack is a chosen-plaintext attack. The basic idea is to encrypt a pair (or more) of chosen plaintexts and then recover the difference evolutions between the plaintexts through each component in each round, i.e. to recover the differential trail. Finally, the secret key is derived from the recovered differential trail. As a result, the number of the required plaintexts can be as small as 4. For simplicity, LowMC represents LowMC v3 in the remaining part of this paper.

Recently, Picnic3 [18] has been proposed and alternative parameters have been chosen for LowMC. Specifically, different from Picnic2 where a partial S-box layer is adopted when instantiating LowMC, a full S-box layer is used when generating the three instances of LowMC in Picnic3. By choosing the number of rounds as 4 , the designers found that the cost of signing time and verifying time can be reduced while the signature size is almost kept the same with that of Picnic2 [3]. By increasing the number of rounds to 5 for a larger security margin, the cost is still lower than that of Picnic2. Consequently, 4-round LowMC is recommended and 5 -round LowMC is treated as an alternative choice.

As can be found in the latest source code [2] to determine the secure number of rounds, the 3 instances of 4 -round LowMC used in Picnic3 are deemed as secure. However, there is no thorough study for the constructions adopting a full S-box layer and low allowable data complexities (as low as 2 plaintexts ${ }^{6}$ ). Therefore, it is meaningful to make an investigation in this direction. It should be mentioned that a recent guess-and-determine attack with 1 plaintext can only reach 2 rounds for the constructions with a full S-box layer [7].

[^0]Moreover, a family of tweakable block ciphers called LowMC-M [23] was proposed in CRYPTO 2020, which is built on LowMC and allows to embed a backdoor in the instantiation. It is natural to ask whether the additional available degrees of freedom of the tweak can give more power to an attacker. Based on the current cryptanalysis [14|12|25, the designers claim that all the parameters of LowMC-M are secure even if the tweak is exploitable by an attacker.

Related Techniques. The algebraic technique seems to be a prominent tool to analyze designs using low-degree S-boxes. The recent progress made in the cryptanalysis of Keccak is essentially based on algebraic techniques, including the preimage attacks [16|19], collision attacks (1124|26|15) and cube attacks [13|17|20].

A pure algebraic attack is to construct a multivariate equation system to describe the target problem and then to solve this equation system efficiently. When the equation system is linear, the well-known gaussian elimination can be directly applied. However, when the equation system is nonlinear, solving such an equation system is NP-hard even if it is quadratic. For the design of block ciphers, there may exist undesirable algebraic properties inside the design which can simplify the equation system and can be further exploitable to accelerate the solving of equations. Such an example can be found in the recent cryptanalysis of the initial version of MARVELLOUS [6] using Gröbner basis attacks [4]. Indeed, there was once a trend to analyze the security of AES against algebraic attacks 10[22]. In the literature, the simple linearization and guess-and-determine methods are also common techniques to solve a nonlinear multivariate equation system.

Recently in CRYPTO 2020, a method is proposed to automatically verify a specified differential trail [21. The core technique is to accurately capture the relations between the difference transitions and value transitions. We are inspired from such an idea and will further demonstrate that when the relations between the two transitions are special and when the difference transitions are special, under the difference enumeration attack framework [25], it is possible to utilize algebraic techniques to efficiently recover the differential trail for a single pair of (plaintext, ciphertext) and then to efficiently retrieve the full key from the recovered differential trail.

Our Contributions. This work is based on the difference enumeration attack framework and we developed several non-trivial techniques to significantly improve the cryptanalysis of LowMC. Our results are detailed as follows:

1. We developed an algebraic technique to reduce the memory complexity to recover the unknown differential trails, which allows us to break one parameter of LowMC where the block size is much larger than the key size and to significantly improve the key-recovery attacks on LowMC.
2. By studying the S-box of LowMC, we developed an efficient algebraic technique to retrieve the full key if given only a single pair of (plaintext, ciphertext) along with the corresponding differential trail that they take, which was stated as an interesting question by Rechberger et al. in ToSC 2018.
3. We further developed a new difference enumeration attack framework to analyze the constructions adopting a full S-box layer and low allowable data complexities.
4. Combining our techniques, we could break the 3 recommended parameters of 4-round LowMC used in Picnic3, which are treated as secure against the existing cryptanalysis techniques, though it cannot lead to an attack on Picnic3. In addition, much more rounds of 7 instances of LowMC-M can be broken without finding the backdoor, thus violating the security claim of the designers.

All our key-recovery attacks on LowMC only require 2 chosen plaintexts and negligible memory. For the attacks on LowMC-M, we will make full use of the allowed data to achieve more rounds. More details are displayed in Table 1, Table 2 and Table 3. To advance the understanding of the secure number of rounds for both LowMC and LowMC-M, we focus on the attacks reaching the largest number of rounds with the complexity below the exhaustive search.

Organization. A brief introduction of LowMC and LowMC-M is given in section 2. We then revisit the difference enumeration attack framework in Section 3. In Section 4, we make a study on the S-box of LowMC. The techniques to reduce the memory complexity and to reduce the cost to retrieve the secret key from a differential trail are detailed in Section 5 and Section 6 respectively. The application of the two techniques to LowMC with a partial S-box layer and LowMC-M can be referred to Section 7 The attack on LowMC with a full S-box layer is explained in Section 8. The experimental results are reported in Section 9. Finally, we conclude the paper in Section 10.

## 2 Preliminaries

### 2.1 Notation

As there are many parameters for both LowMC [5] and LowMC-M [23], we use $n, k, m$ and $R$ to represent the block size in bits, the key size in bits, the number of S-boxes in each round and the total number of rounds, respectively. Besides, the number of allowed data under each key is denoted by $2^{D}$. In addition, the following notations will also be used:

1. $\operatorname{Pr}[\omega]$ represents the probability that the event $\omega$ happens.
2. $\operatorname{Pr}[\omega \mid \chi]$ represents the conditional probability, i.e. the probability that $\omega$ happens under the condition that $\chi$ happens.
3. $x \gg y$ represents that $x$ is much larger than $y$.

### 2.2 Description of LowMC

LowMC [5] is family of SPN block ciphers proposed by Albrecht et al. in Eurocrypt 2015. Different from conventional block ciphers, the instantiation
of LowMC is not fixed and each user can independently choose parameters to instantiate LowMC.

LowMC follows a common encryption procedure as most block ciphers. Specifically, it starts with a key whitening (WK) and then iterates a round function by $R$ times. The round function at the $(i+1)$-th $(0 \leq i \leq R-1)$ round can be described as follows:

1. SBoxLayer (SB): A 3-bit S-box $S\left(x_{0}, x_{1}, x_{2}\right)=\left(x_{0} \oplus x_{1} x_{2}, x_{0} \oplus x_{1} \oplus x_{0} x_{2}, x_{0} \oplus\right.$ $\left.x_{1} \oplus x_{2} \oplus x_{0} x_{1}\right)$ will be applied to the first $3 m$ bits of the state in parallel, while an identity mapping is applied to the remaining $n-3 m$ bits.
2. MatrixMul (L): A regular matrix $L_{i} \in \mathbb{F}_{2}^{n \times n}$ is randomly generated and the $n$-bit state is multiplied with $L_{i}$.
3. ConstantAddition ( $\mathbf{A C}$ ): An $n$-bit constant $C_{i} \in \mathbb{F}_{2}^{n}$ is randomly generated and is XORed to the $n$-bit state.
4. KeyAddition (AK): A full-rank $n \times k$ binary matrix $M_{i+1}$ is randomly generated. The $n$-bit round key $K_{i+1}$ is obtained by multiplying the $k$-bit master key with $M_{i+1}$. Then, the $n$-bit state is XORed with $K_{i+1}$.

The whitening key is denoted by $K_{0}$ and it is also calculated by multiplying the master key with a random $n \times k$ binary matrix $M_{0}$.

It has been studied that there is an equivalent representation of LowMC by placing (AK) between ( $\mathbf{S B}$ ) and ( $\mathbf{L}$ ). In this way, the size of the round key $K_{i}(i>0)$ becomes $3 m$, which is still linear in the $k$-bit master key and can be viewed as multiplying the master key with a $3 m \times k$ random binary matrix. Notice that $K_{0}$ is still an $n$-bit value. We will use this equivalent representation throughout this paper for simplicity.

Moreover, for convenience, we denote the plaintext by $p$ and the ciphertext by $c$. The state after $\mathbf{W K}$ is denoted by $A_{0}$. In the $(i+1)$-th round, the input state of $\mathbf{S B}$ is denoted by $A_{i}$ and the output state of $\mathbf{S B}$ is denoted by $A_{i}^{S}$, as shown below:

$$
p \xrightarrow{\mathbf{W K}} A_{0} \xrightarrow{\mathbf{S B}} A_{0}^{S} \xrightarrow{\mathbf{A K}} \xrightarrow{\mathbf{L}} \xrightarrow{\mathbf{A C}} A_{1} \rightarrow \cdots \rightarrow A_{R-1} \xrightarrow{\mathbf{S B}} A_{R-1}^{S} \xrightarrow{\mathbf{A K}} \xrightarrow{\mathbf{L}} A_{R} .
$$

In addition, we also introduce the notations to represent the xor difference transitions, as specified below:

$$
\Delta_{p} \xrightarrow{\mathrm{WK}} \Delta_{0} \xrightarrow{\mathrm{SB}} \Delta_{0}^{S} \xrightarrow{\mathrm{AK}} \xrightarrow{\mathrm{~L}} \Delta_{1}^{\mathrm{AC}} \rightarrow \cdots \rightarrow \Delta_{R-1} \xrightarrow{\mathrm{SB}} \Delta_{R-1}^{S} \xrightarrow{\mathrm{AK}} \xrightarrow{\mathrm{~L}} \Delta_{R} .
$$

Specifically, in the $(i+1)$-th round, the difference of the input state of $\mathbf{S B}$ is denoted by $\Delta_{i}$ and the difference of the output state of $\mathbf{S B}$ is denoted by $\Delta_{i}^{S}$. The difference of plaintexts is denoted by $\Delta_{p}$, i.e. $\Delta_{p}=\Delta_{0}$.

Definition 1. A differential trail $\Delta_{0} \rightarrow \Delta_{i+1} \rightarrow \cdots \rightarrow \Delta_{r}$ is called a r-round compact differential trail when all $\left(\Delta_{j}, \Delta_{j}^{S}\right)(0 \leq j \leq r-1)$ and $\Delta_{r}$ are known.

LowMC-M [23] is a family of tweakable block ciphers built on LowMC, which was introduced by Peyrin and Wang in CRYPTO 2020. The feature of LowMC-M is that backdoors can be inserted in the instantiation. The only
difference between LowMC and LowMC-M is that there is an addition operation AddSubTweak (AT) after AK and WK where the sub-tweaks are the output of an extendable-output-function (XOF) function by setting the tweak as the input. A detailed description can be referred to Appendix A

## 3 The Difference Enumeration Techniques

In this section, we briefly revisit the difference enumeration techniques in [25]. The overall procedure can be divided into three phases, as depicted in Figure 1 .

Phase 1: Determine an input difference $\Delta_{0}$ such that it will not activate any S-boxes in the first $t_{0}$ rounds, i.e. $\operatorname{Pr}\left[\Delta_{0} \rightarrow \Delta_{t_{0}}\right]=1$.
Phase 2: Compute the corresponding $\Delta_{t_{0}}$ from $\Delta_{0}$ obtained at Phase 1. Then, enumerate the differences forwards for $t_{1}$ consecutive rounds and collect all reachable values for $\Delta_{t_{0}+t_{1}}$. Store all possible values of $\Delta_{t_{0}+t_{1}}$ in a table denoted by $D_{f}$.
Phase 3: Encrypt a pair of plaintexts whose difference equals $\Delta_{0}$ and compute the difference $\Delta_{r}$ of the corresponding two ciphertexts. Enumerate all reachable differences of $\Delta_{t_{0}+t_{1}}$ backwards for $t_{2}$ rounds staring from $\Delta_{r}$ and check whether it is in $D_{f}$.

Fig. 1: The framework of the difference enumeration techniques

For convenience, suppose the reachable differences of $\Delta_{t_{0}+t_{1}}$ obtained by computing backwards are stored in a table denoted by $D_{b}$, though there is no need to store them. To construct a distinguisher, one should expect that $\left|D_{f}\right| \times\left|D_{b}\right|<2^{n}$. In this way, one could only expect at most one solution that can connect the difference transitions in both directions. Since there must be a solution, the solution found with the above difference enumeration techniques is the actual solution. After the compact differential trail is determined, i.e. the difference transitions in each round are fully recovered, the attacker launches the key-recovery phase.

To increase the number of rounds that can be attacked, the authors exploited the concept of $d$-difference [27], which can increase the upper bound for $\left|D_{f}\right| \times$ $\left|D_{b}\right|$, i.e. $\left|D_{f}\right| \times\left|D_{b}\right|<\min \left(2^{k}, 2^{n d}\right)$. It should be noted that $\left|D_{f}\right|=\lambda_{d}^{m t_{1}}$
and $\left|D_{b}\right|=\lambda_{d}^{m t_{2}}$, where $\lambda_{d}$ denotes the average number of reachable output $d$-differences over the $S$-box for a uniformly randomly chosen input $d$-difference. For the 3 -bit S-box used in LowMC, $\lambda_{1} \approx 3.62 \approx 2^{1.86}$ and $\lambda_{2} \approx 6.58 \approx 2^{2.719}$. Therefore, a larger number of rounds can be covered with $d$-differences $(d>1)$ when $k \geq n$. As for $n>k$, it is thus more effective to use the standard difference $(d=1)$ rather than the $d$-difference $(d>1)$. This paper is irrelevant to the concept of $d$-difference [27] and hence we omit the corresponding explanation.

It is claimed in [25] that to efficiently recover the secret key based on the recovered compact differential trail, a few pairs of plaintexts are required to identify the unique secret key. As our key-recovery technique is quite different, we refer the interested readers to 25 for details.

### 3.1 The Extended Framework

It is stated in [25] that the above framework can be extended to more rounds if the allowed data are increased. Indeed, as can be found in the latest reference code [2] of LowMC (LowMC v3), the designers have already taken several extensions of the framework in [25] into account to determine a secure number of rounds with the parameter $(n, k, D, m)$. The extended framework is depicted in Figure 2. On the whole, the procedure can be divided into the following five

Fig. 2: The extended framework of the difference enumeration techniques
phases:
Phase 1: Iterate all possible $d$ satisfying $1 \leq d \leq(2 k / n+1)$ and $\log _{2}(d+1) \leq D$. For each valid $d$, compute $r_{0}+r_{1}+r_{2}+r_{3}$ as follows and choose its maximal value as the secure number of rounds against the difference enumeration attacks.
Phase 2: Determine the maximal value of $r_{0}$ such that one could always construct a probability-1 $d$-differential trail in the first $r_{0}$ rounds.
Phase 3: Determine the maximal value of $r_{1}$ such that $\lambda_{d}^{m r_{1}}<\min \left(2^{k}, 2^{n d}\right)$.
Phase 4: Determine the maximal value of $r_{2}$ such that $\lambda_{d}^{m r_{2}}<\min \left(2^{k}, 2^{n d}\right)$.
Phase 5: Determine the maximal value of $r_{3}$ such that one could always construct a probability-1 $d$-differential trail in the last $r_{3}$ rounds with the allowed number of data.

For convenience, let $D_{f}$ and $D_{b}$ still denote the set of reachable $d$-differences of $\Delta_{r_{0}+r_{1}}$ backwards and forwards, respectively. Compared with the framework introduced in [25], there are three different points in the extended framework.
Point 1: $\left|D_{f}\right|$ is much larger when considering the standard difference for $n=k$. Point 2: $\left|D_{b}\right|$ is much larger when considering the standard difference for $n=k$. Point 3: There are extra $r_{3}$ rounds where the difference transitions can be determined by using the available plaintexts.
Specifically, when considering the standard difference for $n=k$, there is a constraint that $\left|D_{f}\right| \times\left|D_{b}\right|<2^{n}$ in the original framework [25]. However, the constraint becomes $\left|D_{f}\right|<2^{n}$ and $\left|D_{b}\right|<2^{n}$ in the extended framework, thus significantly increasing the value of $r_{1}+r_{2}$. In addition, after choosing a good starting input $d$-difference in the plaintexts, the attacker could construct $\left\lfloor\frac{2^{D}}{d+1}\right\rfloor$ different tuples of plaintexts satisfying the chosen input $d$-difference. For each tuple of plaintexts, the attacker can obtain the corresponding $d$-difference in the ciphertexts and check whether it will activate the S-boxes in the last $r_{3}$ rounds.

It is not difficult to derive from the above explanation that the secure number of rounds is determined by only considering the standard difference for $n=k$. However, there will be about $\lambda_{1}^{m\left(r_{1}+r_{2}\right)} \times 2^{-n}$ possible solutions for the compact differential trails. When $r_{1}+r_{2}$ takes the maximal value, $\lambda_{1}^{m\left(r_{1}+r_{2}\right)} \times 2^{-n}$ is only slightly smaller than $2^{n}$. However, costs for recovering the key which can conform one compact differential trail is relatively high. Based on the method mentioned in [25], without the aid of additional pairs of plaintexts, the cost to retrieve the full key is lower bounded by $2^{k / 3}$ as each non-zero difference transition through the 3 -bit S-box will suggest two solutions and the master key is a $k$-bit value. The reason why it is a lower bound is that there may exist inactive S-boxes in the differential trails and the attacker has to try all the 8 values. Thus, an efficient method to retrieve the full key will allow us to enlarge $\lambda_{1}^{m\left(r_{1}+r_{2}\right)} \times 2^{-n}$, thus increasing the number of rounds that can be attacked.

Apart from the high cost of key recovery, it seems to be inevitable that the attacker needs to store $D_{f}$ in advance for efficient checking. In other words, the memory complexity is rather high as $\left|D_{f}\right|=\lambda_{1}^{m r_{1}}$. We believe that attacks with negligible memory are more effective and meaningful if compared with a pure exhaustive key search.

## 4 Observations on the S-box

Before introducing our linearization-based techniques for LowMC, it is necessary to describe our observations on the 3 -bit S-box used in LowMC. Denote the 3-bit input and output of the S-box by $\left(x_{0}, x_{1}, x_{2}\right)$ and $\left(z_{0}, z_{1}, z_{2}\right)$, respectively. Based on the definition of the S-box, the following relations hold:

$$
z_{0}=x_{0} \oplus x_{1} x_{2}, z_{1}=x_{0} \oplus x_{1} \oplus x_{0} x_{2}, z_{2}=x_{0} \oplus x_{1} \oplus x_{2} \oplus x_{0} x_{1}
$$

Therefore, for the inverse of the S-box, there will exist

$$
x_{0}=z_{0} \oplus z_{1} \oplus z_{1} z_{2}, x_{1}=z_{1} \oplus z_{0} z_{2}, x_{2}=z_{0} \oplus z_{1} \oplus z_{2} \oplus z_{0} z_{1}
$$

According to the specification of the 3-bit S-box, we observed the following useful properties of the S-box.

Observation 1 For each valid non-zero difference transition $\left(\Delta x_{0}, \Delta x_{1}, \Delta x_{2}\right) \rightarrow$ $\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right)$, the inputs conforming such a difference transition will form an affine space of dimension 1. In addition, $\left(z_{0}, z_{1}, z_{2}\right)$ becomes linear in $\left(x_{0}, x_{1}, x_{2}\right)$, i.e. the $S$-box is freely linearized for a valid non-zero difference transition.

Observation 2 For each valid non-zero difference transition $\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right) \rightarrow$ $\left(\Delta x_{0}, \Delta x_{1}, \Delta x_{2}\right)$, the inputs conforming such a difference transition will form an affine space of dimension 1. In addition, $\left(x_{0}, x_{1}, x_{2}\right)$ becomes linear in $\left(z_{0}, z_{1}, z_{2}\right)$, i.e. the inverse of the $S$-box is freely linearized for a valid non-zero difference transition.

Observation 3 For each non-zero input difference $\left(\Delta x_{0}, \Delta x_{1}, \Delta x_{2}\right)$, its valid output differences form an affine space of dimension 2.

Observation 4 For each non-zero output difference $\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right)$, its valid input differences form an affine space of dimension 2.

Observation 5 For an inactive $S$-box, the input becomes linear in the output after guessing two output bits. If guessing two input bits, the output also becomes linear in the input. The same property holds for its inverse.

The last observation is trivial and let us make a short explanation for the remaining observations. For example, when $\left(\Delta x_{0}, \Delta x_{1}, \Delta x_{2}\right)=(0,0,1)$ and $\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right)=(0,0,1)$, it can be derived that $x_{0}=0$ and $x_{1}=0$. Therefore, the expressions of $\left(z_{0}, z_{1}, z_{2}\right)$ become $z_{0}=0, z_{1}=0$ and $z_{2}=x_{2}$. When the input difference is $(0,1,1)$, the corresponding valid output differences satisfy $\Delta z_{1} \oplus \Delta z_{2}=1$. When the output difference is $(0,1,1)$, the corresponding valid input differences satisfy $\Delta x_{1} \oplus \Delta x_{2}=1$. A full list of all the valid non-zero difference transitions along with the corresponding conditions on $\left(x_{0}, x_{1}, x_{2}\right)$ as well as the updated expressions for $\left(z_{0}, z_{1}, z_{2}\right)$ is given in Table 4 in App. D .

Generalization. It is easy to identify Observation 1 and Observation 2 since it is a 2-uniform 3-bit S-box. However, it is surprising that such two properties have never been exploited in the cryptanalysis of LowMC. To generalise our results, we prove that the above 5 observations hold for all 3-bit almost perfect nonlinear (APN) S-boxes. Observation 5 is trivial and we only focus on the remaining 4 observations, especially on Observation 3 and Observation 4 .

To save space, we simply explain what a 3 -bit APN S-box is. For simplicity, we still denote the input and output of the S-box by $\left(x_{0}, x_{1}, x_{2}\right)$ and $\left(z_{0}, z_{1}, z_{2}\right)=$ $S^{\prime}\left(x_{0}, x_{1}, x_{2}\right)$, respectively. Formally, for a 3 -bit APN S-box, for any valid nonzero difference transition $\left(\Delta x_{0}, \Delta x_{1}, \Delta x_{2}\right) \rightarrow\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right)$, there are only 2 solutions of $\left(x_{0}, x_{1}, x_{2}\right)$ to the following equation:

$$
S^{\prime}\left(x_{0} \oplus \Delta x_{0}, x_{1} \oplus \Delta x_{1}, x_{2} \oplus \Delta x_{2}\right)=\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right)
$$

For a 3-bit APN S-box, its algebraic degree must be 2. Hence, the S-box can be defined in the following way:

$$
\begin{aligned}
& z_{0}=\varphi_{0}\left(x_{0}, x_{1}, x_{2}\right) \oplus \kappa_{0} x_{0} x_{1} \oplus \kappa_{1} x_{0} x_{2} \oplus \kappa_{2} x_{1} x_{2} \oplus \epsilon_{0}, \\
& z_{1}=\varphi_{1}\left(x_{0}, x_{1}, x_{2}\right) \oplus \kappa_{3} x_{0} x_{1} \oplus \kappa_{4} x_{0} x_{2} \oplus \kappa_{5} x_{1} x_{2} \oplus \epsilon_{1}, \\
& z_{2}=\varphi_{2}\left(x_{0}, x_{1}, x_{2}\right) \oplus \kappa_{6} x_{0} x_{1} \oplus \kappa_{7} x_{0} x_{2} \oplus \kappa_{8} x_{1} x_{2} \oplus \epsilon_{2},
\end{aligned}
$$

where $\varphi_{i}\left(x_{0}, x_{1}, x_{2}\right)(0 \leq i \leq 2)$ are linear boolean functions and $\kappa_{j} \in \mathbb{F}_{2}$ $(0 \leq j \leq 8), \epsilon_{i} \in \mathbb{F}_{2}(0 \leq i \leq 2)$. For a specific 3 -bit APN S-box, all $\varphi_{i}\left(x_{0}, x_{1}, x_{2}\right)$, $\kappa_{j}$ and $\epsilon_{i}$ will be fixed.

First, consider the case when $\left(\Delta x_{0}, \Delta x_{1}, \Delta x_{2}\right)=(0,0,1)$. It can be found that there are four assignments to $\left(x_{0}, x_{1}\right)$ that will influence the output difference, as shown below, where $\Delta \varphi_{i}(0 \leq i \leq 2)$ represents the xor difference of the outputs of the linear function $\varphi_{i}\left(x_{0}, x_{1}, x_{2}\right)$.

$$
\begin{aligned}
\left(x_{0}, x_{1}\right) & \rightarrow\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right) \\
(0,0) & \rightarrow\left(\Delta \varphi_{0}, \Delta \varphi_{1}, \Delta \varphi_{2}\right) \\
(0,1) & \rightarrow\left(\Delta \varphi_{0} \oplus \kappa_{2}, \Delta \varphi_{1} \oplus \kappa_{5}, \Delta \varphi_{2} \oplus \kappa_{8}\right) \\
(1,0) & \rightarrow\left(\Delta \varphi_{0} \oplus \kappa_{1}, \Delta \varphi_{1} \oplus \kappa_{4}, \Delta \varphi_{2} \oplus \kappa_{7}\right) \\
(1,1) & \rightarrow\left(\Delta \varphi_{0} \oplus \kappa_{1} \oplus \kappa_{2}, \Delta \varphi_{1} \oplus \kappa_{4} \oplus \kappa_{5}, \Delta \varphi_{2} \oplus \kappa_{7} \oplus \kappa_{8}\right) .
\end{aligned}
$$

As the S-box is APN, the above four possible values of the output difference $\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right)$ are the actual 4 distinct output differences for the input difference $\left(\Delta x_{0}, \Delta x_{1}, \Delta x_{2}\right)=(0,0,1)$. As the set

$$
\left\{(0,0,0),\left(\kappa_{2}, \kappa_{5}, \kappa_{8}\right),\left(\kappa_{1}, \kappa_{4}, \kappa_{7}\right),\left(\kappa_{1} \oplus \kappa_{2}, \kappa_{4} \oplus \kappa_{5}, \kappa_{7} \oplus \kappa_{8}\right)\right\}
$$

forms a linear subspace of dimension 2 over $\mathbb{F}_{2}^{3}$, the 4 possible output differences for the input difference $(0,0,1)$ form an affine subspace of dimension 2. For each of the 4 valid difference transitions, there will be 2 linear conditions on the input bits and hence the S-box is always freely linearized, i.e. each output bit can be written as a linear expression in the input bits. Due to the symmetry of the expressions, the same holds for the input differences $(1,0,0)$ and $(0,1,0)$.

When $\left(\Delta x_{0}, \Delta x_{1}, \Delta x_{2}\right)=(0,1,1)$, we can write the accurate 4 distinct output differences in a similar way, as listed below:

$$
\begin{aligned}
\left(x_{0}, x_{1} \oplus x_{2}\right) & \rightarrow\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right) \\
(0,0) & \rightarrow\left(\Delta \varphi_{0} \oplus \kappa_{2}, \Delta \varphi_{1} \oplus \kappa_{5}, \Delta \varphi_{2} \oplus \kappa_{8}\right) \\
(0,1) & \rightarrow\left(\Delta \varphi_{0}, \Delta \varphi_{1}, \Delta \varphi_{2}\right) \\
(1,0) & \rightarrow\left(\Delta \varphi_{0} \oplus \kappa_{0} \oplus \kappa_{1} \oplus \kappa_{2}, \Delta \varphi_{1} \oplus \kappa_{3} \oplus \kappa_{4} \oplus \kappa_{5}, \Delta \varphi_{2} \oplus \kappa_{6} \oplus \kappa_{7} \oplus \kappa_{8}\right) \\
(1,1) & \rightarrow\left(\Delta \varphi_{0} \oplus \kappa_{0} \oplus \kappa_{1}, \Delta \varphi_{1} \oplus \kappa_{3} \oplus \kappa_{4}, \Delta \varphi_{2} \oplus \kappa_{6} \oplus \kappa_{7}\right) .
\end{aligned}
$$

Therefore, for each valid difference transition, there are 2 linear conditions on the input bits and the S-box is freely linearized. In addition, it can be found that the set

$$
\left\{(0,0,0),\left(\kappa_{2}, \kappa_{5}, \kappa_{8}\right)\right.
$$

$$
\left.\left(\kappa_{0} \oplus \kappa_{1}, \kappa_{3} \oplus \kappa_{4}, \kappa_{6} \oplus \kappa_{7}\right),\left(\kappa_{0} \oplus \kappa_{1} \oplus \kappa_{2}, \kappa_{3} \oplus \kappa_{4} \oplus \kappa_{5}, \kappa_{6} \oplus \kappa_{7} \oplus \kappa_{8}\right)\right\}
$$

forms a linear subspace of dimension 2 over $\mathbb{F}_{2}^{3}$, thus resulting in the fact that the 4 output differences form an affine subspace of dimension 2 . Due to the symmetry, the same conclusion also holds for the input differences $(1,1,0)$ and (1, 0, 1).

When $\left(\Delta x_{0}, \Delta x_{1}, \Delta x_{2}\right)=(1,1,1)$, the 4 distinct output differences can be written as follows:

$$
\begin{aligned}
\left(x_{0} \oplus x_{1}, x_{1} \oplus x_{2}\right) & \rightarrow\left(\Delta z_{0}, \Delta z_{1}, \Delta z_{2}\right) \\
(0,0) & \rightarrow\left(\varphi_{0} \oplus \kappa_{0} \oplus \kappa_{1} \oplus \kappa_{2}, \varphi_{1} \oplus \kappa_{3} \oplus \kappa_{4} \oplus \kappa_{5}, \varphi_{2} \oplus \kappa_{6} \oplus \kappa_{7} \oplus \kappa_{8}\right), \\
(0,1) & \rightarrow\left(\varphi_{0} \oplus \kappa_{0}, \varphi_{1} \oplus \kappa_{3}, \varphi_{2} \oplus \kappa_{6}\right) \\
(1,0) & \rightarrow\left(\varphi_{0} \oplus \kappa_{2}, \varphi_{1} \oplus \kappa_{5}, \varphi_{2} \oplus \kappa_{8}\right) \\
(1,1) & \rightarrow\left(\varphi_{0} \oplus \kappa_{1}, \varphi_{1} \oplus \kappa_{4}, \varphi_{2} \oplus \kappa_{7}\right) .
\end{aligned}
$$

Therefore, for each valid difference transition, there are 2 linear conditions on the input bits and the S-box is freely linearized. Moreover, since the set

$$
\begin{aligned}
& \left\{(0,0,0),\left(\kappa_{1} \oplus \kappa_{2}, \kappa_{4} \oplus \kappa_{5}, \kappa_{7} \oplus \kappa_{8}\right),\right. \\
& \left.\left(\kappa_{0} \oplus \kappa_{1}, \kappa_{3} \oplus \kappa_{4}, \kappa_{6} \oplus \kappa_{7}\right),\left(\kappa_{0} \oplus \kappa_{2}, \kappa_{3} \oplus \kappa_{5}, \kappa_{6} \oplus \kappa_{8}\right)\right\}
\end{aligned}
$$

forms a linear subspace of dimension 2 over $\mathbb{F}_{2}^{3}$, the 4 distinct output differences must also form an affine subspace of dimension 2.

Combining all the above cases, Observation 1 and Observation 3 hold for all 3-bit APN S-boxes. As the inverse of an APN S-box is also APN, Observation 2 and Observation 4 also hold for all 3-bit APN S-box, thus completing the proof.

## 5 Reducing the Memory Complexity

As mentioned in the previous section, it seems to be inevitable to use a sufficiently large amount of memory to store some reachable differences to achieve efficient checking for the reachable differences computed backwards. It is commonly believed that attacks requiring too much memory indeed cannot compete with a pure exhaustive key search. Therefore, we aim to significantly reduce the memory complexity in both the original and extended frameworks. Specifically, for each reachable difference computed backwards, we try to construct an equation system whose solutions can correspond to the difference transitions in the forward direction.

As illustrated in Figure 3, after we determine the differential trail in the first $r_{0}$ rounds, $\Delta_{r_{0}}$ is known and there should be at least one active S-box when taking two inputs with $\Delta_{r_{0}}$ as difference to the $\left(r_{0}+1\right)$-th round, otherwise we could extend the deterministic differential trail for one more round.

Let us introduce $3 m$ variables $\left(d_{0}, \cdots, d_{3 m-1}\right)$ to denote the output difference of the $m$ S-boxes for the input difference $\Delta_{r_{0}}$. Then, there will be at least $m$ linear relations inside $\left(d_{0}, \cdots, d_{3 m-1}\right)$. It can be found that when there is an inactive

Fig. 3: Constructing the affine subspace of reachable differences

S-box, the output difference is $(0,0,0)$, i.e. three linear relations. When there is an active S-box, the valid output differences form an affine space of dimension 2 according to Observation 3, i.e. 1 linear relation. In other words, we only need to introduce at most $3 m-m=2 m$ variables to denote the output differences for $\Delta_{r_{0}}$. For the next $l-1$ rounds, since the input difference of the S -box is uncertain due to the diffusion of a random linear layer, we directly introduce $3 m(l-1)$ variables ( $d_{3 m}, \cdots, d_{3 m l-1}$ ) to represent the output differences for each S-box. In this way, $\Delta_{r_{0}+l}$ is obviously linear in the introduced $3 m(l-1)+2 m=$ $3 m l-m=m(3 l-1)$ variables. In other words, $\Delta_{r_{0}+l}$ can be written as linear expressions in terms of the introduced $m(3 l-1)$ variables.

Then, for the difference enumeration in the backward direction, after we obtain the output difference of the S-box for $\Delta_{r_{0}+l}$, we start to construct the equation system to connect the output difference. Specifically, once the output difference of the $m$ S-boxes becomes known, it will leak at least $m$ linear relations for the input difference. Specifically, when the S-box is inactive, the input difference is 0 , i.e. three linear relations. When the S-box is active, according to Observation 4, one linear relation inside the input difference can be derived. In other words, we could collect at least $m+(n-3 m)=n-2 m$ linear equations in terms of the introduced $m(3 l-1)$ variables. When

$$
\begin{equation*}
m(3 l-1) \leq n-2 m \rightarrow n \geq m(3 l+1), \tag{1}
\end{equation*}
$$

we can expect at most one solution of the equation system. Once a solution is found, all output differences of the S-box in the middle $l$ rounds become known and we can easily check whether the difference transitions are valid by computing forwards. If the transitions are valid, a connection between the difference transitions in both directions are constructed. Otherwise, we need to consider another enumerated output difference of the S-box for $\Delta_{r_{0}+l}$ in the backward direction. We have to stress that when enumerating the differences backwards for $r_{2}$ rounds, there are indeed $l+1+r_{2}$ rounds in the middle, i.e. $r_{1}=l+1$ if following the extended framework as shown in Figure 2.

However, in some cases where $m$ is large, there is no need to make such a strong constraint as in Equation 1. Even with $n<m(3 l+1)$, at the cost of
enumerating all the solutions of the constructed linear equation system, more rounds can be covered. In this way, the time complexity to enumerate differences becomes $2^{1.86 m r_{2}+m(3 l+1)-n}$. Thus, the constraint becomes

$$
\begin{equation*}
1.86 m r_{2}+m(3 l+1)-n<k \tag{2}
\end{equation*}
$$

As $l=r_{1}-1$, it can be derived that

$$
\begin{equation*}
m\left(1.86 r_{2}+3 r_{1}-2\right)<n+k \tag{3}
\end{equation*}
$$

In addition, the following constraint on $r_{2}$ should hold as well.

$$
\begin{equation*}
1.86 m r_{2}<k \tag{4}
\end{equation*}
$$

Therefore, when $r_{1}+r_{2}$ is to be maximized, the above two inequalities should be taken into account. In this way, the time complexity of difference enumeration becomes

$$
\begin{equation*}
\max \left(2^{1.86 m r_{2}}, 2^{m\left(1.86 r_{2}+3 r_{1}-2\right)-n}\right) . \tag{5}
\end{equation*}
$$

## 6 Efficient Algebraic Techniques for Key Recovery

In this section, we describe how to retrieve the full key from a compact differential trail with an algebraic method. Following the extended framework, we assume that there is no active S -box in the last $r_{3}$ rounds. As illustrated in Figure 4, we could introduce $3 m r_{3}$ variables to represent all the input bits of the S-boxes in the last $r_{3}$ rounds. Although $A_{r}$ is the known ciphertext, the round key used in AK is unknown in the $r$-th round. Therefore, the input of the S-box is unknown in the $r$-th round and is quadratic in terms of the unknown secret key. By introducing variables $\left(v_{0}, \cdots, v_{3 m-1}\right)$ to represent the expressions of the inputs of the S-box when reversing the S-box, we could write $A_{r-1}$ as linear expressions in terms of these variables ${ }^{77}$. Similarly, it can be derived that $A_{r-r_{3}}$ can be written as linear expressions in terms of all the introduced $3 m r_{3}$ variables $\left(v_{0}, \cdots, v_{3 m r_{3}-1}\right)$.

### 6.1 Exploiting the Leaked Linear Relations

Since all the S -boxes in the last $r_{3}$ rounds are inactive, we have to introduce $3 m r_{3}$ variables to achieve linearization. However, we have not yet obtained any linear equations in terms of these variables. Therefore, we will focus on how to construct a sufficiently large number of linear equations such that there will be a unique solution of these introduced variables.

[^1]

Fig. 4: Linearizing the last $r_{3}$ rounds

It should be noticed that the difference enumeration starts from $\Delta_{r-r_{3}}$ in the backward direction. For a valid $r_{2}$-round differential propagation $\left(\Delta_{r-r_{3}} \rightarrow\right.$ $\Delta_{r-r_{3}-1} \rightarrow \cdots \rightarrow \Delta_{r-r_{3}-r_{2}}$ ) enumerated in the backward direction, there should be one valid $r_{1}$-round differential propagation $\left(\Delta_{r_{0}} \rightarrow \Delta_{r_{0}+1} \rightarrow \cdots \rightarrow \Delta_{r_{0}+r_{1}}\right)$ enumerated in the forward direction such that $\Delta_{r_{0}+r_{1}}=\Delta_{r-r_{3}-r_{2}}$. Once such a sequence is identified, i.e. $\left(\Delta_{r_{0}} \rightarrow \cdots \rightarrow \Delta_{r-r_{3}}\right)$ is fully known, we start extracting linear equations from the difference transitions inside the S-boxes in the middle $r_{1}+r_{2}$ rounds.

Specifically, for each active S-box, there will be two linear equations inside the 3 -bit output according to Observation 2. In addition, the 3 -bit S-box is freely linearized once it is active according to Observation 2, i.e. the 3-bit input can be written as linear expressions in terms of the 3-bit output. Note that $A_{r-r_{3}}$ is linear in $\left(v_{0}, \cdots, v_{3 m r_{3}-1}\right)$.

Fig. 5: Extract linear equations from the inactive S-boxes

As depicted in Figure 5, denote the equivalent round key bits used in the $\left(r-r_{3}\right)$-th round by $\left(e_{0}, \cdots, e_{3 m-1}\right)$. For simplicity, assume that all the S-boxes are active when going back $b$ rounds starting from $A_{r-r_{3}}$. The case when there are inactive S-boxes will be discussed later. Under such an assumption, we could derive $2 m$ linear equations in terms of $\left(v_{0}, \cdots, v_{3 m r_{3}-1}, e_{0}, \cdots, e_{3 m-1}\right)$ based on Observation 2, In addition, since the input becomes linear in the output for each active S-box, $A_{r-r_{3}-1}$ becomes linear in ( $v_{0}, \cdots, v_{3 m r_{3}-1}, e_{0}, \cdots, e_{3 m-1}$ ). Similarly, denote the equivalent round key bits used in the $\left(r-r_{3}-i\right)$-th round by $\left(e_{3 m i}, \cdots, e_{3 m i+3 m-1}\right)(0 \leq i \leq b-1)$. Then, one could derive $2 m$ linear equations in terms of $\left(v_{0}, \cdots, v_{3 m r_{3}-1}, e_{0}, \cdots, e_{3 m i+3 m-1}\right)$ in the $\left(r-r_{3}-i\right)$-th round and $A_{r-r_{3}-i-1}$ will be linear in $\left(v_{0}, \cdots, v_{3 m r_{3}-1}, e_{0}, \cdots, e_{3 m i+3 m-1}\right)$. Repeating such a procedure for $b$ rounds backwards, we could collect in total $2 m b$ linear equations in terms of $3 m r_{3}+3 m b$ variables $\left(v_{0}, \cdots, v_{3 m r_{3}-1}, e_{0}, \cdots, e_{3 m b-1}\right)$. Since each equivalent round key bit is linear in the $k$-bit master key according to the linear key schedule function, we indeed succeed in constructing $2 m b$ linear equations in terms of $\left(v_{0}, \cdots, v_{3 m r_{3}-1}\right)$ and the $k$-bit master key. To ensure that there is a unique solution to the equation system, the following constraint should hold:

$$
\begin{equation*}
2 m b \geq k+3 m r_{3} \tag{6}
\end{equation*}
$$

As $2 m$ linear equations will be leaked when going back 1 round, there may exist redundant linear equations, i.e. $2 m b>k+3 m r_{3}$. Indeed, only

$$
\begin{equation*}
h=\left\lceil\frac{\left(k+3 m r_{3}\right)-2 m(b-1)}{2}\right\rceil \tag{7}
\end{equation*}
$$

active S-boxes are needed in the $\left(r-r_{3}-b\right)$-th round. In this way, we only need in total

$$
\begin{equation*}
H=h+m(b-1) \tag{8}
\end{equation*}
$$

S-boxes to ensure that there exists a unique solution of the constructed equation system.

### 6.2 Linearizing the Inactive S-boxes

After discussing the case when all the S-boxes are active when going back $b$ rounds starting from $A_{r-r_{3}}$, consider the case when there are $q$ inactive S-boxes among the required $H$ S-boxes in these $b$ rounds $(0 \leq q \leq H)$. Specifically, we aim to compute the time complexity to recover the full key for such a case.

While 2 linear equations can be freely derived from the output of an active S-box and the input becomes freely linear in the output for an active S-box as explained previously, linearizing the inactive S-box will require additional cost when going backwards. For an inactive S-box, it can be linearized by guessing two bits of its input or output according to Observation 5. In other words, even for an inactive S-box, we could guess 2 linear equations for its output and then the input still becomes linear in the output. Therefore, the number of equations
remain the same as in the case when all the S-boxes are active. The only cost is that we need to iterate $2^{2 q}$ times of guessing. If Equation 6 holds, for each time of guessing, one could only expect 1 unique solution of the $k$-bit master key. Therefore, the expected time to recover the full key from one random compact differential trail can be evaluated as follows:

$$
T_{0}=\sum_{q=0}^{H}\left(\frac{7}{8}\right)^{H-q} \times\left(\frac{1}{8}\right)^{q} \times\binom{ H}{q} \times 2^{2 q}=\sum_{q=0}^{H}\left(\frac{7}{8}\right)^{H-q} \times\left(\frac{1}{2}\right)^{q} \times\binom{ H}{q}=1.375^{H},
$$

where $H=h+m(b-1)$.
The above formula shows the expected time to recover the full key from one compact differential trail. It can not be ensured that the recovered key is the actual one and one has to further verify it by checking the plaintextciphertext pair. If there are $N$ valid compact differential trails left in the extended framework, the total time complexity to recover the correct master key is therefore

$$
\begin{equation*}
T_{1}=N \times 1.375^{H}=N \times 2^{0.46 H} \tag{9}
\end{equation*}
$$

Similar to the above method, we could also give a formula to compute the expected time to recover the correct key if following the simple method as discussed in [25]. It should be noted that there is no extra strategy used in the key-recovery phase in [25] if with only 2 plaintexts. Specifically, when the S-box is active, the attacker needs to try the two possible values. When the S-box is inactive, the attacker needs to try all the 8 possible values. However, since the attacker could always derive 3-bit information of the master key from one S-box in this way, he only needs to go back $b^{\prime}=\left\lceil\frac{k-m r_{3}}{3 m}\right\rceil$ rounds and the needed number of S-boxes is $H^{\prime}=\left\lceil\frac{k}{3}\right\rceil-m r_{3}$ in these $b^{\prime}$ rounds. Thus, the expected time $T_{2}$ can be formalized as follows:

$$
\begin{aligned}
T_{2} & =N \times 8^{m r_{3}} \times \sum_{q=0}^{H^{\prime}}\left(\frac{7}{8}\right)^{H^{\prime}-q} \times\left(\frac{1}{8}\right)^{q} \times\binom{ H^{\prime}}{q} \times 8^{q} \times 2^{H^{\prime}-q} \\
& =N \times 2^{3 m r_{3}} \times \sum_{q=0}^{H^{\prime}}\left(\frac{7}{8} \times 2\right)^{H^{\prime}-q} \times\left(\frac{1}{8} \times 8\right)^{q} \times\binom{ H^{\prime}}{q} \\
& =N \times 2^{3 m r_{3}} \times\left(\frac{7}{4}+1\right)^{H^{\prime}} .
\end{aligned}
$$

To explain the significant improvement achieved by our linearization techniques to recover the master key, we make a comparison between $T_{1}$ and $T_{2}$ as shown below:

$$
\frac{T_{2}}{T_{1}}=\frac{2^{3 m r_{3}}\left(\frac{7}{4}+1\right)^{H^{\prime}}}{1.375^{H}}
$$

Since $H=\left\lceil\frac{k+3 m r_{3}}{2}\right\rceil$ and $H^{\prime}=\left\lceil\frac{k}{3}\right\rceil-m r_{3}$, we have

$$
\frac{T_{2}}{T_{1}}=\frac{2^{3 m r_{3}}\left(\frac{7}{4}+1\right)^{H^{\prime}}}{1.375^{H}} \approx \frac{2^{3 m r_{3}+1.46\left(\frac{k}{3}-m r_{3}\right)}}{2^{0.46\left(0.5 k+1.5 m r_{3}\right)}} \approx 2^{0.256 k+0.85 m r_{3}}
$$

Obviously, our new key-recovery technique is much faster if compared with the method as in [25].

### 6.3 Further Improvement

Indeed, one could further reduce the cost to retrieve the full key from a compact differential trail. Specifically, we first upper bound $b$ as in Equation 6. Then, when going back $r_{3}+b-1$ rounds from the ciphertext, there will be $2 m(b-1)$ leaked equations and the last $r_{3}+b-1$ rounds are fully linearized. Since only $k+3 m r_{3}$ equations are needed and each active S-box will leak 2 equations, we only need to use

$$
h=\left\lceil\frac{\left(k+3 m r_{3}\right)-2 m(b-1)}{2}\right\rceil
$$

active S -boxes in the $\left(r-r_{3}-b\right)$-th round.
Therefore, in the $\left(r-r_{3}-b\right)$-th round, when there are more than $h$ active S-boxes, there is no need to guess extra equations but we still need to construct the equation system. However, when there are $i(i<h)$ active S-boxes, it is necessary to guess $2 h-2 i$ extra equations. Therefore, the expected time complexity can be refined as:

$$
\begin{aligned}
T_{3} & =N \times T_{4} \times \sum_{i=0}^{h}\binom{m}{i} \times\left(\frac{7}{8}\right)^{i} \times\left(\frac{1}{8}\right)^{m-i} \times 2^{2 h-2 i} \\
& +N \times T_{4} \times \sum_{i=h+1}^{m}\binom{m}{i} \times\left(\frac{7}{8}\right)^{i} \times\left(\frac{1}{8}\right)^{m-i} \\
& \approx N \times T_{4} \times 2^{2 h} \times \sum_{i=0}^{h}\binom{m}{i} \times\left(\frac{7}{32}\right)^{i} \times\left(\frac{1}{8}\right)^{m-i} \\
& +N \times T_{4} \times\left(1-\sum_{i=0}^{h}\binom{m}{i} \times\left(\frac{7}{8}\right)^{i} \times\left(\frac{1}{8}\right)^{m-i}\right) \\
& <N \times T_{4} \times\left(1+2^{2 h} \times \sum_{i=0}^{h}\binom{m}{i} \times\left(\frac{7}{32}\right)^{i} \times\left(\frac{1}{8}\right)^{m-i}\right)
\end{aligned}
$$

where

$$
T_{4}=\sum_{q=0}^{m(b-1)}\left(\frac{7}{8}\right)^{m(b-1)-q} \times\left(\frac{1}{8}\right)^{q} \times\binom{ m(b-1)}{q} \times 2^{2 q}=2^{0.46 m(b-1)} .
$$

There is no simple approximation for $T_{3}$ and we therefore provide a loose upper bound which can be easily calculated, as specified below:
$T_{3}<N \times T_{4} \times\left(1+2^{2 h} \times \sum_{i=0}^{m}\binom{m}{i} \times\left(\frac{7}{32}\right)^{i} \times\left(\frac{1}{8}\right)^{m-i}\right)=N \times T_{4} \times\left(1+2^{2 h-1.54 m}\right)$.

Hence, in general, we can use the following formula Equation 10 to calculate the time complexity to retrieve the full key from $N$ compact differential trails.

$$
\begin{equation*}
T_{3} \approx N \times 2^{0.46 m(b-1)} \times\left(1+2^{2 h-1.54 m}\right) \tag{10}
\end{equation*}
$$

It is not surprising that one could go back more than $b+r_{3}$ rounds to obtain more leaked linear equations if $b \leq r_{1}+r_{2}$. However, the cost of linearization cannot be neglected, i.e. it is necessary to introduce more variables to represent the 3 input bits of an inactive S-box. In other words, although more linear equations can be derived, more variables are involved into the equation system. Note that we need to introduce 3 extra variables to linearize an inactive S-box and only 2 linear equations can be derived from an active S-box. For such a case, it is difficult to give a simple formula describing the expected time complexity to retrieve the full key. Thus, the formula Equation 10 can be viewed as an upper bound.

## 7 Applications

The above two algebraic techniques can be utilized to further understand the security of LowMC as well as LowMC-M. LowMC is the underlying block cipher used in Picnic, which is an alternative third-round candidate in NIST's postquantum cryptography competition. For LowMC-M, it is a family of block ciphers based on LowMC which allows to insert a backdoor.

### 7.1 Applications to LowMC with a Partial S-Box Layer

In this section, we describe how to apply our techniques to instantiations with a partial S-box layer. The results are summarized in Table 1. All these attacks only require 2 chosen plaintexts and negligible memory. For better understanding, we take the attack on the parameter $(n, k, m, D, R)=(128,128,10,1,20)$ for instance.

When $(n, k, m, D)=(128,128,10,1)$, as explained in the extended framework, $r_{3}=0$ as there are only two allowed plaintexts for each instantiation and $r_{0}=\left\lfloor\frac{128}{30}\right\rfloor=4$. According to Equation $6, b=7$. Therefore, the time complexity to retrieve the master key becomes $T_{3} \approx 2^{1.86 m\left(r_{1}+r_{2}\right)-128} \times 2^{0.46 m(b-1)}=$ $2^{18.6\left(r_{1}+r_{2}\right)-81.8}<2^{128}$ based on Equation 10 . The time complexity to enumerate differences is $\max \left(1.86 m r_{2}, m\left(1.86 r_{2}+3 r_{1}-2\right)-n\right)=\max \left(18.6 r_{2}, 18.6 r_{2}+\right.$ $\left.30 r_{1}-148\right)<2^{128}$ based on Equation 5 while $18.6 r_{2}<128$ (Equation 4) and $18.6 r_{2}+30 r_{1}<276$ (Equation 3) should hold. Therefore, we have $r_{1}+r_{2} \leq 11$, $r_{2} \leq 6,18.6 r_{2}+30 r_{1} \leq 276$. To maximize $r_{1}+r_{2}$ and minimize the total time complexity, we can choose $r_{1}=5$ and $r_{2}=6$. In this way, the time complexity to recover the master key is $2^{122.8}$ while the time complexity to enumerate differences is $\max \left(2^{111.6}, 2^{111.8}\right)=2^{111.8}$. Therefore, we could break 15 (out of 20 ) rounds of LowMC taking the parameter $(n, k, m, D)=(128,128,10,1)$ with time complexity $2^{122.8}$ and only 2 chosen plaintexts.

Remark. It is not surprising to further extend $r_{1}$ by using a huge amount of memory when $n=k$ for some parameters. However, such attacks are indeed less effective compared with a pure exhaustive search. Therefore, we omit the simple extension of how to attack more rounds using huge memory.

On the other hand, when $n \gg k$, we could significantly improve $r_{1}$ as the constraint becomes $3 r_{1}<n$ when using our efficient technique to reduce the memory complexity, while the constraint is $\lambda_{1}^{r_{1}}<\min \left(2^{n d}, 2^{k}\right)$ in the extended framework. For example, when attacking $(n, k, m, D)=(1024,128,1,1), r_{1}$ cannot reach 342 without our technique to reduce the memory complexity since $2^{1.86 r_{1}}<2^{128}$ has to be satisfied if simply enumerating the reachable differences.

Table 1: The results for LowMC with a partial S-box layer

| $n$ | $k$ | $m$ | $D$ | $R$ | $r_{0}$ | $r_{1}$ | $r_{2}$ | $r_{3}$ | $r$ | Data | Time | Memory | Success Pro. |

### 7.2 Applications to LowMC-M

The only difference between LowMC and LowMC-M is that there is an additional operation after the key addition, i.e. the sub-tweak addition. Since the subtweaks are generated with an XOF function, the attacker loses the capability to directly control the difference of sub-tweaks. However, the additional degree of freedom provided by the tweak can still be utilized to further extend $r_{0}$.

Maximizing $r_{0}$ based on [8]. A very recent work [8] shows how to compute the maximal value of $r_{0}$ with a birthday search method. In a word, one could construct a probability-1 differential trail for the first $r_{0}$ rounds with time complexity $2^{\frac{3 m r_{0}-n}{2}}$ and negligible memory in an offline phase. Therefore, $r_{0}$ should satisfy the following constraint:

$$
\begin{equation*}
\frac{3 m r_{0}-n}{2}<k \tag{11}
\end{equation*}
$$

A detailed description can be referred to Appendix B. We will use this method to maximize $r_{0}$ in our attacks.

Since the allowed data complexity is $2^{64}$ for all instances of LowMC-M, we can also construct a differential trail in the last $r_{3}$ rounds where no active

S-boxes exist with $2^{3 m r_{3}+1}$ attempts, i.e. $3 m r_{3} \leq 63$. Similar to the cryptanalysis of LowMC, we could compute ( $r_{0}, r_{1}, r_{2}, r_{3}$ ) and the corresponding total time complexity, as summarized in Table 2. It should be mentioned that LowMC-M has moved to LowMC-M v2 by taking our attacks into account.

Table 2: The results for LowMC-M

| $n$ | $k$ | $m$ | $D$ | $R$ | $r_{0}$ | $r_{1}$ | $r_{2}$ | $r_{3}$ | $r$ | Data | Time | Memory | Success Pro. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 128 | 128 | 1 | 64 | 208 | 122 | 43 | 64 | 21 | 250 | $2^{64}$ | $2^{120}$ | negligible | 1 |
| 128 | 128 | 2 | 64 | 104 | 61 | 22 | 32 | 10 | 125 | $2^{61}$ | $2^{120}$ | negligible | 1 |
| 128 | 128 | 3 | 64 | 70 | 40 | 15 | 21 | 7 | 83 | $2^{64}$ | $2^{118.18}$ | negligible | 1 |
| 128 | 128 | 10 | 64 | 23 | 12 | 5 | 6 | 2 | 25 | $2^{61}$ | $2^{118}$ | negligible | 1 |
| 256 | 256 | 1 | 64 | 384 | 253 | 86 | 136 | 21 | 496 | $2^{64}$ | $2^{252.96}$ | negligible | 1 |
| 256 | 256 | 3 | 64 | 129 | 83 | 29 | 45 | 7 | 164 | $2^{64}$ | $2^{250.1}$ | negligible | 1 |
| 256 | 256 | 20 | 64 | 21 | 12 | 5 | 6 | 1 | 24 | $2^{61}$ | $2^{232}$ | negligible | 1 |

Comparison. Compared with the differential-linear attacks [8] on LowMC-M, our attacks are always better. As we utilized the idea in [8 to find a weak tweak pair, with the same time complexity to find a weak tweak pair, $r_{0}$ is always the same in their attacks and our attacks. Then, $r_{1}$ is also almost the same in their attacks and our attacks, though sometimes we will have a slightly larger $r_{1}$ according to Equation 5. The most evident advantage of our attacks exists in $r_{2}$ and $r_{3}$. With the same data, there are extra $r_{3}$ rounds in our attacks while $r_{3}$ is always zero in differential-linear attacks [8]. For $r_{2}$, it is bounded by $1.86 m r_{2}<n$ in our attacks while it is bounded by $3 m r_{2}<n$ in [8] as $3 m$ key bits are all guessed to reverse one round. Consequently, with the same data and the same time to find a weak tweak pair, our attacks are always better than the differential-linear attacks in [8, i.e. a larger number of rounds can be attacked.

## 8 A Refined Attack Framework for the Full S-Box Layer

The above two techniques are quite general and therefore they can be applied to arbitrary instances of LowMC. However, when it comes to a full S-Box layer, we need to make extra efforts to improve the extended attack framework developed by the designers of LowMC. Specifically, it is impossible to construct a probability- 1 differential trail anymore in the first few rounds. On the other hand, the cost of difference enumeration becomes rather high as a full S-box layer is applied.

To overcome the obstacle that there is no probability-1 differential trail, we turn to consider how to choose a desirable input difference such that it will activate a small number of S -boxes as possible in the first two rounds. However, since the linear layer is randomly generated, it is difficult to provide an accurate answer. Thus, similar to the method to calculate the time complexity
to retrieve the full key, the general case is taken into account and we calculate the expectation of the number of inactive S -boxes in the first two rounds and verify it via experiments.

To reduce the cost of the difference enumeration, we will demonstrate that it is possible to reduce the problem of enumerating differences to the problem of enumerating the solutions of a linear equation system by exploiting our observations on the S-box.

### 8.1 Maximizing the Number of Inactive S-boxes

To maximize the number of inactive S -boxes in the first two rounds, we consider the case when there is only one active S-box in the first round, which can obviously reduce the total number of reachable differences after two rounds.

First, consider a simple related problem. Suppose there are two boolean vectors $\mu=\left(\mu_{0}, \mu_{1}, \mu_{2}\right) \in \mathbb{F}_{2}^{3}$ and $\gamma=\left(\gamma_{0}, \gamma_{1}, \gamma_{2}\right) \in \mathbb{F}_{2}^{3}$. For a random binary matrix $M$ of size $3 \times 3$ satisfying

$$
\gamma=M \times \mu
$$

it can be calculated that

$$
\operatorname{Pr}\left[\left(\gamma_{0}, \gamma_{1}, \gamma_{2}\right)=(0,0,0) \mid\left(\mu_{0}, \mu_{1}, \mu_{2}\right) \neq(0,0,0)\right]=2^{-3}
$$

Note that $\Delta_{1}=L_{0} \times \Delta_{0}^{S}$, where $\Delta_{1}$ and $\Delta_{0}^{S}$ are two Boolean vectors of size $n$ and $L_{0}$ is a $n \times n$ invertible binary matrix. When there is only one active S-box in the first round, we can know that there is only one non-zero triple $\left(\Delta_{0}^{S}[3 i], \Delta_{0}^{S}[3 i+1], \Delta_{0}^{S}[3 i+2]\right)\left(0 \leq i<\frac{n}{3}\right)$.

Consider a randomly generated $L_{0}$ and a fixed value of $\Delta_{0}^{S}$ with only one non-zero triple $\left(\Delta_{0}^{S}[3 i], \Delta_{0}^{S}[3 i+1], \Delta_{0}^{S}[3 i+2]\right)$. Denote the event by $\alpha$ that $\left(\Delta_{0}^{S}[3 i], \Delta_{0}^{S}[3 i+1], \Delta_{0}^{S}[3 i+2]\right) \neq(0,0,0)$. Denote by $I A$ the number of inactive S-boxes in the second round. In this way, we could calculate the conditional probability that there are $q$ inactive S-boxes under $\alpha$ happens, as specified below:

$$
\operatorname{Pr}[I A=q \mid \alpha]=\binom{\frac{n}{3}}{q} \times 2^{-3 q} \times\left(\frac{7}{8}\right)^{\frac{n}{3}-q}
$$

Since that there are 7 assignments for a non-zero triple ( $\Delta_{0}^{S}[3 i], \Delta_{0}^{S}[3 i+1], \Delta_{0}^{S}[3 i+$ 2]) and there are $\frac{n}{3}$ such triples, there are in total $7 \times \frac{n}{3}$ assignments for $\Delta_{0}^{S}$ satisfying that there is only one active S-box in the first round. Hence, we can expect to find

$$
\begin{equation*}
V(n, q)=\frac{n}{3} \times 7 \times \operatorname{Pr}[I A=q \mid \alpha] \tag{12}
\end{equation*}
$$

required assignments for $\Delta_{0}^{S}$ which can ensure $q$ inactive $S$-boxes in the second round. In other words, when $V(n, q)>1$, it is expected to find more than 1 assignments for $\Delta_{0}^{S}$ such that there are $q$ inactive S -boxes in the second round.

### 8.2 Enumerating Differences Via Solving Equations

Assuming $\Delta_{i}$ and $\Delta_{i+1}^{S}$ are fixed and known, our aim is to enumerate all the solutions for $\Delta_{i}^{S}$ such that they can reach $\Delta_{i+1}^{S}$.

First, consider the case where all the S-boxes in the $(i+1)$-th and $(i+2)$-th rounds are active. In this case, there are $4^{\frac{n}{3}}$ possible reachable differences for $\Delta_{i+1}$ and each reachable difference of $\Delta_{i+1}$ can reach $\Delta_{i+1}^{S}$ with probability $2^{-\frac{n}{3}}$ as each output difference can correspond to 4 different input differences through the 3 -bit S-box of LowMC. Thus, it is expected to find the valid $2^{\frac{n}{3}}$ solutions of $\Delta_{i+1}$ in $4^{\frac{n}{3}}$ time using the simple difference enumeration.

However, similar to our technique to reduce the memory complexity, based on Observation 3, we could introduce $2 \times \frac{n}{3}$ variables to represent the possible values of $\Delta_{i}^{S}$. In this way, $\Delta_{i+1}$ will be linear in these variables. Furthermore, based on Observation 4. there will be $\frac{n}{3}$ linear constraints on $\Delta_{i+1}$. Therefore, an equation system of size $\frac{n}{3}$ in terms of $2 \times \frac{n}{3}$ variables is constructed and each solution of the equation system will correspond to a valid connection between $\Delta_{i}$ and $\Delta_{i+1}^{S}$. Thus, we could find the valid $2^{\frac{n}{3}}$ solutions in only $2^{\frac{n}{3}}$ time.

After discussing the case where all the S-boxes are active, we consider the general case. Specifically, assume there are $w$ random pairs $\left(\Delta_{i}, \Delta_{i+1}^{S}\right)$. The expected time complexity to enumerate all the valid difference transitions $\Delta_{i} \rightarrow$ $\Delta_{i+1}^{S}$ for these $w$ random pairs using our techniques can be formalized as follows.

$$
\begin{aligned}
T_{5} & =\left(\sum_{t=0}^{\lfloor 0.5 m\rfloor}\binom{m}{t} \times\left(\frac{1}{8}\right)^{t} \times\left(\frac{7}{8}\right)^{m-t} \times \sum_{j=0}^{\lfloor 0.5 m\rfloor-t}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j} \times 2^{m-2 j-2 t}\right) w \\
& +\left(1-\sum_{t=0}^{\lfloor 0.5 m\rfloor}\binom{m}{t} \times\left(\frac{1}{8}\right)^{t} \times\left(\frac{7}{8}\right)^{m-t} \times \sum_{j=0}^{\lfloor 0.5 m\rfloor-t}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j}\right) w \\
& \approx\left(\sum_{t=0}^{\lfloor 0.5 m\rfloor}\binom{m}{t} \times\left(\frac{1}{8}\right)^{t} \times\left(\frac{7}{8}\right)^{m-t} \times \sum_{j=0}^{\lfloor 0.5 m\rfloor-t}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j} \times 2^{m-2 j-2 t}\right) w+w .
\end{aligned}
$$

Specifically, when there are $t$ and $j$ inactive S-boxes in the $(i+2)$-th round and $(i+1)$-th round, respectively, the equation system is of size $3 t+(m-t)=m+2 t$ and in terms of $2(m-j)$ variables. Thus, for the case $2(m-j)-(m+2 t)=$ $m-2 j-2 t<0 \rightarrow 2 j+2 t>m$, there is no need to enumerate the solutions and we only need to construct the equation system with time 1. However, for the case $2 j+2 t \leq m$, we need to construct the equation system as well as enumerate the $2^{m-2 j-2 t}$ solutions.

As $m>1$, a loose upper bound for $T_{5}$ can be as follows:

$$
\begin{equation*}
T_{5}<w+w \times 2^{m} \times\left(\frac{29}{32}\right)^{m} \times\left(\frac{29}{32}\right)^{m} \approx w \times 2^{0.716 m} \tag{13}
\end{equation*}
$$

A fixed random $\Delta_{i+1}^{S}$. We also feel interested in that $\Delta_{i+1}^{S}$ takes a fixed random value while $\Delta_{i}$ takes $w$ random values, which is exactly the case in our attack on 4 -round LowMC with a full S-box layer.

When there are $t \leq\lfloor 0.5 \mathrm{~m}\rfloor$ inactive S -boxes in the $(i+2)$-th round, the time complexity $T_{5}$ to enumerate all the valid difference transitions can be refined as below:

$$
\begin{aligned}
T_{5} & =\left(\sum_{j=0}^{\lfloor 0.5 m\rfloor-t}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j} \times 2^{m-2 j-2 t}\right) w \\
& +\left(1-\sum_{j=0}^{\lfloor 0.5 m\rfloor-t}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j}\right) w \\
& =\left(\sum_{j=0}^{\lfloor 0.5 m\rfloor-t}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j} \times 2^{m-2 j-2 t}\right) w+w .
\end{aligned}
$$

Similarly, a bound for $T_{5}$ can be as follows:

$$
\begin{equation*}
T_{5}<w+w \times 2^{m-2 t} \times\left(\frac{29}{32}\right)^{m} \approx w+w \times 2^{0.858 m-2 t} \tag{14}
\end{equation*}
$$

When there are $t>\lfloor 0.5 \mathrm{~m}\rfloor$ inactive S -boxes in the $(i+2)$-th round, the time complexity $T_{5}$ to enumerate all the valid difference transitions can be refined as below:

$$
\begin{equation*}
T_{5}=\left(\sum_{j=0}^{m}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j}\right) w=w \tag{15}
\end{equation*}
$$

Combining Equation 14 and Equation 15, we can know that whatever value $t$ takes, the following bound for $T_{5}$ holds

$$
\begin{equation*}
T_{5}<w+w \times 2^{0.858 m-2 t} \tag{16}
\end{equation*}
$$

### 8.3 Applications to 4-Round LowMC with a Full S-box Layer

As can be found in the latest released Picnic3 document, three recommended parameters $(n, k, m, D) \in\{(129,129,43,1),(192,192,64,1),(255,255,85,1)\}$ with $R=4$ are adopted to achieve the required security. By increasing the number of rounds by 1 , i.e. $R=5$, the designers claim that Picnic 3 will provide stronger security. Anyway, 4-round LowMC with a full S-box layer is the recommended instance and such three parameters are deemed as secure against the existing attacks [2]. In the following, we explain how to break such 3 parameters with our linearization techniques under the difference enumeration attack framework.

As depicted in Figure 6, our attack procedure consists of 4 steps:
Step 1: According to Equation 12, we find a suitable assignment for $\Delta_{0}^{S}$ such that the number of inactive S -boxes in the 2 nd round can be maximized and there is only one active S -box in the first round. Denote the number of inactive $S$-boxes in the 2 nd round by $q$.

Fig. 6: The attack framework for 4-round LowMC with a full S-box layer

Step 2: Choose a value for $\Delta_{0}$ such that it can reach $\Delta_{0}^{S}$ and encrypt two arbitrary plaintexts whose difference equals $\Delta_{0}$. Collect the corresponding ciphertexts and compute $\Delta_{3}^{S}$.
Step 3: Enumerate $4^{m-q}$ possible difference transitions from $\Delta_{1}$ to $\Delta_{2}$. For each possible difference transition, move to Step 4.
Step 4: For each obtained $\Delta_{2}$, we enumerate the possible difference transitions from $\Delta_{2}$ to $\Delta_{3}^{S}$ via solving a linear equation system, as detailed above. For each solution of the equation system, a compact differential trail is obtained and we retrieve the full key from it using our linearization techniques.

Although the formula to calculate the time complexity to retrieve the full key has been given, we should refine it for the attack on 4 -round LowMC with a full S-box layer. As can be observed in our attack procedure, once guessing $\Delta_{0}^{S}$ from its 4 possible values, we already collect two linear equations in terms of the master key and the plaintexts which can ensure that $\Delta_{0} \rightarrow \Delta_{0}^{S}$ is deterministic based on Observation 1 .

On the other hand, due to a sufficiently large number of S-boxes in each round, for the last round, we can introduce extra variables to represent the output bits of the inactive S -boxes. In this way, it is required to extract more than $k-2$ linear equations when a compact differential trail is confirmed. Specifically, assuming that there are $t$ inactive S -boxes in the 4 th round, the required number of equations becomes $3 t+k-2$. Therefore, we try to extract linear equations from the active $S$-boxes in the 3 rd round and 2 nd round, which requires that all the S-boxes in the 3rd are linearized. Therefore, the following formula can be used to estimate the expected time complexity to retrieve the full key from all compatible differential trails:

$$
T_{6}=4^{m-q} \times\left(\sum_{t=0}^{\left\lfloor\frac{6 m-k+2-2 q}{5}\right\rfloor}\binom{m}{t} \times\left(\frac{1}{8}\right)^{t} \times\left(\frac{7}{8}\right)^{m-t}\right.
$$

$$
\begin{aligned}
& \times \sum_{j=0}^{m}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j} \times 2^{2 j} \times 2^{m-2 j-2 t} \\
& +\sum_{t=\left\lfloor\frac{6 m-k+2-2 q}{5}\right\rfloor+1}^{m}\binom{m}{t} \times\left(\frac{1}{8}\right)^{t} \times\left(\frac{7}{8}\right)^{m-t} \\
& \times \sum_{j=0}^{m}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j} \times 2^{2 j} \\
& \left.\times 2^{(3 t+k-2)-(2(m-t)+2 m+2(m-q))} \times 2^{m-2 j-2 t}\right)
\end{aligned}
$$

Specifically, when there are $t$ and $j$ inactive S-boxes in the 4 th and 3rd round, respectively, the equation system used to retrieve the master key will be of size $2+2(m-t)+2 m+2(m-q)$ and in terms of $3 t+k$ variables. More specifically, from the assumed difference transition $\Delta_{0} \rightarrow \Delta_{0}^{S}$, two linear equations in terms of the master key and the plaintext can be obtained. From the 4 th round, as there are $(m-t)$ active S-boxes, $2(m-t)$ equations are obtained. For the 3 rd round, we linearize all the $j$ inactive S -boxes by guessing two extra equations based on Observation 5, i.e. guessing two output bits of each inactive S-box. In this way, there will always be $2 m$ equations derived from the 3 rd round. For the 2nd round, as the 4 th round and 3 rd round are fully linearized and there are $(m-q)$ active S-boxes, we can obtain $2(m-q)$ linear equations in the 2 nd round. Thus, if $3 t+k-(2+2(m-t)+2 m+2(m-q))<0 \rightarrow 5 t<6 m-k+2-2 q$, the cost is to establish the equation system. When $5 t \geq 6 m-k+2-2 q$, it is necessary to enumerate all the $2^{(3 t+k-2)-(2(m-t)+2 m+2(m-q))}$ solutions and check them via the plaintext-ciphertext pair.
$\Delta_{3}^{S}$ is a fixed random value. In our attack using only two chosen plaintexts, $\Delta_{3}^{S}$ is a random fixed value while $\Delta_{2}^{S}$ behaves randomly. Similar to computing the upper bound for the time complexity to enumerate differences for this case, i.e. Equation 14 and Equation 15, we also try to deal with the time complexity $T_{6}$ to retrieve the master key for this case. Similarly, we assume that there are $t$ inactive S-boxes in the 4 th round.

When $t \leq\left\lfloor\frac{6 m-k+2-2 q}{5}\right\rfloor$, we have

$$
\begin{equation*}
T_{6}=4^{m-q} \times \sum_{j=0}^{m}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j} \times 2^{2 j} \times 2^{m-2 j-2 t}=2^{3 m-2 q-2 t}( \tag{17}
\end{equation*}
$$

When $t>\left\lfloor\frac{6 m-k+2-2 q}{5}\right\rfloor$, we have

$$
\begin{aligned}
T_{6} & =4^{m-q} \times \sum_{j=0}^{m}\binom{m}{j} \times\left(\frac{1}{8}\right)^{j} \times\left(\frac{7}{8}\right)^{m-j} \times 2^{2 j} \\
& \times 2^{-6 m+k-2+2 q+5 t} \times 2^{m-2 j-2 t}=2^{-3 m+3 t+k-2}
\end{aligned}
$$

As $k=3 m$ for the construction using a full s-box layer, when $t>\left\lfloor\frac{6 m-k+2-2 q}{5}\right\rfloor$, we indeed have

$$
\begin{equation*}
T_{6}=2^{3 t-2} \tag{18}
\end{equation*}
$$

Remark. Indeed, when $t \leq\left\lfloor\frac{6 m-k+2-2 q}{5}\right\rfloor$, Equation 17 is an overestimation of the time complexity to retrieve the key. Specifically, when there are a sufficient number of active S-boxes in the 3rd round, there is no need to linearize the nonactive S-boxes in the 3 rd round. Formally, assuming that there are $j$ inactive S-boxes in the 3 rd round, when $2 \times(m-j+m-t)+2 \geq k+3 \times t$, i.e. $5 t \leq 4 m-k+2-2 j<6 m-2 q-k+2$, the time complexity to retrieve the key is 1 rather than $2^{2 j}$. Therefore, Equation 17 is an overestimation of the time complexity in order to achieve a simple approximation of the time complexity.

Attacks on $(129,129,43,1,4)$. For $(n, k, m, D, R)=(129,129,43,1,4)$, we have $V(129,11)>1$ based on Equation 12 i.e. we can expect to find an assignment to $\Delta_{0}^{S}$ such that there will be $q=11^{8}$ inactive S-boxes in the 2nd round. After such a $\Delta_{0}^{S}$ is chosen, we randomly choose $\Delta_{0}$ such that $\Delta_{0} \rightarrow \Delta_{0}^{S}$ is valid. There are 4 different values of $\Delta_{0}^{S}$ for such a $\Delta_{0}$ and one of $\Delta_{0}^{S}$ is expected to inactivate 11 S-boxes in the second round.

The time complexity to retrieve the master key from all valid 4-round compact differential trails is related to the value of $(t, q)$. As $t \sim \mathcal{B}\left(m, \frac{1}{8}\right)$ where $\mathcal{B}$ represents the binomial distribution, we can expect $t=5$. In this way, we have $5 t=25<6 m-k+2-2 q=131-2 q$ whatever value $q(0 \leq q \leq m)$ takes. In other words, for the expected case $q=11$, the time complexity to retrieve the master key is $2^{3 m-2 q-2 t}=2^{97}$ based on Equation 17. By taking the remaining 3 different possible values of $\Delta_{0}^{S}$ into account, even for the worst case $(q=0)$, the total time complexity to retrieve the master key for all 4 possible values of $\Delta_{0}^{S}$ will not exceed $3 \times 2^{3 m-2 t}=2^{120.6}$, i.e. less than exhaustive key search.

For the time complexity to enumerate the difference, for the expected case $q=11$, we have $T_{5}<2^{2 m-2 q} \times\left(1+2^{0.858 m-2 t}\right)=2^{2.858 m-2 q-2 t}+2^{2 m-2 q}=2^{90.9}$ based on Equation 16. For the worst case $q=0$, we have $T_{5}<2^{2.858 m-2 t}=2^{112.9}$. Therefore, the total time complexity to enumerate the difference will not exceed $3 \times 2^{112.9} \approx 2^{114.5}$. i.e. less than exhaustive key search.

As $t$ increases, $T_{5}$ will become smaller. However, when $5 t \geq 6 m-k+2-2 q=$ $132-2 q$, we need to use another formula to calculate the time complexity to retrieve the master key, i.e. $T_{6}=2^{3 t-2}$ as shown in Equation 18. As $3 t<3 m=k$ must holds, it means that the time complexity $T_{6}$ is always smaller than that of the exhaustive search.

As $\operatorname{Pr}[t \geq 4] \approx 0.62$ and $\operatorname{Pr}[42 \leq t \leq 43] \approx 0$, we conclude that with success probability 0.62 , the total time complexity to retrieve the master key will be $\max \left(3 \times 2^{3 m-2 t}, 4 \times 2^{3 \times 41-2}\right)=2^{122.6}$ and the total time complexity to enumerate differences will not exceed $3 \times 2^{2.858 m-2 t}<2^{117.5}$. Thus, we can break the parameter $(n, k, m, D, R)=(129,129,43,1,4)$ with time complexity less than $2^{122.6}$ and success probability 0.62 .

As $\operatorname{Pr}[t \geq 2] \approx 0.97$ and $\operatorname{Pr}[36 \leq t \leq 43] \approx 0$, if further reducing the success probability to $0.97 \times 0.25=0.24$, i.e. $\Delta_{0} \rightarrow \Delta_{0}^{S}$ is assumed to be deterministic and we expect $q=11$, the time complexity to enumerate the difference will not

[^2]exceed $2^{2 m-2 q}+2^{2.858 m-2 q-2 t} \approx 2^{96.9}$ and the time complexity to retrieve the master key be $\max \left(2^{3 m-2 q-2 t}, 2^{3 t-2}\right)<2^{104}$.

A similar detailed description of our attacks on another two parameters can be referred to Appendix C. All the results are summarized in Table 3.

Table 3: The results for 4-round LowMC with a full S-box layer

| $n$ | $k$ | $m$ | $D$ | $R$ | Data | Time | Memory | Success Pro. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 129 | 129 | 43 | 1 | 4 | 2 | $2^{122.6}$ | negligible | 0.62 |
| 129 | 129 | 43 | 1 | 4 | 2 | $2^{104}$ | negligible | 0.24 |
| 192 | 192 | 64 | 1 | 4 | 2 | $2^{187.6}$ | negligible | 0.99 |
| 192 | 192 | 64 | 1 | 4 | 2 | $2^{180}$ | negligible | 0.82 |
| 192 | 192 | 64 | 1 | 4 | 2 | $2^{156}$ | negligible | 0.247 |
| 255 | 255 | 85 | 1 | 4 | 2 | $2^{246.6}$ | negligible | 0.986 |
| 255 | 255 | 85 | 1 | 4 | 2 | $2^{236.6}$ | negligible | 0.848 |
| 255 | 255 | 85 | 1 | 4 | 2 | $2^{208}$ | negligible | 0.2465 |

## 9 Experiments

To confirm the correctness of our methods, we performed experiments 9 on two toy LowMC instances with parameters $(n, k, m, D, R)=(20,20,1,1,23)$ and $(n, k, m, D, R)=(21,21,7,1,4)$, respectively.

For the first parameter, $R=23$ is the largest number of rounds that can be attacked, i.e. $r_{0}=6, r_{1}=7$ and $r_{2}=10$. The time complexity to enumerate the differences is estimated as $2^{1.86 r_{2}} \approx 397336$. The expected number of valid compact differential trails is $2^{1.86\left(r_{1}+r_{2}\right)-n} \approx 3147$. Experimental results indeed match well with the estimated values ${ }^{10}$. As the time complexity to recover the key is affected by the number of inactive S-boxes, for each valid compact differential trail obtained in the experiments, we counted the number of inactive S-boxes in the last 10 rounds, which will dominate the time to recover the key as each S-box will give us 2 equations and there are 10 S-boxes in the last 10 rounds. The distribution of the number of inactive S-boxes is somewhat better than expected, thus resulting that the time to recover the key is better than the estimated time $3147 \times 2^{0.46 \times 10} \approx 76319$. Anyway, the total time complexity is dominated by the backward difference enumeration.

For the parameter $(n, k, m, D, R)=(21,21,7,1,4)$, we constrained that the difference transition in the first round follows our expectation by checking $\Delta_{0}^{s}$ when encrypting two plaintexts, i.e. the number of inactive S-boxes in the second round will be maximized. Based on the generated matrix $L_{0}$, there will be 3

[^3]inactive S-boxes in the second round. Then, the output difference of the first round is fixed and we enumerate the output differences of the second round and compute all possible compact differential trails by solving an equation system. In several experiments with 10000 tests each, the time to enumerate all compact differential trails is smaller than the upper bound computed based on Equation 16 with probability higher than 0.99 and they are almost the same in the remaining tests. Then, the time to recover the key is computed based on the number of active S-boxes in the last 3 rounds for each valid compact differential trail by summing the costs of guess ${ }^{11}$ or enumerating solutions. It is found that the obtained value is almost the same with the theoretical value computed based on Equation 17 or Equation 18 .

## 10 Conclusion

Benefiting from the low-degree S-box and the linear key schedule function of LowMC, we developed an efficient algebraic technique to solve a general problem of how to retrieve the key if given a single pair of (plaintext, ciphertext) along with its compact differential trail. Such a technique is quite meaningful as much more differential trail candidates are allowed to exist under the difference enumeration attack framework. As a result, we could significantly extend the number of attacked rounds even with only 2 chosen plaintexts.

On the other hand, by exploiting the fact that only a few S-boxes are applied to the state, we could simulate the difference transitions over rounds by constructing a linear equation system, thus requiring negligible memory complexity. Such a strategy performs quite well for the cases when the block size is much larger and when a full S-box layer is adopted. Especially for the latter case, much more invalid difference transitions can be filtered in advance as all valid difference transitions are constrained by a linear equation system.

Combining all our techniques, we violate the security claim for some instances of LowMC. Especially, the 3 recommended parameters of LowMC used in Picnic3 are shown to be insecure against our attacks. As the backdoor cipher LowMC-M is built on LowMC, making progress in the cryptanalysis of LowMC directly threatens the security claim for 7 instances of LowMC-M even without finding the backdoor.

## Supplemental Material

## A Description of LowMC-M

LowMC-M [23] is a family of tweakable block ciphers built on LowMC, which is introduced by Peyrin and Wang in CRYPTO 2020. The feature of LowMC-M is that backdoors can be inserted in the instantiation. The only difference between LowMC and LowMC-M is that there is an addition operation AddSubTweak (AT) after AK and WK. In other words, the round function in the $(i+1)$ round $(0 \leq i \leq R-1)$ can be described as follows:

1. SBoxLayer (SB): Same with LowMC.
2. LinearLayer (L): Same with LowMC.
3. ConstantAddition (AC): Same with LowMC.
4. KeyAddition (AK): Same with LowMC.
5. AddSubTweak (AT): Add an $n$-bit sub-tweak $T W_{i+1}$ to the $n$-bit state.

For the state after $\mathbf{W K}$, it will also be XORed with an $n$-bit sub-tweak $T W_{0}$.
To strengthen the security of the backdoors, $T W_{i}(0 \leq i \leq R)$ are generated via an extendable-output-function (XOF) function. SHAKE-128 and SHAKE256 are used as the XOF functions in LowMC-M for 128 -bit and 256 -bit security respectively. Specifically, the tweak $T W$ is the input of the XOF function and the corresponding $n(R+1)$-bit output will be split into $(R+1)$ sub-tweaks $T W_{i}$, i.e. $\left(T W_{0}, T W_{1}, \cdots, T W_{R}\right) \leftarrow \operatorname{XOF}(T W)$.

## B Exploiting the Tweak to Maximize $r_{0}$ for LowMC-M

In brief, when there is no active $S$-box in the first $r_{0}$ rounds, an attacker can construct a linear equation system of size $3 m r_{0}$ and in terms of $\Delta_{0}$ as well as the difference of sub-tweaks $\left(\Delta T W_{0}, \cdots, \Delta T W_{r_{0}-1}\right)$. When the sub-tweaks are fixed, the equation system is thus only in terms of $\Delta_{0}$, i.e. $n$ variables. Therefore, when $3 m r_{0}>n$, the equation system is consistent with probability $2^{n-3 m r_{0}}$. Thus, the attacker needs to find an assignment for $\left(\Delta T W_{0}, \cdots, \Delta T W_{r_{0}-1}\right)$ such that the constructed equation system is consistent.

To achieve this goal, the equation system will be first re-organized by placing $\left(\Delta T W_{0}, \cdots, \Delta T W_{r_{0}-1}\right)$ on the right-hand of the equation system and placing $\Delta_{0}$ on the left-hand of the equation system. In other words, the equation system becomes

$$
A \cdot \Delta_{0}=B \cdot\left(\Delta T W_{0}, \cdots, \Delta T W_{r_{0}-1}\right)
$$

where $A$ is a binary matrix of size $3 m r_{0} \times n$ and $B$ is a binary matrix of size $3 m r_{0} \times n r_{0}$. To ensure that there is a solution to $\Delta_{0}$, one can derive an equation system of size $3 m r_{0}-n$ and only in terms of $\left(\Delta T W_{0}, \cdots, \Delta T W_{r_{0}-1}\right)$. Specifically, apply a transform $A_{3 m r_{0} \times 3 m r_{0}}^{\prime}$ to both $A$ and $B$ such that the first $n$ rows of $A^{\prime} \cdot A$ is an identity matrix and the remaining $\left(3 m r_{0}-n\right)$ rows of $A^{\prime} \cdot A$ are all zero. In this way, we only need to focus on the last $\left(3 m r_{0}-n\right)$ rows of $A^{\prime} \cdot B$, i.e. a linear equation system of size $3 m r_{0}-n$ and in terms of ( $\Delta T W_{0}, \cdots, \Delta T W_{r_{0}-1}$ ) can be derived to ensure that there is always a solution to $\Delta_{0}$. Thus, with a parallel collision search [28, it is expected to find $\left(\Delta T W_{0}, \cdots, \Delta T W_{r_{0}-1}\right)$ with time complexity $2^{\frac{3 m r_{0}-n}{2}}$ and negligible memory satisfying such an equation system. Therefore, the constraint for $r_{0}$ becomes

$$
\begin{equation*}
\frac{3 m r_{0}-n}{2}<k \tag{19}
\end{equation*}
$$

In this way, one could find the desirable pair of tweaks as well as the plaintext difference $\Delta_{0}$ with time complexity $2^{\frac{3 m r_{0}-n}{2}}$. This is the method given in [8] to maximize $r_{0}$.

## C Explanation of the Attacks on LowMC with a Full S-box Layer

Attacks on $(192,192,64,1,4)$. Similar to the above analysis, we first confirm $q$. As $V(192,15)>1$ based on Equation 12 we can expect to always find an assignment to $\Delta_{0}^{S}$ such that there will be $q=15^{12}$ inactive S-boxes in the 2nd round.

As $\operatorname{Pr}[t \geq 3] \approx 0.99$ and $\operatorname{Pr}[62 \leq t \leq 64] \approx 0$, based on Equation 17 and Equation 18, the time complexity to retrieve the master key will be $\max \left(3 \times 2^{3 m-2 t}, 4 \times 2^{3 t-2}\right)<2^{187.6}$. Based on Equation 16 , the time complexity to enumerate the difference is less than $3 \times\left(2^{2 m}+2^{2 m-2 t+0.858 m}\right)=3 \times\left(2^{2 m}+\right.$ $\left.2^{2.858 m-2 t}\right)<2^{178.5}$. Therefore, we could break $(n, k, m, D, R)=(192,192,64,1,4)$ with time complexity less than $2^{187.6}$ and success probability 0.99.

As $\operatorname{Pr}[t \geq 6]=0.82$ and $\operatorname{Pr}[61 \leq t \leq 64] \approx 0$, the time complexity to retrieve the master key will be $\max \left(3 \times 2^{3 m-2 t}, 4 \times 2^{3 t-2}\right)=2^{180}$, while the time complexity to enumerate the differences will not exceed $3 \times\left(2^{2 m}+2^{2.858 m-2 t}\right)<$ $2^{170.9}$. Therefore, we could break $(n, k, m, D, R)=(192,192,64,1,4)$ with time complexity less than $2^{180}$ and success probability 0.82 .

To further reduce the success probability, we focus on the expected case $q=15$ and $3 \leq t \leq 52$. As $\operatorname{Pr}[t \geq 3] \approx 0.99$ and $\operatorname{Pr}[53 \leq t \leq 64] \approx 0$, we have $\operatorname{Pr}[3 \leq t \leq 52] \approx 0.99$. The time complexity to retrieve the master key becomes $\max \left(2^{3 m-2 t-2 q}, 2^{3 t-2}\right)<2^{156}$. The time complexity to enumerate the difference is less than $2^{2 m-2 q}+2^{2.858 m-2 t-2 q}<2^{146.9}$. Therefore, we could break $(n, k, m, D, R)=(192,192,64,1,4)$ with time complexity less than $2^{156}$ and success probability $0.99 \times 0.25=0.247$.

[^5]Attacks on $(255,256,85,1,4)$. For $(n, k, m, D, R)=(255,255,85,1,4)$, we have $V(255,19)>1$ based on Equation 12, i.e. we can expect to always find an assignment to $\Delta_{0}^{S}$ such that there will be $q=1 q^{13}$ inactive S-boxes in the 2nd round.

As $\operatorname{Pr}[t \geq 5] \approx 0.986$ and $\operatorname{Pr}[79 \leq t \leq 85] \approx 0$, based on Equation 17 and Equation 18 , the time complexity to retrieve the master key will be $\max \left(3 \times 2^{3 m-2 t}, 4 \times 2^{3 t-2}\right)<2^{246.6}$. Based on Equation 16 , the time complexity to enumerate the difference is less than $3 \times\left(2^{2 m}+2^{2 m-2 t+0.858 m}\right)=3 \times$ $\left(2^{2 m}+2^{2.858 m-2 t}\right)<2^{234.53}$. Therefore, we could break $(n, k, m, D, R)=$ $(255,255,85,1,4)$ with time complexity less than $2^{246.6}$ and success probability 0.986 .

As $\operatorname{Pr}[t \geq 8]=0.848$ and $\operatorname{Pr}[79 \leq t \leq 85] \approx 0$, the time complexity to retrieve the master key will be $\max \left(3 \times 2^{3 m-2 t}, 4 \times 2^{3 t-2}\right)<2^{240.6}$, while the time complexity to enumerate the differences will not exceed $3 \times\left(2^{2 m}+2^{2.858 m-2 t}\right)<$ $2^{228.53}$. Therefore, we could break $(n, k, m, D, R)=(255,255,85,1,4)$ with time complexity less than $2^{240.6}$ and success probability 0.848 .

To further reduce the success probability, we focus on the expected case $q=19$ and $5 \leq t \leq 85$. As $\operatorname{Pr}[t \geq 5] \approx 0.986$ and $\operatorname{Pr}[70 \leq t \leq 85] \approx 0$, we have $\operatorname{Pr}[5 \leq t \leq 69] \approx 0.986$. The time complexity to retrieve the master key becomes $\max \left(2^{3 m-2 t-2 q}, 2^{3 t-2}\right)<2^{208}$. The time complexity to enumerate the difference is less than $2^{2 m-2 q}+2^{2.858 m-2 t-2 q}<2^{194.93}$. Therefore, we could break $(n, k, m, D, R)=(255,255,85,1,4)$ with time complexity less than $2^{208}$ and success probability $0.986 \times 0.25=0.2465$.

[^0]:    ${ }^{6}$ In the security proof of Picnic, 2 plaintexts are required, which can be found at footnote 11 in Page 10 in 9 . This is also our motivation to analyze such instances with only 2 allowed plaintexts. In the security proof, the parameters with 2 allowed plaintexts are treated as secure.

[^1]:    ${ }^{7}$ If we use the equivalent representation of LowMC, such a statement is correct. If we do not use it, $A_{r-1}$ can be written as linear expressions in terms of $\left(v_{0}, \cdots, v_{3 m-1}\right)$ and the key bits, which will not affect our attack as our final goal is construct a linear equation system in terms of the $3 m r_{3}$ variables and the key bits. For simplicity, we consider the equivalent representation.

[^2]:    ${ }^{8}$ Experiments show that it is better to choose $q=11$, though $V(129,12)>1$.

[^3]:    ${ }^{9}$ See https://github.com/LFKOKAMI/LowMC_Diff_Enu.git for the code.
    ${ }^{10}$ In several experiments with 1000 random tests each, the average time to enumerate differences is $392500 \pm 12500$ and the average number of valid compact differential trails is $3425 \pm 125$.

[^4]:    ${ }^{11}$ The S-boxes in the 3rd round will be fully linearized, though it is an overestimation.

[^5]:    ${ }^{12}$ It can be found that $V(192,16)$ is only slightly greater than 1 . Experiments show that it is better to choose $q=15$.

[^6]:    ${ }^{13}$ It can be found that $V(255,20)$ is only slightly greater than 1 . Experiments show that it is better to choose $q=19$.
