#### Abstract

We demonstrate the soundness proof for the De Feo, Jao and Plût identification scheme (the basis for SIDH signatures) contains an invalid assumption and provide a counterexample for this assumption - thus showing the proof of soundness is invalid. As this proof was repeated in a number of works by various authors, multiple pieces of literature are affected by this result. Due to the importance of being able to prove knowledge of an SIDH key (for example, to prevent adaptive attacks), soundness is a vital property. We propose a modified identification scheme fixing the issue with the De Feo, Jao and Plût scheme, and provide a proof of security of this new scheme. We also prove that a modification of this scheme allows the torsion points in the public key to be verified too. This results in a secure proof of knowledge for SIDH keys and a secure SIDH-based signature scheme. In particular, these schemes provide a non-interactive way of verifying that SIDH public keys are well formed as protection against adaptive attacks, more efficient than generic NIZKs.

## 1 Introduction

While Supersingular-Isogeny Diffie-Hellman (SIDH) JD11, DJP14 is a fast and efficient post-quantum key exchange candidate, it has been hampered by the existence of practical adaptive attacks on the scheme the first of these given by Galbraith et al. GPST16] (the GPST attack). These attacks mean it is not safe to re-use a static key across multiple SIDH exchanges without other forms of protection. As such, various countermeasures have been proposed - though each with their unique drawbacks.

The first of these is to require one participant to use a one-time ephemeral key in the exchange, accompanied by a Fujisaki-Okamoto transform revealing the corresponding secret to the other party. This allows the recipient to verify the public key is well formed, ensuring an adaptive attack was not used. This is what was done in SIKE [ACC ${ }^{+} 17$, and converts the scheme to a secure key encapsulation mechanism (KEM). But it is of limited use in cases where both parties wish to use a long-term key.

The second countermeasure is to use many SIDH exchanges in parallel, combining all the resulting secrets into a single value, as proposed by Azarderakhsh, Jao, and Leonardi AJL17. This scheme is known as $k$-SIDH, where $k$ is the number of keys used by each party in the exchange. The authors suggest $k=92$ is required for a secure key exchange, as Dobson et al. DGL ${ }^{+} 20$ demonstrate how the GPST adaptive attack can be ported to $k=2$ and above. Note that the number of SIDH instances grows as $k^{2}$, so this scheme is very inefficient. Urbanik and Jao UJ20's proposal attempted to improve the efficiency of this protocol by making use of the special automorphisms on curves with $j$-invariant 0 or 1728 , but it was shown by Basso et al. $\left.\mathrm{BKM}^{+} 20\right]$ that Urbanik and Jao's proposal is vulnerable to a more efficient adaptive attack and actually scales worse in efficiency than $k$-SIDH itself (although the public keys are around $4 / 5$ of the size, it requires around twice as many SIDH instances for the same security).

Finally, adaptive attacks can also be prevented by providing a non-interactive proof that a public key is wellformed or honestly generated. While generic NIZKs would make this possible in a very inefficient manner, Urbanik and Jao UJ20 claim a method for doing so using a similar idea to their $k$-SIDH improvement mentioned above. Their scheme is based on the SIDH-based identification scheme by De Feo, Jao and Plût DJP14.
Unfortunately, however, we show that the soundness of this original De Feo, Jao and Plût scheme is not rigorously proved - specifically that it does not reduce to the computational assumption they claim and give a counterexample to this proof. Because this scheme (and proof) has since been used to build an undeniable signature by Jao and Soukharev [JS14, a signature scheme by Yoo, Azarderakhsh, Jalali, Jao and Soukharev [YAJ ${ }^{+17]}$, and also by Galbraith, Petit and Silva [GPS20], all of these subsequent papers suffer from the same issue. Our counterexample does not apply to Urbanik and Jao's scheme, but their soundness proof nonetheless does not hold for the same reason.
In this work we examine the issue with the existing soundness proofs and propose a new SIDH-based identification scheme which we prove does satisfy special soundness. We then propose a modification to the scheme which allows the two torsion points in the public key to be proved correct as well, which were not covered by De Feo, Jao and Plût's scheme. This gives a secure method for proving well-formedness of SIDH public keys - the first sound Proof of Knowledge protocol of a secret isogeny for a given public key with important applications in all areas where SIDH key exchanges could be used with static keys. What's more, our scheme works with any base elliptic curve, rather than being restricted to the two curves with $j$-invariant 0 or 1728 as in UJ20. While the size of our NIZK proof is larger than a $k$-SIDH public key of the same security level, it is much more efficient to verify than computing a $k$-SIDH exchange (due to the quadratic scaling mentioned above).
In concurrent independent work, Ghantous et al. GPV21 have demonstrated that the soundness property for the De Feo, Jao and Plût scheme (and those based on it) fails for a different reason - namely the existence of multiple isogenies of the same length between some curves. The new scheme we propose in this paper does not suffer from the issue Ghantous et al. analyze, but this further solidifies the need for a sound replacement to prove honest generation of SIDH public keys - of which ours is the first.

### 1.1 Outline

This work begins in Section 2 with revision of some preliminary background material. We then recall the De Feo-Jao-Plût identification scheme in Section 3.1 and outline the issue with its proof of soundness (given in multiple previous works) in Section 3.2. Subsequently, we present a new SIDH identification scheme in Section 4 which modifies the De Feo-Jao-Plût scheme and allows us to prove soundness (and thus security). We then show how the points in the SIDH public key can also be verified under this identification scheme in Section 5, and discuss improvements to the efficiency of this scheme. From this, we construct a secure signature scheme which is a Proof of Knowledge (PoK) of an SIDH secret key, and is the first such scheme which is sound and proves correctness of the points in the public key (a protection mechanism against adaptive attacks [GPST16, DGL ${ }^{+} 20$ ) in Section 6 .

### 1.2 Acknowledgements

Thank you to David Jao, Jason LeGrow, and Yi-Fu Lai for useful discussion about this work. Thank you also to Paulo Barreto for catching some typos in this paper, and to Simon-Philipp Merz for valuable comments.

## 2 Preliminaries

Notation. We begin with some notation and conventions that we will use throughout this paper. We will use $K_{\phi}$ to denote a point which generates the kernel of an isogeny $\phi$. Let $[t]$ denote the set $\{1, \ldots, t\}$.

### 2.1 SIDH

We now provide a brief refresher on the Supersingular Isogeny Diffie-Hellman (SIDH) key exchange protocol JD11, DJP14 by De Feo, Jao, and Plût.
As public parameters, we have a prime $p=\ell_{1}^{e_{1}} \cdot \ell_{2}^{e_{2}} \cdot f \pm 1$, where $\ell_{1}, \ell_{2}$ are small primes, $f$ is an integer cofactor, and $\ell_{1}^{e_{1}} \approx \ell_{2}^{e_{2}}$. We work over the finite field $\mathbb{F}_{p^{2}}$. Additionally we fix a base supersingular elliptic curve $E_{0}$ and bases $\left\{P_{1}, Q_{1}\right\},\left\{P_{2}, Q_{2}\right\}$ for both the $\ell_{1}^{e_{1}}$ and $\ell_{2}^{e_{2}}$ torsion subgroups of $E_{0}\left(\mathbb{F}_{p^{2}}\right)$ respectively (such that $E_{0}\left[\ell_{i}^{e_{i}}\right]=\left\langle P_{i}, Q_{i}\right\rangle$ ). Typically $\ell_{1}=2$ and $\ell_{2}=3$.

It is well known that knowledge of an isogeny and knowledge of its kernel are equivalent, and we can convert between them at will, via Vélu's formulae Vél71. In SIDH, the secret key of Alice (respectively Bob) is an isogeny $\phi: E\left(\mathbb{F}_{p^{2}}\right) \rightarrow E_{A}\left(\mathbb{F}_{p^{2}}\right)$ of degree $\ell_{1}^{e_{1}}$ (respectively $\ell_{2}^{e_{2}}$ ). These isogenies are generated by randomly choosing secret integers $a_{i}, b_{i} \in \mathbb{Z} / \ell_{i}^{e_{i}} \mathbb{Z}$ (not both divisible by $\ell_{i}$ ) and computing the isogeny with kernel $K_{i}=\left\langle\left[a_{i}\right] P_{i}+\left[b_{i}\right] Q_{i}\right\rangle$. We thus unambiguously refer to the isogeny, its kernel, and such integers $a, b$, as "the secret key." Figure 1 depicts the commutative diagram making up the key exchange.

Figure 1: Commutative diagram of SIDH, where $\operatorname{ker}\left(\phi_{B A}\right)=\phi_{B}\left(\operatorname{ker}\left(\phi_{A}\right)\right)$ and $\operatorname{ker}\left(\phi_{A B}\right)=\phi_{A}\left(\operatorname{ker}\left(\phi_{B}\right)\right)$.
In order to make the diagram commute, Alice and Bob are required to not just give their image curves $E_{A}$ and $E_{B}$ in their respective public keys, but also the images of the basis points of the other participant's kernel on $E$. That is, Alice provides $E_{A}, P_{2}^{\prime}=\phi_{A}\left(P_{2}\right), Q_{2}^{\prime}=\phi_{A}\left(Q_{2}\right)$ as her public key. This allows Bob to "transport" his secret isogeny to $E_{A}$ and compute $\phi_{A B}$ whose kernel is $\left\langle\left[a_{2}\right] P_{2}^{\prime}+\left[b_{2}\right] Q_{2}^{\prime}\right\rangle$. Both Alice and Bob will arrive along these transported isogenies at isomorphic image curves $E_{A B}, E_{B A}$ (using Vélu's formulae, they will actually arrive at exactly the same curve). Two elliptic curves are isomorphic over $\overline{\mathbb{F}}_{p^{2}}$ if and only if their $j$-invariants $j\left(E_{A B}\right)=j\left(E_{B A}\right)$, hence this $j$-invariant may be used as the shared secret of the SIDH key exchange.

Remark 1. Galbraith et al. GPST16, Lemma 2.1] formally presented the idea of "equivalent keys" (which were previously implicit in some previous work including Costello et al. CLN16). Two secret keys ( $a, b$ ) and $\left(a^{\prime}, b^{\prime}\right)$ are equivalent if they generate the same subgroup for any basis of the $\ell_{i}^{e_{i}}$ torsion subgroup. This is true when $\left(a^{\prime}, b^{\prime}\right)=(\theta a, \theta b)$ for $\theta \in \mathbb{Z}_{\ell_{i}}^{*}$. Because we have the condition that at least one of $a, b$ is not divisible by $\ell_{i}$ (assume for now this is $a$ ), $a$ is invertible modulo $\ell_{i}^{e_{i}}$. Thus we can choose $\theta \equiv a^{-1}\left(\bmod \ell_{i}^{e_{i}}\right)$. This gives an equivalent key $\left(1, b^{\prime}\right)$. Similarly, if $b$ was not divisible by $\ell_{i}$, we can invert it and obtain equivalent key $\left(a^{\prime}, 1\right)$. Hence we obtain a shorter representation of secret keys without loss of generality, to a single element and one extra bit.

### 2.2 SIDH assumptions

We shall recall the standard isogeny-based hardness assumptions of relevance to this work.
Definition 1 (General isogeny problem). Given $j$-invariants $j, j^{\prime} \in \mathbb{F}_{p^{2}}$, find an isogeny $\phi: E \rightarrow E^{\prime}$ if one exists, where $j(E)=j$ and $j\left(E^{\prime}\right)=j^{\prime}$.

This is the foundational hardness assumption of isogeny-based cryptography, that it is hard to find an isogeny between two given curves. Note the decisional version, determining whether an isogeny exists, is easy - an isogeny exists if and only if the cardinality $\# E\left(\mathbb{F}_{p^{2}}\right)=\# E^{\prime}\left(\mathbb{F}_{p^{2}}\right)$.

Definition 2 (Computational Supersingular Isogeny (CSSI) problem). For fixed SIDH public parameters $\left(p, E_{0}, P_{1}, Q_{1}, P_{2}, Q_{2}\right)$, let $\phi: E_{0} \rightarrow E_{A}$ be an isogeny of degree $\ell_{1}^{e_{1}}$. Given the SIDH public key $\left(E_{A}, P=\right.$ $\left.\phi\left(P_{2}\right), Q=\phi\left(Q_{2}\right)\right)$, find an isogeny $\phi^{\prime}: E_{0} \rightarrow E_{A}$ of degree $\ell_{1}^{e_{1}}$ such that $P, Q=\phi^{\prime}\left(P_{2}\right), \phi^{\prime}\left(Q_{2}\right)$.
This is problem 5.2 of [DJP14], and essentially states that it is hard to find the secret key corresponding to a given public key. This problem is also called the SIDH isogeny problem by [GV18, Definition 2].

Definition 3 (Decisional SIDH isogeny problem (DSIDH) problem). Let $E$ be an elliptic curve and $P, Q$ a basis such that $E\left[\ell_{2}^{e_{2}}\right]=\langle P, Q\rangle$. Let $E^{\prime}$ be an elliptic curve and let $P^{\prime}, Q^{\prime}$ be a basis of $E^{\prime}\left[\ell_{2}^{e_{2}}\right]$. The decisional SIDH problem is, given $\left(E, P, Q, E^{\prime}, P^{\prime}, Q^{\prime}\right)$, to determine whether or not there exists an isogeny $\phi: E \rightarrow E^{\prime}$ of degree $\ell_{1}^{e_{1}}$ such that $P^{\prime}=\phi(P)$ and $Q^{\prime}=\phi(Q)$.
This is Definition 3 of GV18, and is also very similar to the key validation problem of Urbanik and Jao UJ18, Problem 3.4] (the key validation problem asks whether a $\phi$ of degree dividing $\ell_{1}^{e_{1}}$ exists). It is known that an adversary against the DSIDH problem (where the isogeny degree is an input parameter to the decision oracle) can be used to solve the CSSI problem (by testing neighboring curves and learning the correct path one bit at a time).
Definition 4 (Decisional Supersingular Product (DSSP) problem). Let $E_{0}, E_{1}$ be supersingular elliptic curves such that there exists an isogeny $\phi: E_{0} \rightarrow E_{1}$ of degree $\ell_{1}^{e_{1}}$ between them. Let $P_{2}, Q_{2} \in E_{0}\left[\ell_{2}^{e_{2}}\right]$ be a fixed basis of the $\ell_{2}^{e_{2}}$ torsion subgroup. Suppose we have the following two distributions:

- $\left(E_{2}, E_{3}, \phi^{\prime}\right)$ such that there exists a cyclic subgroup $G \subseteq E\left[\ell_{2}^{e_{2}}\right]$ of order $\ell_{2}^{e_{2}}$ and $E_{2} \cong E_{0} / G$ and $E_{3} \cong E_{1} / \phi(G)$, and $\phi^{\prime}: E_{2} \rightarrow E_{3}$ is a degree $\ell_{1}^{e_{1}}$ isogeny.
- $\left(E_{2}, E_{3}, \phi^{\prime}\right)$ such that $E_{2}$ is a random supersingular curve with the same cardinality as $E_{0}$, and $E_{3}$ is the codomain of a random isogeny $\phi^{\prime}: E_{2} \rightarrow E_{3}$ of degree $\ell_{1}^{e_{1}}$.

The Decisional Supersingular Product problem is, given $E_{0}, E_{1}$ as well as the points $P_{2}, Q_{2}, \phi\left(P_{2}\right), \phi\left(Q_{2}\right)$, and given a tuple $\left(E_{2}, E_{3}, \phi^{\prime}\right)$ drawn randomly with probability 1/2 from the above two distributions, to determine which of the two distributions it was drawn from.
This is problem 5.5 of DJP14 and intuitively states that it is hard to determine whether there exists valid "vertical sides" to an SIDH square given the corners and the bottom horizontal side.

### 2.3 Sigma protocols

A sigma protocol $\Pi_{\Sigma}$ for a relation $\mathcal{R}=\{(X, W)\}$ is a public-coin three-move interactive proof system consisting of two parties: a verifier $V$ and a prover $P$.

Definition 5 (Sigma protocol). A sigma protocol $\Pi_{\Sigma}$ for a family of relations $\{\mathcal{R}\}_{\kappa}$ parametrized by security parameter $\kappa$ consists of PPT algorithms $\left(\left(P_{1}, P_{2}\right),\left(V_{1}, V_{2}\right)\right)$ where $V_{2}$ is deterministic and we assume $P_{1}, P_{2}$ share states. The protocol proceeds as follows:

1. Round 1: The prover, on input $(X, W) \in \mathcal{R}$, returns a commitment com $\leftarrow P_{1}(X, W)$ and sends com to the verifier.
2. Round 2: The verifier, on receipt of com, runs chall $\leftarrow V_{1}\left(1^{\kappa}\right)$ to obtain a random challenge, and sends this to the prover.
3. Round 3: The prover then runs resp $\leftarrow P_{2}(X, W$, chall) and returns resp to the verifier.
4. Verification: The verifier runs $V_{2}(X$, com, chall, resp) and outputs either $\top$ (accept) or $\perp$ (reject).

A transcript (com, chall, resp) is said to be valid if $V_{2}(X$, com, chall, resp) outputs $\top$. Let $\langle P, V\rangle$ denote the transcript for interaction between prover $P$ and verifier $V$. Relevant properties of a sigma protocol are:

Correctness: If the prover $P$ knows $(X, W) \in \mathcal{R}$ and behaves honestly, then the verifier $V$ accepts.

2-special soundness: There exists a polynomial time extraction algorithm Extract, which given a statement $X$ and two valid transcripts (com, chall, resp) and (com, chall', resp') where chall $\neq$ chall ${ }^{\prime}$, outputs a witness $W$ such that $(X, W) \in \mathcal{R}$ with probability at least $1-\varepsilon$ for soundness error $\varepsilon$.
Zero Knowledge (ZK): There exists a polynomial time simulator Sim, which given a statement $X$ for any $(X, W) \in \mathcal{R}$, and for any (cheating) verifier $V^{*}$, outputs transcripts (com, chall, resp) that are indistinguishable from valid interactions between a prover $P$ and $V^{*}$.

Proof of Knowledge (PoK): There exists a polynomial time extraction algorithm Extract, which given an arbitrary statement $X$ and access to any prover $P^{*}$, outputs a witness $W$ such that $(X, W) \in \mathcal{R}$ with probability at least $\operatorname{Pr}\left[\left\langle P^{*}, V\right\rangle=1\right]-\varepsilon$ for knowledge error $\varepsilon$.
It is a known result (e.g. by Hazay and Lindell HL10, Theorem 6.3.2]) that a correct and special-sound sigma protocol with challenge length $t$ is a proof of knowledge with knowledge error $2^{-t}$. In this paper, this will generally be a single-bit challenge sigma protocol repeated with $t$ iterations.

### 2.4 Seed trees

We briefly recall the definition of a seed tree from Beullens et al. BKP20. A seed tree is used to generate a number of pseudorandom values and later disclose an arbitrary subset of them, without revealing any information about the other values in the tree that were not disclosed.

A seed tree is formed of $\lambda$-bit seed values, where the left (resp. right) child of a node seed ${ }_{h}$ is the left (resp. right) half of Expand(seed $\| h$ ), where Expand is a pseudorandom generator (PRG) outputting $2 \lambda$ bits and $h$ is a unique identifier for the position of seed in the binary tree. An arbitrary subset of the leaf values can be efficiently revealed by disclosing the values of an appropriate set of internal nodes in the tree.
Informally, a seed tree consists of the following four algorithms. In the random oracle model, the PRG Expand would be modelled with a random oracle $\mathcal{O}$.

- SeedTree(seed $\left.{ }_{\text {root }}, M\right) \rightarrow\left\{\text { leaf }_{i}\right\}_{i \in[M]}$ : On input a root seed seed ${ }_{\text {root }} \in\{0,1\}^{\lambda}$ and an integer $M \in \mathbb{N}$, it constructs a complete binary tree with $M$ leaves by recursively expanding each seed to obtain its children seeds, as above. The output is the list of the $M$ leaf values in the tree.
- ReleaseSeeds $\left(\right.$ seed $\left._{\text {root }}, \mathbf{c}\right) \rightarrow$ seeds $_{\text {internal }}:$ On input a root seed seed ${ }_{\text {root }} \in\{0,1\}^{\lambda}$, and a challenge $\mathbf{c} \in$ $\{0,1\}^{M}$, it outputs the list of seeds seeds ${ }_{\text {internal }}$ that covers all the leaves with index $i$ such that $c_{i}=0$. Here, we say that a set of nodes $D$ covers a set of leaves $S$ if the union of the leaves of the subtrees rooted at each node $v \in D$ is exactly the set $S$.
- RecoverLeaves $\left(\right.$ seeds $\left._{\text {internal }}, \mathbf{c}\right) \rightarrow\left\{\text { leaf }_{i}\right\}_{i \text { s.t. } c_{i}=0}$ : On input a set seeds internal and a challenge $\mathbf{c} \in\{0,1\}^{M}$, it computes and outputs all the leaves of subtrees rooted at seeds in seeds ${ }_{\text {internal }}$. By construction, this is exactly the set $\left\{\text { leaf }_{i}\right\}_{i \text { s.t. } c_{i}=0}$.
- SimulateSeeds $(\mathbf{c}) \rightarrow$ seeds $_{\text {internal }}:$ On input a challenge $\mathbf{c} \in\{0,1\}^{M}$, it computes the set of nodes covering the leaves with index $i$ such that $c_{i}=0$. It then randomly samples a seed from $\{0,1\}^{\lambda}$ for each of these nodes, and finally outputs the set of these seeds as seedsinternal .
By construction, the leaves $\left\{\operatorname{leaf}_{i}\right\}_{i \text { s.t. } c_{i}=0}$ output by SeedTree(seed $\left.{ }_{\text {root }}, M\right)$ are the same as those output by RecoverLeaves(ReleaseSeeds $\left(\right.$ seed $\left.\left._{\text {root }}, \mathbf{c}\right), \mathbf{c}\right)$ for any $\mathbf{c} \in\{0,1\}^{M}$. The last algorithm SimulateSeeds can be used to argue that the seeds associated with all the leaves with index $i$ such that $c_{i}=1$ are indistinguishable from uniformly random values for a recipient that is only given seeds $s_{\text {internal }}$ and $\mathbf{c}$.

## 3 Previous SIDH identification scheme and soundness issue

### 3.1 De Feo-Jao-Plût scheme

Let $p$ be a large prime of the form $\ell_{1}^{e_{1}} \cdot \ell_{2}^{e_{2}} \cdot f \pm 1$, where $\ell_{1}, \ell_{2}$ are small primes. We start with a supersingular elliptic curve $E_{0}$ defined over $\mathbb{F}_{p^{2}}$ with $\# E_{0}\left(\mathbb{F}_{p^{2}}\right)=\left(\ell_{1}^{e_{1}} \ell_{2}^{e_{2}} f\right)^{2}$. The private key is a random point $K_{\phi} \in$ $E_{0}\left(\mathbb{F}_{p^{2}}\right)$ of exact order $\ell_{1}^{e_{1}}$. Define $E_{1}=E_{0} /\left\langle K_{\phi}\right\rangle$ and denote the corresponding $\ell_{1}^{e_{1}}$-isogeny by $\phi: E_{0} \rightarrow$ $E_{1}$.
Let $P_{0}, Q_{0}$ be a basis of the torsion subgroup $E_{0}\left[\ell_{2}^{e_{2}}\right]=\left\langle P_{0}, Q_{0}\right\rangle$. The fixed public parameters are $p p=$ $\left(p, E_{0}, P_{0}, Q_{0}\right)$. The public key is $\left(E_{1}, \phi\left(P_{0}\right), \phi\left(Q_{0}\right)\right)$. The private key is the kernel generator $K_{\phi}$ (equivalently, the isogeny $\phi$ ). The interaction goes as follows:

1. The prover chooses a random primitive $\ell_{2}^{e_{2}}$-torsion point $K_{\psi}$ as $K_{\psi}=[a] P_{0}+[b] Q_{0}$ for some integers $0 \leq a, b<\ell_{2}^{e_{2}}$ not both divisible by $\ell_{2}$. Note that $\phi\left(K_{\psi}\right)=[a] \phi\left(P_{0}\right)+[b] \phi\left(Q_{0}\right)$. The prover defines the curves $E_{2}=E_{0} /\left\langle K_{\psi}\right\rangle$ and $E_{3}=E_{1} /\left\langle\phi\left(K_{\psi}\right)\right\rangle=E_{0} /\left\langle K_{\psi}, K_{\phi}\right\rangle$, and uses Vélu's formulae to compute the following diagram.

The prover sends commitment com $=\left(E_{2}, E_{3}\right)$ to the verifier.
2. The verifier challenges the prover with a random bit chall $\leftarrow\{0,1\}$.
3. If chall $=0$, the prover reveals resp $=(a, b)$ from which $K_{\psi}$ and $\phi\left(K_{\psi}\right)=K_{\psi^{\prime}}$ can be reconstructed.

If chall $=1$, the prover reveals resp $=\left(\psi\left(K_{\phi}\right)=K_{\phi^{\prime}}\right)$.
In both cases, the verifier accepts the proof if the points revealed have the correct order and generate kernels of isogenies between the correct curves. We iterate this process $t$ times to reduce the cheating probability (where $t$ is chosen based on the security parameter $\kappa$ ).
Note that in an honest execution of the proof, we have

$$
\widehat{\psi^{\prime}} \circ \phi^{\prime} \circ \psi=\left[\ell_{2}^{e_{2}}\right] \phi
$$

### 3.2 Issue with soundness proofs for the De Feo-Jao-Plût scheme

A core component of the security proof of the De Feo-Jao-Plut identification scheme is the soundness proof. A proof of soundness was given by multiple previous works [DJP14, YAJ ${ }^{+}$17, GPS20] based on the CSSI problem in Definition 2. A sketch of this soundness proof is as follows:

Suppose $\mathcal{A}$ is an adversary that takes as input the public key and succeeds in the identification protocol (all $t$ iterations) with noticeable probability $\epsilon$. Given a challenge instance ( $\left.E_{0}, E_{1}, R_{2}, S_{2}, \phi\left(R_{2}\right), \phi\left(S_{2}\right)\right)$ for the CSSI problem, we run $\mathcal{A}$ on the tuple $\left(E_{1}, \phi\left(R_{2}\right), \phi\left(S_{2}\right)\right)$ as the public key. In the first round, $\mathcal{A}$ outputs commitments $\left(E_{i, 2}, E_{i, 3}\right)$ for $1 \leq i \leq t$. We then send a challenge $b \in\{0,1\}^{t}$ to $\mathcal{A}$ and, with probability $\epsilon$, $\mathcal{A}$ outputs a response that satisfies the verification algorithm. Now, we use the standard replay technique: Rewind $\mathcal{A}$ to the point where it had output its commitments and then respond with a different challenge
$b^{\prime} \in\{0,1\}^{t}$. With probability $\epsilon, \mathcal{A}$ outputs a valid response. This gives exactly the 2 -special soundness requirement of two valid transcripts with the same commitment but different challenges.

Now, choose some index $i$ such that $b_{i} \neq b_{i}^{\prime}$. We now restrict our focus to the components $\left(E_{2}, E_{3}\right)$ for that index, and the two responses. It means $\mathcal{A}$ sent $E_{2}, E_{3}$ and can answer both challenges $b=0$ and $b=1$ successfully. Hence $\mathcal{A}$ has provided the maps $\psi, \phi^{\prime}, \psi^{\prime}$ in the following diagram.

The argument proceeds as follows: We have an explicit description of an isogeny $\tilde{\phi}=\widehat{\psi^{\prime}} \circ \phi^{\prime} \circ \psi$ from $E_{0}$ to $E_{1}$. The degree of $\tilde{\phi}$ is $\ell_{1}^{e_{1}} \ell_{2}^{2 e_{2}}$. One can determine $\operatorname{ker}(\tilde{\phi}) \cap E_{0}\left[\ell_{1}^{e_{1}}\right]$ by iteratively testing points in $E_{0}\left[\ell_{1}^{j}\right]$ for $j=1,2, \ldots$. Hence, one determines the kernel of $\phi$, as desired.
However, the important issue with this argument which has so far gone unnoticed, is that it assumes ker $(\phi)=$ $\operatorname{ker}(\tilde{\phi}) \cap E_{0}\left[\ell_{1}^{e_{1}}\right]$. This assumption has no basis, and we will provide a simple counterexample to this argument in the following section. While we always recover an isogeny, it may not be $\phi$ at all - it is entirely possible the isogeny we recover does not even have codomain $E_{1}$ so this proof of 2-special soundness is not valid.

### 3.3 Counterexample to soundness

Fix a supersingular curve $E_{0}$ as above. Generate a random $\ell_{2}^{e_{2}}$-torsion point $K_{\psi} \in E_{0}\left(\mathbb{F}_{p^{2}}\right)$ as $K_{\psi}=$ $[a] P_{2}+[b] Q_{2}$ for some integers $0 \leq a, b<\ell_{2}^{e_{2}}$ not both divisible by $\ell_{2}$. Let $\psi: E_{0} \rightarrow E_{2}$ have kernel generated by $K_{\psi}$. Then choose a random isogeny $\phi^{\prime}: E_{2} \rightarrow E_{3}$ of degree $\ell_{1}^{e_{1}}$ with kernel generated by $K_{\phi^{\prime}}$. Then choose a random isogeny $\psi^{\prime}: E_{3} \rightarrow E_{1}$ of degree $\ell_{2}^{e_{2}}$. Choose points $P_{2}^{\prime}, Q_{2}^{\prime} \in E_{1}\left(\mathbb{F}_{p^{2}}\right)$ such that $\operatorname{ker}\left(\widehat{\psi}^{\prime}\right)=\left\langle[a] P_{2}^{\prime}+[b] Q_{2}^{\prime}\right\rangle$. Then publish

$$
\left(E_{0}, E_{1}, P_{2}, Q_{2}, P_{2}^{\prime}, Q_{2}^{\prime}\right)
$$

as a public key. In other words, we have

$$
E_{0} \xrightarrow{\psi} E_{2} \xrightarrow{\phi^{\prime}} E_{3} \xrightarrow{\psi^{\prime}} E_{1}
$$

Now there is no reason to believe that there exists an isogeny from $E_{0}$ to $E_{1}$ of degree $\ell_{1}^{e_{1}}$, yet we can respond to both challenge bits 0 and 1 in a single round of the identification scheme. Pulling back the kernel of $\phi^{\prime}$ via $\psi$ to $E_{0}$ will result in the kernel of an isogeny which, in general, will not have codomain $E_{1}$ (but instead a random other curve). This is because $\psi^{\prime}$ is entirely unrelated to $\psi$ in this case (they are not "parallel"), so we have no SIDH square.

The key observation is that a verifier could be fooled into accepting this public key by a prover who always uses the same curves $\left(E_{2}, E_{3}\right)$ instead of randomly chosen ones. When $b=0$ the prover responds with the pair $(a, b)$ corresponding to the kernel of $\psi$ and $\widehat{\psi}^{\prime}$, and when $b=1$ the prover responds with $K_{\phi^{\prime}}$. The verifier will agree that all responses are correct and will accept the proof.

The reader may immediately have several thoughts:

1. This is not the correct protocol description, since the isogenies $\psi$ and $\psi^{\prime}$ are supposed to be random. The verifier can check if the same commitments $\left(E_{2}, E_{3}\right)$ are always being re-used.
2. This scheme would not be zero-knowledge. If the protocol is repeated many times with the same pair $\left(E_{2}, E_{3}\right)$ then the composition $\psi^{\prime} \circ \phi^{\prime} \circ \psi$ will be revealed to the verifier, leaking an isogeny from $E_{0}$ to $E_{1}$ and therefore allowing the verifier to impersonate the prover in the future.
3. Proving identity (or forging signatures) still requires knowledge of some isogeny from $E_{0}$ to $E_{1}$. So we can rescue the security proof by basing security on the general isogeny problem (Definition 1) instead of the SIDH problem.
4. The SIDH assumption as stated claims that an isogeny from $E_{0}$ to $E_{1}$ of degree $\ell_{1}^{e_{1}}$ exists, and asks to compute it. So surely that prevents the "attack" as well.

In response we say:

1. It is true that the verifier could test if the commitments $\left(E_{2}, E_{3}\right)$ are being re-used, but this has never been stated as a requirement in any of the protocol descriptions. To tweak the verification protocol we need to know how "random" the pairs $\left(E_{2}, E_{3}\right)$ (or, more realistically, the pairs $\left.(a, b)\right)$ need to be.
2. It is true that repeating $\left(E_{2}, E_{3}\right)$ means the protocol is no longer zero knowledge. But soundness and zero-knowledge are independent security properties that are proved separately (and affect different parties: one gives an assurance to the verifier and the other to the prover). Our counterexample is a counterexample to the soundness proof. The fact that the counterexample is not consistent with the proof that the protocol is zero knowledge is irrelevant.
$3-4$. It is true that we could instead base security of the protocol on the general isogeny problem. Interestingly, none of the previous authors chose to do it that way. But some applications may require using the identification/signature protocols to prove that an SIDH public key is well-formed. For such applications we need soundness to be rigorously proved. The issue in the security proofs in the literature is not only that it is implicitly assumed that there is an isogeny of degree $\ell_{1}^{e_{1}}$ between $E_{0}$ and $E_{1}$. The key issue is that it is implicitly assumed that the pullback under $\psi$ of $\operatorname{ker}\left(\phi^{\prime}\right)$ is the kernel of this isogeny. Our counterexample calls these assumptions into question, and shows that the proofs are incorrect as written down.

To make this very clear, consider the soundness proof from De Feo, Jao and Plût DJP14. The following diagram is written within the proof. It implicitly assumes that the horizontal isogeny $\phi^{\prime}$ has kernel given by $\psi(S)$, so that the image curve is $E /\langle S, R\rangle$.

This implicit assumption seems to have been repeated in all subsequent works, such as [YAJ+17] and GPS20.
Note: we conjecture the original scheme to be secure despite the issue with the proof, as long as the commitment $E_{2}, E_{3}$ is not reused every time (point 1. above). This simple check can be added into the original scheme.

Conjecture 1. The De Feo-Jao-Plût identification scheme with $t$ rounds (for appropriately chosen $t$ ) is sound with the following modification: the verifier additionally checks that commitments $\left(E_{2}, E_{3}\right)$ are not reused between rounds (that is, each round uses a different commitment).

We leave proof of this conjecture for future work.
It is not clear whether a similar conjecture may hold to repair the soundness of Urbanik and Jao's scheme UJ20.

## 4 New SIDH identification scheme

Let public parameters $p p=\left(p, E_{0}, P_{0}, Q_{0}\right)$ such that $E_{0}\left(\mathbb{F}_{p^{2}}\right)\left[\ell_{2}^{e_{2}}\right]=\left\langle P_{0}, Q_{0}\right\rangle$. As before, suppose a user has a secret isogeny $\phi: E_{0} \rightarrow E_{1}$ with kernel $\operatorname{ker} \phi=K_{\phi}$. Without loss of generality we assume that the secret isogeny has degree $\ell_{1}^{e_{1}}$.

### 4.1 On SIDH point validation

At the heart of the adaptive attack is the problem that, given a public key $\left(E_{1}, P, Q\right)$, we cannot validate that $P, Q$ are indeed the correct images of basis points $P_{0}, Q_{0}$ under the secret isogeny $\phi$. The best we can do is to check they are indeed a basis of the correct order, and use the Weil pairing check from Galbraith et al. GPST16:

$$
e_{N}(P, Q)=e_{N}\left(P_{0}, Q_{0}\right)^{\operatorname{deg} \phi}
$$

Unfortunately this holds for many different choices of basis points, hence why this check is not enough to protect against the GPST attack.
For example, note that there are $\ell_{2}^{4 e_{2}-3} \cdot\left(\ell^{2}-1\right)^{2} /(\ell+1)$ different possible choices for ordered linearly independent basis $P, Q$ of the correct order - this is because there are $\ell_{2}^{2 e_{2}}-\ell_{2}^{2\left(e_{2}-1\right)}$ points of the correct order, and the independence between $P$ and $Q$ introduces a factor of $\ell_{2} /\left(\ell_{2}+1\right)$. Yet, only $\left(\ell_{2}+1\right) \cdot \ell_{2}^{e_{2}-1}$ different isogenies of order $\ell_{2}^{e_{2}}$ exist. Hence, for any particular choice of coefficients for the basis points, there must be a great deal of overlap in the kernels they generate. For example, if $\ell_{2}=3$, we would have $16 \cdot 3^{3 e_{2}-2}$ different choices of points for each kernel.

Obviously, many of these choices will not satisfy the Weil pairing check. However, the codomain of $e_{\ell_{2}^{e_{2}}}$ has order $\ell_{2}^{e_{2}}$, which is much smaller than the number of choices of points.
As shown by Galbraith and Vercauteren GV18, Thormarker Tho17, and Urbanik and Jao UJ18, being able to solve the decisional problem of whether there exists a secret degree $\ell^{e}$ isogeny corresponding to a given SIDH public key is actually as hard as solving the corresponding computational problem, so key validation is fundamentally difficult. We propose a new assumption which reduces in the same way to a computational isogeny-finding problem, which will be useful for the proof of zero-knowledge in the next section.

Definition 6 (Decisional Supersingular Isogeny Point Image (DSIPI) problem). Suppose there exists $\phi$ : $E_{0} \rightarrow E_{1}$ such that $\operatorname{deg} \phi=\ell_{1}^{e_{1}}$. Let $P_{0}, Q_{0}$ be a basis for the $\ell_{2}^{e_{2}}$ torsion subgroup $E_{0}\left[\ell_{2}^{e_{2}}\right]$, let $K \in E_{0}$ be a point of order $\ell_{2}^{e_{2}}$, and let $E_{2} \cong E_{0} /\langle K\rangle$ and $E_{3} \cong E_{1} /\langle\phi(K)\rangle$.
Given $e_{1}, E_{0}, E_{1}, P_{0}, Q_{0}, \phi\left(P_{0}\right), \phi\left(Q_{0}\right)$, as well as $K, \phi(K)$, a random basis $P_{2}, Q_{2}$ of $E_{2}\left[\ell_{2}^{e_{2}}\right]$, and a basis $P_{3}, Q_{3}$ of $E_{3}\left[\ell_{2}^{e_{2}}\right]$, such that

$$
e_{\ell_{2}^{e_{2}}}\left(P_{2}, Q_{2}\right)=e_{\ell_{2}^{e_{2}}}\left(P_{3}, Q_{3}\right)^{\ell_{1}^{e_{1}}}
$$

Decide whether $P_{3}, Q_{3}=\phi^{\prime}\left(P_{2}\right), \phi^{\prime}\left(Q_{2}\right)$ for $\phi^{\prime}: E_{2} \rightarrow E_{3}$ of degree $\ell_{1}^{e_{1}}$.
Unlike the usual DSIDH problem (Definition 3), the provision of $K$ and $\phi(K)$ ensures that there does indeed exist an isogeny of degree $\ell_{1}^{e_{1}}$ between $E_{2}$ and $E_{3}$. The problem then is to simply decide whether $P_{3}, Q_{3}$ are the images of $P_{2}, Q_{2}$ under this isogeny. We claim that if $P_{2}, Q_{2}$ is a random basis (independent of all the other information given) then because $\phi$ is hidden, and if the Weil pairing check holds, the images of $P_{2}, Q_{2}$ should be indistinguishable from any other basis.

The DSIPI problem reduces to a computational isogeny problem in a very similar way to how the DSIDH problem does. To see why, suppose we have a distinguisher $\mathcal{B}$ against the DSIPI problem, which takes an instance $\left(e_{1}, E_{0}, E_{1}, P_{0}, Q_{0}, \phi\left(P_{0}\right), \phi\left(Q_{0}\right), K, \phi(K), P_{2}, Q_{2}, P_{3}, Q_{3}\right)$. There are $\ell_{1}+1$ different $\ell_{1}$-isogenies from $E_{1}$ and from $E_{3}$, so we test each of the $\left(\ell_{1}+1\right)^{2}$ combinations $\left(\varphi: E_{1} \rightarrow E_{1}^{\prime}, \varphi^{\prime}: E_{3} \rightarrow E_{3}^{\prime}\right)$. Let $u$ be
such that $u \ell_{1} \equiv 1\left(\bmod \ell_{2}^{e_{2}}\right)$. Let $P_{3}^{\prime}=[u] \varphi^{\prime}\left(P_{3}\right)$ and similarly for $Q_{3}^{\prime}$, and let $P_{1}^{\prime}=[u] \varphi\left(\phi\left(P_{0}\right)\right)$ and similarly for $Q_{0}$ and $K$. Now run $\mathcal{B}\left(e_{1}-1, E_{0}, E_{1}^{\prime}, P_{0}, Q_{0}, P_{1}^{\prime}, Q_{1}^{\prime}, K, K^{\prime}, P_{2}, Q_{2}, P_{3}^{\prime}, Q_{3}^{\prime}\right)$, and one step of both $\phi$ and $\phi^{\prime}$ will be learned when $\mathcal{B}$ returns true. The following diagram may be helpful in fixing the notation:

This process can be repeated until all the $\ell_{1}$-isogeny steps of $\phi$ and $\phi^{\prime}$ are learned (the dashed arrow in the diagram). Thus, assuming this computational problem is hard, so too is the DSIPI problem. SIDH fundamentally assumes that providing the action of a secret isogeny $\phi$ on a basis for a coprime torsion subgroup does not leak the secret isogeny itself, so in our setting, doing the same for $\phi^{\prime}$ on a totally independent basis should also not leak either $\phi^{\prime}$ or $\phi$.

### 4.2 Scheme

We propose a new sigma protocol to prove knowledge of this isogeny given the public key $\left(E_{1}, P_{1}=\right.$ $\left.\phi\left(P_{0}\right), Q_{1}=\phi\left(Q_{0}\right)\right)$. The protocol is presented in Figure 3 . IsogenyFromKernel () is a function taking a kernel point and outputting an isogeny and codomain curve with said kernel. CanonicalBasis() is a function taking a curve and outputting a canonical $\ell_{2}^{e_{2}}$ torsion basis on the given curve. Figure 2 shows the commutative diagram of the sigma protocol.

Intuitively, the identification scheme follows 3.1, with a single bit challenge - if the challenge is 0 , we reveal the vertical isogenies $\psi, \psi^{\prime}$, while if the challenge is 1 , we reveal the horizontal $\phi^{\prime}$. The difference is the introduction of additional points on $E_{3}$ to the commitment, which force $\psi, \psi^{\prime}$ to be, in some sense "compatible" or "parallel". This restriction allows the proof of 2 -special soundness to work.

We then repeat the identification scheme $t$ times in parallel (where $t$ is chosen based on the security parameter $\kappa$ ) and set com to be the concatenation of all individual $\left[\operatorname{com}_{i}\right]_{i \in[t]}$ for each iteration $i$, chall $=\left[\text { chall }_{i}\right]_{i \in[t]}$ and resp $=\left[\text { resp }_{i}\right]_{i \in[t]}$.

Figure 2: Commutative diagram of SIDH identification scheme
Note: Verification requires checking that there exists integers $c, d$ generating the kernels of dual isogenies $\widehat{\psi}, \widehat{\psi^{\prime}}$. This computation can be offloaded to the prover by requiring them to send the correct integers. In

## round 1

$a, b \leftarrow \mathbb{Z} / \ell_{2}^{e_{2}} \mathbb{Z} \quad \triangleright$ N.B. we can use equivalent keys (Rem. 11) for compactness WLOG
$K_{\psi}=[a] P_{0}+[b] Q_{0} \in E_{0}$
$K_{\psi^{\prime}}=\phi\left(K_{\psi}\right)=[a] \phi\left(P_{0}\right)+[b] \phi\left(Q_{0}\right) \in E_{1}$
$\psi, E_{2} \leftarrow$ IsogenyFromKernel $\left(K_{\psi}\right)$
$P_{2}, Q_{2} \leftarrow$ CanonicalBasis $\left(E_{2}\right)$
$K_{\phi^{\prime}} \leftarrow \psi\left(K_{\phi}\right) \in E_{2}$
$\phi^{\prime}, E_{3} \leftarrow$ IsogenyFromKernel $\left(K_{\phi^{\prime}}\right)$
$P_{3}, Q_{3} \leftarrow \phi^{\prime}\left(P_{2}\right), \phi^{\prime}\left(Q_{2}\right) \in E_{3}$
Prover sends com $=\left(E_{2}, E_{3}, P_{3}, Q_{3}\right)$ to Verifier.

## round 2

$c \leftarrow\{0,1\}$
Verifier sends chall $\leftarrow c$ to Prover.

## round 3

```
\(c \leftarrow\) chall
```

if $c=1$ then
resp $\leftarrow K_{\phi^{\prime}}$
else
resp $\leftarrow(a, b)$
Prover sends resp to Verifier.

## Verification

```
\(\left(E_{2}, E_{3}, P_{3}, Q_{3}, c\right) \leftarrow(\) com, chall \()\)
if \(c=1\) then
    \(K_{\phi^{\prime}} \leftarrow\) resp
    Check \(K_{\phi^{\prime}}\) has order \(\ell_{1}^{e_{1}}\) and lies on \(E_{2}\), otherwise output reject
    \(P_{2}, Q_{2} \leftarrow\) CanonicalBasis \(\left(E_{2}\right)\)
    \(\phi^{\prime}, E_{3}^{\prime} \leftarrow\) IsogenyFromKernel \(\left(K_{\phi^{\prime}}\right)\)
    Verify \(E_{3}=E_{3}^{\prime}\) and \(P_{3}, Q_{3}=\phi^{\prime}\left(P_{2}\right), \phi^{\prime}\left(Q_{2}\right)\), otherwise output reject
    Verifier outputs accept
else
    \((a, b) \leftarrow\) resp
    Check that \(P_{1}, Q_{1} \in E_{1}\)
    \(K_{\psi}, K_{\psi^{\prime}}=[a] P_{i}+[b] Q_{i}\) for \(i=0,1\) resp.
    Check \(K_{\psi}\) and \(K_{\psi^{\prime}}\) have order \(\ell_{2}^{e_{2}}\), otherwise output reject
    \(\psi, E_{2}^{\prime} \leftarrow\) IsogenyFromKernel \(\left(K_{\psi}\right)\)
    \(\psi^{\prime}, E_{3}^{\prime} \leftarrow\) IsogenyFromKernel \(\left(K_{\psi^{\prime}}\right)\)
    Check \(E_{2}=E_{2}^{\prime}\) and \(E_{3}=E_{3}^{\prime}\)
    \(P_{2}, Q_{2} \leftarrow\) CanonicalBasis \(\left(E_{2}\right)\)
    Check there exists \(c, d \in \mathbb{Z} / \ell_{2}^{e_{2}} \mathbb{Z}\) such that, simultaneously,
    \(-\operatorname{ker} \widehat{\psi}=[c] P_{2}+[d] Q_{2}\)
    \(-\operatorname{ker} \widehat{\psi^{\prime}}=[c] P_{3}+[d] Q_{3}\)
```

    Verifier outputs accept if the preceding conditions hold, otherwise reject
    Figure 3: One iteration of the sigma protocol for our new SIDH identification scheme. The public parameters are $p p=\left(p, \ell_{1}, \ell_{2}, e_{1}, e_{2}, E_{0}, P_{0}, Q_{0}\right)$. The public key is $\left(E_{1}, P_{1}, Q_{1}\right)$, and the corresponding secret isogeny is $\phi$.
fact, these integers uniquely determine the horizontal isogenies so they could be sent as resp by the prover without needing $K_{\psi}, K_{\psi^{\prime}}$, but this would require more computation to verify.
Remark 2. There are certainly improvements that can be made to improve efficiency and compress the size of signatures, but these are standard and we will not explore them here. For example, in practice the commitment information ( $E_{3}, P_{3}, Q_{3}$ ) would be replaced with a triplet of $x$-coordinates, as in SIKE [ACC ${ }^{+} 17$.
Theorem 1. The sigma protocol in Figure 3 for relation

$$
\mathcal{R}_{\text {weakSIDH }}=\left\{\left(\left(E_{1}, P_{1}, Q_{1}\right), \phi\right) \mid \phi: E_{0} \rightarrow E_{1}, \operatorname{deg} \phi=\ell_{1}^{e_{1}}\right\}
$$

is complete, 2-special sound, and computationally zero knowledge assuming the DSIPI and DSSP problems are hard. Repeated with $\kappa$ iterations, it is thus a Proof of Knowledge for $\mathcal{R}_{\text {weakSIDH }}$ with knowledge error $2^{-\kappa}$.

Proof. We prove the three properties of Theorem 1 separately below.

Completeness: It is clear that following the protocol honestly will result in an accepting transcript.
2-special soundness: Suppose we obtain two accepting transcripts (com, chall, resp) and (com, chall', resp') for statement $X$, with chall $\neq$ chall'. Consider one of the $t$ rounds $i$ where the challenge bit chall ${ }_{i}$ differs from chall ${ }_{i}^{\prime}$. The secret isogeny corresponding to the public key ( $E_{1}, P_{1}, Q_{1}$ ) can be recovered as follows, hence Extract can extract a valid witness for the statement $X$ such that $(X, W) \in \mathcal{R}_{\text {weakSIDH }}$.

Without loss of generality, suppose chall ${ }_{i}=0$ and chall $i_{i}^{\prime}=1$. Then recover $(a, b)$ and thus $\left(K_{\psi}, K_{\psi^{\prime}}\right)$ from $\operatorname{resp}_{i}$, and $K_{\phi^{\prime}}$ from resp ${ }_{i}^{\prime}$. Compute the dual isogeny $\widehat{\psi}$ and use this to pull the kernel $K_{\phi^{\prime}}$ back to $E_{0}$ (this works because the degrees of $K_{\phi^{\prime}}$ and $\widehat{\psi}$ are coprime). Let $\varphi$ be the isogeny with kernel $\left\langle K_{\varphi}=\widehat{\psi}\left(K_{\phi^{\prime}}\right)\right\rangle$, so that $\varphi: E_{0} \rightarrow E_{0} /\left\langle K_{\varphi}\right\rangle$.

We first demonstrate that $E_{0} /\left\langle K_{\varphi}\right\rangle \cong E_{1}$. This follows by considering the diagram of Figure 2 as an SIDH square starting from base curve $E_{2}$. We have that $E_{1} \cong E_{2} /\left\langle K_{\phi^{\prime}}, G\right\rangle$ for subgroup $G$ of order $\ell_{2}^{e_{2}}$ such that $\phi^{\prime}(G)=\operatorname{ker} \widehat{\psi^{\prime}}$. However, note that the restriction on the kernels of $\widehat{\psi}, \widehat{\psi^{\prime}}$ force ker $\widehat{\psi^{\prime}}=\phi^{\prime}(\operatorname{ker} \widehat{\psi})$ so $G=K_{\widehat{\psi}}$. Thus, $E_{0} \cong E_{2} /\left\langle G=K_{\widehat{\psi}}\right\rangle$ and commutativity implies $\varphi$ exists and has the correct degree, and $E_{1} \cong E_{0} /\left\langle K_{\varphi}\right\rangle$ as required. A perhaps simpler argument is that $\hat{\psi}^{\prime} \circ \phi^{\prime} \circ \psi$ is an isogeny from $E_{0}$ to $E_{1}$ that kills the entire $\ell_{2}^{e_{2}}$ torsion $E_{0}\left[\ell_{2}^{e_{2}}\right]$ so must factor through $\left[\ell_{2}^{e_{2}}\right]$. Hence there is a degree $\ell_{1}^{e_{1}}$ isogeny from $E_{0}$ to $E_{1}$.

Thus we recover an isogeny $\varphi$ of correct degree $\ell_{1}^{e_{1}}$ such that the codomain is isomorphic to $E_{1}$. This shows the protocol is 2 -special sound, and that it is a Proof of Knowledge of an isogeny corresponding to the given public key curve (but says nothing about the points in the public key - hence the weakSIDH relation).

Zero-knowledge: Proof of ZK follows as in DJP14. Let $V^{*}$ be a cheating verifier, which shall be used as a black box by the simulator Sim. We shall show that Sim can generate a valid transcript for $t$ iterations of the protocol. At each step, Sim makes a guess what the next challenge bit chall will be, and then proceeds as follows.

- If chall $=0$, Sim simulates as per the honest protocol by choosing $a, b \leftarrow \mathbb{Z} / \ell_{2}^{e_{2}} \mathbb{Z}$ and computing the two vertical isogenies $\psi: E_{0} \rightarrow E_{2}, \psi^{\prime}: E_{1} \rightarrow E_{3}$ from kernel generators $K_{\psi}=[a] P_{0}+[b] Q_{0}$ and $K_{\psi^{\prime}}=$ $[a] P_{1}+[b] Q_{1}$. The simulator then computes the corresponding dual isogenies and the canonical basis $P_{2}, Q_{2} \leftarrow$ CanonicalBasis $\left(E_{2}\right)$. It writes $K_{\widehat{\psi}}$ in terms of this basis as $[c] P_{2}+[d] Q_{2}$, then chooses a torsion basis on $E_{3}$ as $P_{3}, Q_{3} \in E_{3}$ such that $\left\langle K_{\widehat{\psi^{\prime}}}\right\rangle=\left\langle[c] P_{3}+[d] Q_{3}\right\rangle$, where $e_{\ell_{2}^{e_{2}}}\left(P_{3}, Q_{3}\right)=e_{\ell_{2}^{e_{2}}}\left(P_{0}, Q_{0}\right)^{\ell_{1}^{e_{1}}}$ (see Remark 3). Finally, Sim sets the commitment to com $=\left(E_{2}, E_{3}, P_{3}, Q_{3}\right)$ and the response to resp $=(a, b)$ as required.
- If chall $=1$, the simulator chooses a random curve $E_{2}$ and a random point point $K \in E_{2}$ of correct order $\ell_{1}^{e_{1}}$. Then compute the isogeny $\phi^{\prime}: E_{2} \rightarrow E_{3}$ with kernel $K$ with IsogenyFromKernel. Finally generate a canonical basis $P_{2}, Q_{2} \leftarrow$ CanonicalBasis $\left(E_{2}\right)$ and compute $P_{3}, Q_{3} \leftarrow \phi^{\prime}\left(P_{2}\right), \phi^{\prime}\left(Q_{2}\right)$ and set the commitment to $\left(E_{2}, E_{3}, P_{3}, Q_{3}\right)$.
After providing com to $V^{*}$, if the challenge $V^{*}$ outputs is not the same as Sim's guess, simply discard that iteration and run again. Sim stops whenever $V^{*}$ rejects or after $t$ successful rounds. Suppose the probability of $V^{*}$ not choosing the same bit as Sim's guess is noticeably different from $1 / 2$. Then $V^{*}$ can be used as a distinguisher for the DSSP problem (in fact, an even harder problem than the DSSP, as we point out below). So the probability Sim guesses correctly each round is exponentially close to $1 / 2$ if the DSSP problem is hard. Thus Sim will run in polynomial time.

To prove indistinguishability of simulated transcripts from true interactions of a prover $P$ with $V^{*}$, it is enough to show that one round of the sigma protocol is indistinguishable (by the hybrid technique of Goldreich et al. GMW91).
When chall $=0$, the outputs of the simulator are identical to those generated according to the protocol, except for the points $P_{3}, Q_{3}$. However, because the points $P_{3}, Q_{3}$ are chosen by the simulator to pass the Weil pairing check, by the DSIPI (Definition 6) assumption, these points chosen by the simulator are indistinguishable from the honest images of the canonical basis. Hence, the distributions are computationally indistinguishable assuming the DSIPI problem is hard.

When chall $=1$, we consider the distribution of $\left(E_{2}, E_{3}, \phi^{\prime}\right)$. While this distribution is not correct a priori, the DSSP computational assumption in Definition 4 implies it is computationally hard to distinguish the simulation from the real game (as in the proof in GPS20). Because providing the action of $\phi^{\prime}$ on canonical basis $P_{2}, Q_{2} \in E_{2}$ cannot reveal more information than providing $\phi^{\prime}$ itself, the distribution of $\left(E_{2}, E_{3}, P_{3}, Q_{3}\right)$ must also be indistinguishable between simulation and real transcripts.

Hence the scheme has computational zero knowledge assuming the DSSP and DSIPI problems are hard.
Remark 3 (Computing a compatible basis.). In the proof of ZK , we require choosing a basis $P_{3}, Q_{3}$ for the torsion $E_{3}\left[\ell_{2}^{e_{2}}\right]$ such that for a fixed kernel $\langle K\rangle<E_{3}\left[\ell_{2}^{e_{2}}\right]$ and fixed integers $c, d,\langle K\rangle=\left\langle[c] P_{3}+[d] Q_{3}\right\rangle$. This can be done efficiently due to the ease of computing discrete logarithms when the field order is very smooth Tes99. For example, simply choose any basis $P^{\prime}, Q^{\prime}$ and write $K=\left[c^{\prime}\right] P^{\prime}+\left[d^{\prime}\right] Q^{\prime}$ by solving discrete logarithms with respect to $P^{\prime}, Q^{\prime}$. The shift between bases $P^{\prime}, Q^{\prime}$ and $P_{3}=[w] P^{\prime}+[x] Q^{\prime}, Q_{3}=[y] P^{\prime}+[z] Q^{\prime}$ must be linear, so we can write $K=[c] P_{3}+[d] Q_{3}=[c w+d y] P^{\prime}+[c x+d z] Q^{\prime}$. Then simply solve the linear system $c w+d y=c^{\prime}, c x+d z=d^{\prime}$ for $w, x, y, z$ and compute $P_{3}, Q_{3}$. To ensure the Weil pairing check passes, an extra scalar $\theta$ can be multiplied by $P_{3}$ and $Q_{3}$, because as long as $\theta$ is coprime to $\ell_{2}^{e_{2}}$, $\langle K\rangle=\langle[\theta] K\rangle=\left\langle[c] \theta P_{3}+[d] \theta Q_{3}\right\rangle$. If $P^{\prime}, Q^{\prime}$ are chosen such that $e_{\ell_{2}^{e_{2}}}\left(P^{\prime}, Q^{\prime}\right)=e_{\ell_{2}^{e_{2}}}(P, Q)^{e_{1} e_{1}}$, then $\theta$ should be chosen as $\theta^{2}=(w z-x y)^{-1}$. If $(w z-x y)$ is not invertible, the simulator can simply repeat the choice of $P^{\prime}, Q^{\prime}$ and try again.

## 5 Correctness of the points in an SIDH public key

We have shown in Section 4 that successful completion of the new sigma protocol indeed proves knowledge of a degree $\ell_{1}^{e_{1}}$ isogeny from $E_{0}$ to $E_{1}$ (as per the relation $\mathcal{R}_{\text {weakSIDH }}$ in Theorem 1). However, an SIDH public key also consists of the two torsion points, and these points are the cause of issues such as the adaptive attack GPST16, as discussed in Section 2.2 . In this section, we show that the choice of points $P_{1}, Q_{1}$ by the adversary is severely restricted if they must keep them consistent with "random enough" values of $a, b$ (i.e., random choices of $\psi$ ) - preventing adaptive attacks entirely. This gives the following stronger SIDH relation:

$$
\mathcal{R}_{\mathrm{SIDH}}=\left\{\left(\left(E_{1}, P_{1}, Q_{1}\right), \phi\right) \left\lvert\, \begin{array}{c|c}
\phi: E_{0} \rightarrow E_{1}, \operatorname{deg} \phi=\ell_{1}^{e_{1}} \wedge \\
P_{1}=[\lambda] \phi\left(P_{0}\right) \wedge \\
Q_{1}=[\lambda] \phi\left(Q_{0}\right) \\
\lambda \in \pm 1
\end{array}\right.\right\}
$$

We have that $\operatorname{ker} \psi=\left\langle K_{\psi}\right\rangle=\left\langle[a] P_{0}+[b] Q_{0}\right\rangle$ for the fixed points $P_{0}, Q_{0}$. This choice of $\psi$ also fixes $\widehat{\psi}$. Now, $\operatorname{ker} \widehat{\psi^{\prime}}=\phi^{\prime}(\operatorname{ker} \widehat{\psi})$ as before, so $\widehat{\psi^{\prime}}$ is also fixed, and by extension $\psi^{\prime}$. Finally then, to ensure verification succeeds, the adversary must choose $P^{\prime}, Q^{\prime} \in E_{1}$ such that $\left\langle[a] P^{\prime}+[b] Q^{\prime}\right\rangle=\left\langle K_{\psi^{\prime}}\right\rangle$ for the same $a, b$ as before. For a single choice of $a, b$, there are many ways to decompose ker $\psi^{\prime}$ in terms of two basis points. The key observation though, is that once these points have been fixed in the first iteration of the sigma protocol, all future iterations must use the same two points, but answer with different $(a, b)$ values. If the verifier checks that these $(a, b)$ values are "random enough" whenever they are revealed (challenge bit 0 ), the prover is restricted in their choice of points as we will see below.
So, as stated above, the prover is in a position where they have a fixed kernel $\left\langle K_{\psi^{\prime}}\right\rangle$. Obviously, the "honest" behaviour will give kernel generator $K_{\psi^{\prime}}=[a] \phi\left(P_{0}\right)+[b] \phi\left(Q_{0}\right)$. Two generators generate the same kernel if and only if they are (invertible) scalar multiples of each other. Hence, we consider the case where the adversary wishes to decompose any arbitrary kernel generator $K^{\prime}$ such that $[\lambda] K^{\prime}=K_{\psi^{\prime}}$ in terms of $a, b$, that is, $[a] \phi\left(P_{0}\right)+[b] \phi\left(Q_{0}\right)=[a][\lambda] P^{\prime}+[b][\lambda] Q^{\prime}$. For ease of notation, let $P=\phi\left(P_{0}\right), Q=\phi\left(Q_{0}\right)$.

Because both $P, Q$ and $P^{\prime}, Q^{\prime}$ are bases of the same torsion subgroup, we can represent $P^{\prime}, Q^{\prime}$ in terms of $P, Q$ with a change-of-basis matrix. This matrix must be invertible, so $c f-d e$ must be invertible modulo $\ell_{2}^{e_{2}}$.

$$
\binom{P^{\prime}}{Q^{\prime}}=\left(\begin{array}{ll}
c & d  \tag{1}\\
e & f
\end{array}\right) \cdot\binom{P}{Q}
$$

Now because $P$ and $Q$ are linearly independent, we can match coefficients (modulo the order of the generators) and obtain the following two congruences:

$$
\begin{aligned}
a & \equiv a \lambda c+b \lambda e \quad\left(\bmod \ell_{2}^{e_{2}}\right) \\
b & \equiv a \lambda d+b \lambda f \quad\left(\bmod \ell_{2}^{e_{2}}\right)
\end{aligned}
$$

Giving:

$$
\begin{align*}
& 0 \equiv a(\lambda c-1)+b \lambda e \quad\left(\bmod \ell_{2}^{e_{2}}\right)  \tag{2}\\
& 0 \equiv a \lambda d+b(\lambda f-1) \quad\left(\bmod \ell_{2}^{e_{2}}\right) \tag{3}
\end{align*}
$$

Because $P^{\prime}, Q^{\prime}$ are published by the prover before beginning the protocol, $c, d, e, f$ are all fixed. We now add the restriction that the verifier confirms the $a, b$ 's cover the following three congruency classes modulo $\ell_{2}$ (note that at least one of $a, b$ must not be divisible by $\ell_{2}$ for the kernel to have the correct order):

$$
\begin{array}{rr}
a \equiv 0, b \not \equiv 0 & \left(\bmod \ell_{2}\right) \\
a \not \equiv 0, b \equiv 0 & \left(\bmod \ell_{2}\right) \\
a, b \not \equiv 0 & \left(\bmod \ell_{2}\right)
\end{array}
$$

For ease of notation, we will denote these three cases as $(0, \star),(\star, 0)$, and $(\star, \star)$ respectively. It is clearly implied that $\ell_{2} \nmid \star$.

From here forward, for ease of notation, we will treat all values modulo $\ell_{2}^{e_{2}}$ as integers in the range $0, \ldots, \ell_{2}^{e_{2}}-$ 1. If the prover convinces the verifier that with overwhelming probability (in the security parameter $\kappa$ ) they can answer queries using all three classes of $a, b$ above, then it must be the case that $e=d=0$ and $c=f$ invertible. This indeed proves that the points $P^{\prime}, Q^{\prime}$ are simply an invertible scalar multiple of the original points $P^{\prime}=[\lambda] P, Q^{\prime}=[\lambda] Q$. This is sufficient to ensure there is no possibility of an adaptive attack being performed. In fact, using the Weil pairing check from Galbraith et al. GPST16] as well, we can force the only choices for this scalar to be $\lambda= \pm 1$ (but we don't need this extra restriction so we won't discuss this further).

To set some notation, we use $\ell^{n} \| x$ to denote that $\ell^{n}$ divides $x$, but $\ell^{n+1}$ does not divide $x$. That is, $\ell^{n}$ is the highest power of $\ell$ dividing $x$. In this case, we say $\ell^{n}$ exactly divides $x$.
Theorem 2. For a fixed security parameter $\kappa$ and SIDH public key $(E, P, Q)$, if the prover is able to successfully complete $3 \kappa$ iterations of the identification scheme sigma protocol in Figure 3 as follows:

- $\kappa$ iterations where the prover uses non-repeating challenges $(a, b)$ for $a, b \not \equiv 0\left(\bmod \ell_{2}\right)-c a s e(\star, \star)$,
- $\kappa$ iterations where the prover uses non-repeating challenges $(a, b)$ for $a \not \equiv 0, b \equiv 0\left(\bmod \ell_{2}\right)$ - case $(\star, 0)$, and
- $\kappa$ iterations where the prover uses non-repeating challenges $(a, b)$ for $a \equiv 0, b \not \equiv 0\left(\bmod \ell_{2}\right)$ - case ( $0, \star$ )
then with probability $1-2^{-\kappa}$ the points $P, Q$ are of the form $[\lambda] \phi\left(P_{0}\right),[\lambda] \phi\left(Q_{0}\right)$ for some invertible scalar $\lambda$ (where $\phi$ is a secret $\ell_{1}^{e_{1}}$-isogeny $E_{0} \rightarrow E$ ).

Proof. We fix $c, d, e, f$ and suppose the prover is able to commit to and successfully answer challenges for $(a, b)$ tuples in all three of the classes above.
If $a \equiv 0, b \not \equiv 0\left(\bmod \ell_{2}\right)$, then Equation 2 implies that $e \equiv 0\left(\bmod \ell_{2}\right)$, while Equation 3 requires $f \not \equiv 0$ $\left(\bmod \ell_{2}\right)$. Similarly, if Equations 2 and 3 are able to be satisfied by $a, b$ where $a \not \equiv 0, b \equiv 0\left(\bmod \ell_{2}\right)$, we get that $d \equiv 0\left(\bmod \ell_{2}\right)$ and $c \not \equiv 0\left(\bmod \ell_{2}\right)$.

In the simplest case, $e=d=0$. Requiring Equations 2 and 3 to have solutions of the form $(\star, \star)$ (i.e. $a, b \not \equiv 0$ $\left.\left(\bmod \ell_{2}\right)\right)$ immediately implies that $\lambda c-1 \equiv \lambda f-1 \equiv 0\left(\bmod \ell_{2}^{e_{2}}\right)$. Hence, $c=f$. This case is the "honest prover" scenario where the points $P^{\prime}, Q^{\prime}$ the prover provides in the public key are the same as the correct image points $\phi\left(P_{0}\right), \phi\left(Q_{0}\right)$ under the prover's secret isogeny, up to (co-prime) scalar multiple.

It remains to show, then, that being able to satisfy Equations 2 and 3 with $(a, b)$ pairs across all three of the equivalence classes above force $e=d=0$ - that they cannot be non-zero multiples of $\ell_{2}$. We therefore proceed with a proof by contradiction. Let

$$
\begin{aligned}
& d=d^{\prime} \ell_{2}^{g} \\
& e=e^{\prime} \ell_{2}^{h}
\end{aligned}
$$

where $g, h$ are the greatest powers of $\ell_{2}$ dividing $d, e$ (respectively infinite if $d$ or $e$ is 0 ). Without loss of generality, we can assume that $h \geq g$, because otherwise we can swap the variables $(a, c, e) \leftrightarrow(b, f, d)$. Because we assume that at least one of $e, d$ are non-zero, then this convention implies $d$ (and so too $d^{\prime}$ ) is non-zero, while $e$ (and $e^{\prime}$ ) may or may not be zero. Note that by definition, $\ell_{2} \nmid d^{\prime}$ and if $e^{\prime} \neq 0$, then $\ell_{2} \nmid e^{\prime}$.

If $(a, b)$ tuples of the form $(a, b) \equiv(\star, \star)\left(\bmod \ell_{2}\right)$ are able to satisfy Equation 3 , then

$$
\ell_{2}^{g} \| 1-\lambda f
$$

By considering Equation 2, we also get that

$$
\ell_{2}^{h} \mid 1-\lambda c
$$

(if $e \neq 0$ this divisibility is exact, while if $e=0,1-\lambda c$ must also be 0 ). Because $g \leq h$, clearly $\ell_{2}^{g} \mid 1-\lambda c$. Then,

$$
\begin{aligned}
& 1-\lambda f \equiv 0 \quad\left(\bmod \ell_{2}^{g}\right) \\
& 1-\lambda c \equiv 0 \quad\left(\bmod \ell_{2}^{g}\right) \\
& (1-\lambda f)-(1-\lambda c) \equiv 0 \quad\left(\bmod \ell_{2}^{g}\right) \\
& \lambda f \equiv \lambda c \quad\left(\bmod \ell_{2}^{g}\right)
\end{aligned}
$$

so we have that $c \equiv f\left(\bmod \ell_{2}^{g}\right)$.
Now suppose Equations 2 and 3 can be satisfied by $(a, b) \equiv(\star, 0)\left(\bmod \ell_{2}\right)$ as well. Because $\ell_{2} \nmid a \lambda d^{\prime}$, Equation 3 gives:

$$
\begin{equation*}
\ell_{2}^{g} \| b\left(1-\lambda^{\prime} f\right) \tag{4}
\end{equation*}
$$

We also obtain from Equation 2 that:

$$
\ell_{2}^{h} \mid 1-\lambda^{\prime} c
$$

From this, using the fact that $c \equiv f\left(\bmod \ell_{2}^{g}\right)$ from the $(\star, \star)$ case, and that $g \leq h$, we get

$$
\begin{array}{r}
\ell_{2}^{g} \mid 1-\lambda^{\prime} c \\
\ell_{2}^{g} \mid 1-\lambda^{\prime} c-\lambda(f-c) \\
\ell_{2}^{g} \mid 1-\lambda^{\prime} f
\end{array}
$$

However, if $\ell_{2}^{g} \mid 1-\lambda^{\prime} f$ and $\ell_{2} \mid b$, then

$$
\ell_{2}^{g+1} \mid b\left(1-\lambda^{\prime} f\right)
$$

Which contradicts Equation 4 by definition of exact divisibility.
Thus, if $(a, b)$ tuples of both forms $(\star, \star)$ and $(\star, 0)$ modulo $\ell_{2}$ are able to satisfy Equations 2 and 3 then necessarily $d=0$ (and by extension of our assumption $h \geq g, e=0$ ). To remove the assumption that $h \geq g$, we simply require that tuples of the form $(0, \star)$ are also satisfiable (due to the $(a, c, e) \leftrightarrow(b, f, d)$ variable swap). This concludes the proof. The probability given in the theorem follows trivially from the fact that, as in the original SIDH identification scheme, $\kappa$ iterations convinces the verifier that the prover can answer each type of case except with probability $2^{-\kappa}$ each time. Hence, we treat each of the three cases as independent proofs and require $3 \kappa$ iterations overall.

### 5.1 Efficiency

While $3 \kappa$ is the trivial requirement to ensure the prover can indeed answer all three forms of $(a, b)$ with overwhelming probability, we believe $\kappa$-bit security can be achieved with a more efficient choice. However, more thorough analysis is needed. For example, using a biased challenge bit space where $c=0$ with 0.75 probability, we believe $2.4 \kappa$ iterations would provide soundness error less than $2^{-\kappa}$.

Because $3 \kappa$ (or perhaps $2.4 \kappa$ ) iterations of the sigma protocol are used rather than $\kappa$, this protocol will result in transcripts 3 (or 2.4) times larger than those from Figure 3. when proving the correctness of the points is important.

In terms of the protocol in Figure 3. verification only requires one extra check: in the case that $c=0$ (the else clause of the verification algorithm), after extracting ( $a, b$ ) from resp, the verifier simply keeps track of
how many of each case $(\star, \star),(\star, 0)$ and $(0, \star)$ are seen, and accepts overall only if the number of each case is roughly equal. The prover is able to check this requirement is met and repeat the proof generation if it is not, so exactly what "roughly equal" means can be made precise with a tradeoff between assurance and prover efficiency.
Alternatively, it could be enforced that the first $1 / 3$ of iterations must match $(\star, \star)$, the second $(\star, 0)$ and the third $(0, \star)$ - at the cost of the verifier knowing the parity of $a$ and $b$ even when $c=1$. Note that in many isogeny schemes/implementations, keys of the form $(1, \alpha)$ are already used exclusively (giving a slightly smaller keyspace, as discussed in the preliminaries on equivalent keys in Section 2.1), so we believe that leaking one further bit of parity of these ephemeral keys would not have a significant impact on the security of the scheme.

The size of our proofs can be further improved using a seed tree, as described in Section 2.4 . All commitment values $(a, b)$ could be generated from the leaves of such a seed tree, which would compress the size of responses (as all responses where challenge $c=0$ could be released in a compressed form). If we assume the biased challenge space where $c=0$ with 0.75 probability, this will allow three-quarters of the responses to be compressed. Concretely, for each leaf of the seed tree, a PRG with outputs that are $\left(2 e_{2} \log _{2} \ell_{2}\right)$-bits long can be used to obtain $(a, b)$ directly, and if both $a$ and $b$ are divisible by $\ell_{2}$, the leaf value can be incremented by one repeatedly until they are not both divisible by $\ell_{2}$. This should result in outputs roughly equal in the number of each case $(\star, 0),(0, \star)$, and $(\star, \star)$.

Remark 4. Note that if Conjecture 1 above does indeed hold, this protocol and proof may be adapted to no longer require the points $P_{3}, Q_{3}$ in the commitment. Such a proof would follow as long as the assurance that ker $\widehat{\psi^{\prime}}=\phi^{\prime}(\operatorname{ker} \widehat{\psi})$ still holds under the proof of the conjecture.

Assuming this conjecture holds, and assuming a similar conjecture holds for the Jao-Urbanik scheme, their method of SIDH key validation would be similar in size to ours (using the skewed challenge space and $2.4 \kappa$ iterations). While ours appears to require around 1.77 times as many commitment/challenge/response iterations as the Jao-Urbanik scheme, each iteration of our scheme is essentially halved in the size of the commitment (two rather than four curves) and challenge (one bit rather than two). The average response size is approximately the same at $\sim$ the size of one curve point, but using a seed tree to compress the responses as detailed above, our scheme would reduce in response size as well.

In terms of efficiency of verification, our scheme requires on average 1.25 isogeny computations per iteration, whereas theirs requires on average 2.2 isogeny computations per iteration. Taking the number of rounds into account, this makes the two schemes very similar in performance.

However, regardless of efficiency or proof size, their proof of soundness for this scheme assumes the invalid soundness proof discussed earlier in Section 3.2, while with the modification in Section 4 , ours is proven secure. Our scheme is also not limited to using the special base curves with extra automorphisms $\left(j\left(E_{0}\right)=0\right.$ or $\left.j\left(E_{1728}\right)=1728\right)$ so our scheme is more widely applicable.

We expect that further improvements to the efficiency and size of the scheme are possible with more analysis, but leave this for future work.

## 6 SIDH signatures and Non-Interactive Proof of Knowledge

We conclude with some brief, standard remarks about the use of the new protocol proposed above.
It is standard to construct a non-interactive signature scheme from an interactive protocol using the FiatShamir transformation (secure in the (quantum) random oracle model [Z19]). This works by making the challenge chall for the $t$ rounds of the ID scheme a random-oracle output from input the commitment com and a message $M$. That is, for message $M$,

$$
V_{1}^{\mathcal{O}}(\mathrm{com})=\mathcal{O}(\mathrm{com} \| M)
$$

Thus the prover does not need to interact with a verifier and can compute a non-interactive transcript. Because the sigma protocol described in the preceding sections not only proves knowledge of the secret isogeny between two curves, but also correctness of the torsion points in the public key, we obtain a signature scheme that is also a proof of knowledge of the secret key corresponding to a given SIDH public key, and proves that the SIDH public key is well-formed. For example, simply signing the public key with its own secret key using the new scheme gives a simple NIZK proof of well-formedness for the public key, which provides protection against adaptive attacks. The unforgeability of such a scheme is additionally based on the CSSI assumption.
