## ABSTRACT

In this work, we present an almost-surely terminating *asynchronous Byzantine agreement* (ABA) protocol for  $n$  parties. Our protocol requires  $O(n^2)$  expected time and is secure against a *computationally-unbounded* malicious (Byzantine) adversary, characterized by a *non-threshold* adversary structure  $\mathcal{Z}$ , which enumerates all possible subsets of potentially corrupt parties. Our protocol has *optimal resilience* where  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}$  condition; i.e. union of *no* three subsets from  $\mathcal{Z}$  covers all the  $n$  parties. To the best of our knowledge, this is the first almost-surely terminating ABA protocol with  $\mathbb{Q}^{(3)}$  condition. Previously, almost-surely terminating ABA protocol is known with *non-optimal* resilience where  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(4)}$  condition; i.e. union of *no* four subsets from  $\mathcal{Z}$  covers all the  $n$  parties. To design our protocol, we present a *shunning asynchronous verifiable secret-sharing* (SAVSS) scheme with  $\mathbb{Q}^{(3)}$  condition, which is of independent interest.

## 1 INTRODUCTION

*Byzantine agreement* (BA) [31], also known as fault-tolerant distributed consensus, is a fundamental problem in secure distributed computing. Informally, a BA protocol allows a set  $\mathcal{P}$  of  $n$  mutually distrusting parties with *private* input bits, to reach agreement on a common output bit, even if a subset of the parties are corrupted by a *computationally-unbounded* malicious (Byzantine) adversary, who can force the corrupt parties to behave arbitrarily during the protocol execution. BA protocols serve as a very important building block in secure *multiparty computation* (MPC) protocols [9, 36]. The BA problem has been widely studied over the last three decades and several fundamental results have been achieved, regarding the possibility and feasibility of BA protocols in various settings (see for instance [4, 30]). Recently, the BA problem has also received attention from several other research communities, after the advent of blockchain technologies (see for instance [24]).

The traditional way of characterizing the adversary is through a *threshold*, by assuming that adversary can corrupt any subset of up to  $t$  parties. In this setting, BA is achievable iff  $t < n/3$  [31]. Hirt and Maurer [26] and later Fitzi and Maurer [23] generalized the threshold model by introducing the *general-adversary* model (also known as the *non-threshold* setting in the literature). In the non-threshold setting, the adversary is characterized by an *adversary structure*  $\mathcal{Z} = \{Z_1, \dots, Z_h\} \subset 2^{\mathcal{P}}$ , which enumerates all possible subsets of potentially corrupt parties, such that adversary can select any subset from  $\mathcal{Z}$  for corruption during the execution of a protocol.

In the general-adversary model, BA is achievable iff  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition [23, 26].<sup>1</sup> There are several well-known motivations for modelling the distrust in the system through a non-threshold adversary (see for instance [19, 22, 25, 27]). For example, it allows for more flexibility, compared to the threshold model, especially when  $\mathcal{P}$  is not too large. To understand this, let  $\mathcal{P} = \{P_1, \dots, P_6\}$ . Then in the threshold setting, any BA protocol can tolerate at most 1 corrupt party. However, in the non-threshold setting, one can design a BA protocol tolerating an adversary characterized by the adversary structure  $\mathcal{Z} = \{\{P_1\}, \{P_2, P_4\}, \{P_3, P_5\}, \{P_3, P_6\}, \{P_2, P_5, P_6\}, \{P_4, P_5, P_6\}\}$ , where the adversary can corrupt up to 3 parties, by corrupting the subset  $\{P_2, P_5, P_6\}$  or  $\{P_4, P_5, P_6\}$ .

**Our Motivation and Results:** All the above results are in the *synchronous* communication model, where the parties are assumed to be synchronized through a *global* clock, implying strict upper bounds on the message delays. Consequently, protocol execution occurs as a sequence of communication *rounds*, where the parties are well aware of the beginning and end of each round. In a synchronous protocol, any expected message which does not get delivered within the known time bound can be attributed to a *corrupt* sender party. Unfortunately, guaranteeing such strict time-outs in extremely difficult in the real-world networks like the Internet, which are better modelled through *asynchronous* communication model [13]. In the asynchronous model, *no* timing assumptions are made and the messages can be arbitrarily, but finitely delayed. The only guarantee is that every sent message is eventually delivered, but the messages need not be delivered in the same order in which they were sent. To model the worst case scenario, adversary is given the full control of the message scheduling in an asynchronous network. Consequently, no party can distinguish between a *corrupt* sender party (who does not send any message) and a *slow honest* sender party (whose messages are arbitrarily delayed). As an implication of this, in any asynchronous protocol, no party can afford to wait to receive messages from all the parties, to avoid an

<sup>1</sup>Given a set of parties  $\mathcal{P}' \subseteq \mathcal{P}$ , we say that  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(k)}(\mathcal{P}', \mathcal{Z})$  condition, if the union of any  $k$  subsets from  $\mathcal{Z}$  does not cover the entire set  $\mathcal{P}'$ .

endless wait and hence at every step of the protocol, a party may afford to receive messages from only a subset of parties, ignoring communication from potentially slow *honest* parties. As a result of this, asynchronous protocols are more challenging to design than their synchronous counterparts.

Unlike synchronous protocols, asynchronous protocols are executed as a sequence of events, based on the order in which messages are delivered. Following the results in the synchronous setting, *asynchronous BA* (ABA) is possible iff  $t < n/3$  in the threshold setting, while ABA in the non-threshold setting is possible only if  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition. Compared to the synchronous BA protocols, there are several inherent limitations of ABA protocols. The seminal FLP impossibility result [21] states that *any* (deterministic) ABA protocol *must have* non-terminating runs, where the honest parties (who are not under the control of the adversary) keep on running the protocol forever to obtain an output. A powerful paradigm to circumvent this impossibility result is to embrace randomness, pioneered by Rabin [35] and Ben-Or [7]. There are two categories of randomized ABA protocols. The first category is that of  $(1 - \epsilon)$ -terminating ABA protocols [14, 33], where the honest parties *may not* terminate the protocol with probability  $\epsilon$ , where  $\epsilon > 0$  is some error parameter. The second category is that of *almost-surely terminating* ABA protocols [1, 5], where the honest parties terminate the protocol, asymptotically with probability 1. While the first category of ABA protocols are used in *statistically-secure* asynchronous MPC (AMPC) protocols [10, 16] where a negligible error is allowed in the security properties, the latter category of protocols are used in *perfectly-secure* AMPC protocols [6, 8, 18, 34] where all security properties are achieved *without* any error.

In this work, we focus on almost-surely terminating ABA protocols. The works of [1, 5] present efficient almost-surely terminating ABA protocols in the *threshold* setting with the *optimal* resilience of  $t < n/3$ . However, to the best of our knowledge, we are *not* aware of any almost-surely terminating ABA protocol in the *non-threshold* setting with *optimal resilience*. Motivated by this, we ask the following central question:

*Does there exist an almost-surely terminating ABA protocol where the adversary structure  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition?*

We answer the above question affirmatively by presenting an almost-surely terminating ABA protocol with the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition. Our protocol is efficient and requires  $O(n^2)$  expected running time, where the expected computation and communication performed by the parties is polynomial in  $n$ .

**Related Work:** Not much work has been done in the domain of ABA against non-threshold adversaries. In [17], the authors presented an *almost-surely terminating* ABA protocol. Compared to our protocol, the expected running time of their protocol is a *constant*. However, their protocol has *non-optimal* resilience, where the underlying adversary structure  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(4)}(\mathcal{P}, \mathcal{Z})$  condition. In a technical report [29], the authors refer to an ABA protocol in [28] with  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition, to show that the condition  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  is sufficient for designing ABA protocol. However, the work of [28] is *not* available in the public domain and the exact details of the ABA protocol is *not* known. Also, it is not clear whether the protocol in [28] is  $(1 - \epsilon)$  or almost-surely terminating. Given the importance

of ABA and the general-adversary model, our work fills the gap in the literature by presenting an almost-surely terminating ABA protocol with complete formal details and formal security proofs.

**Technical Overview:** To design our ABA protocol, we generalize the framework of [1, 5, 37] in the *threshold* setting (which is further based on [7, 20, 35]), to the general-adversary model. The framework reduces ABA to the design of an asynchronous *common-coin* (CC) protocol, which allows the honest parties to output a common random bit, with certain non-zero *success probability*. The design of CC protocol is further reduced to another well-known primitive called *asynchronous verifiable secret sharing* (AVSS) [8, 15]. Informally, an AVSS scheme consists of a sharing-phase protocol and a reconstruction-phase protocol. During the sharing-phase, there exists a designated *dealer* with some *private* input (called secret), which it shares among the parties, without revealing anything about the secret to the adversary. The “verifiability” of the scheme guarantees that even if dealer is *corrupt*, it has “consistently” shared some value among the parties. During the reconstruction-phase protocol, the parties robustly reconstruct the value shared during the sharing-phase, even if the corrupt parties (including a potentially corrupt dealer) behaves maliciously.

It is well-known that *perfectly-secure* (error-free) AVSS in the *threshold* setting necessarily requires  $t < n/4$  [2, 8]. Hence to design a CC protocol with  $t < n/3$ , the work of [1] introduces a *weaker* variant of AVSS called *shunning* AVSS (SAVSS). Intuitively, depending upon the behaviour of the adversary, an SAVSS scheme either guarantees all the security properties of an AVSS or ensures that some *honest* party is able to *locally* detect and shun at least one *corrupt* party (also called as *local-conflict*) for all future communication. Once all corrupt parties are shunned by all honest parties, then there will be no further errors and hence SAVSS will provide all the security guarantees of AVSS. Based on their SAVSS, [1] designed a shunning-variant of CC called *shunning common-coin* (SCC) protocol, where either all honest parties output a common random bit with certain success probability or some local-conflict occurs.

To generalize the framework of [1], we present a perfectly-secure SAVSS scheme with  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition. The scheme guarantees that if the properties of AVSS are not achieved, then at least one *new* local-conflict occurs. Consequently, it may take  $O(n^2)$  “failed” SAVSS instances before all corrupt parties are shunned by all honest parties. By deploying our SAVSS we then design an SCC protocol against general adversaries with  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition, where the success probability is  $\frac{1}{n}$ . Finally, this SCC protocol when used in the (generalized) framework of [7, 35] leads to our ABA protocol with  $O(n^2)$  expected running time.

**Open Problems:** In the *threshold* setting, almost-surely terminating ABA protocol with *optimal resilience* (i.e.  $t < n/3$ ) and *best* running time is due to [5], where the expected running time is  $O(n)$ . We do not know how to generalize the protocol of [5] and get an almost-surely terminating ABA protocol with  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition and  $O(n)$  expected running time. Designing an almost-surely terminating ABA protocol with a *constant* expected running time and with *optimal resilience* even against threshold adversaries has been a long-standing open problem.

## 2 PRELIMINARIES

We assume the *secure-channel* model, where the parties in  $\mathcal{P} = \{P_1, \dots, P_n\}$  are connected by pair-wise private and authentic channels. The distrust is modelled by a centralized *malicious* (Byzantine) adversary  $\text{Adv}$ , characterized by an adversary structure  $\mathcal{Z} = \{Z_1, \dots, Z_h\} \subset 2^{\mathcal{P}}$ . The adversary is *static*, who decides the set of corrupt parties  $Z^* \in \mathcal{Z}$ , at the beginning of the execution of any protocol. Parties not under the control of  $\text{Adv}$  are called *honest*. Given  $\mathcal{P}' \subseteq \mathcal{P}$ , we say that  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(k)}(\mathcal{P}', \mathcal{Z})$  condition, if for every  $Z_{i_1}, \dots, Z_{i_k} \in \mathcal{Z}$ , the condition  $\mathcal{P}' \not\subseteq Z_{i_1} \cup \dots \cup Z_{i_k}$  holds [27]. We follow the asynchronous communication model of [13], where the channels among the parties are asynchronous and where the messages are arbitrarily yet finitely delayed, with the guarantee that every sent message is eventually delivered.

In our protocols, each  $P_i$  maintains a local *block-set*  $\mathcal{B}_i$  across all protocol instances and a *wait-set*  $\mathcal{W}_i$ , which are initialized to  $\emptyset$ . Note that  $P_i$  maintains a *single*  $\mathcal{B}_i$  set, where as a *separate*  $\mathcal{W}_i$  set is maintained for each SAVSS instance. Party  $P_i$  includes  $P_j$  in  $\mathcal{B}_i$  if during some protocol instance,  $x$  is expected from  $P_j$ , but instead  $x' \neq x$  is received. Party  $P_i$  is said to be in *local-conflict* with  $P_j$  when  $P_j \in \mathcal{B}_i$ . Party  $P_i$  includes  $P_j$  in  $\mathcal{W}_i$  corresponding to some SAVSS instance, if during that instance,  $P_i$  is expecting some message from  $P_j$ . While a party making an entry in  $\mathcal{B}_i$  remains part of it until the end of the execution of the ABA protocol, any entry in a wait set is *temporary* and removed as and when the expected communication happens. Until the receipt of the desired communication from a party in  $\mathcal{W}_i$ , party  $P_i$  suspends (saves yet does not use) its future communication. Looking ahead, the way  $\mathcal{W}_i$  and  $\mathcal{B}_i$  sets are created and maintained, it will be guaranteed that *no honest party* is ever included in the  $\mathcal{B}_i$  set of any *honest*  $P_i$ . Moreover, if any *honest*  $P_j$  is ever included in the  $\mathcal{W}_i$  set of any *honest*  $P_i$ , then  $P_i$  eventually removes  $P_j$  from  $\mathcal{P}_i$ .

In our SAVSS scheme, the parties perform computations over an algebraic structure  $(\mathbb{K}, +, \cdot)$ , which is either a finite ring or a field with  $|\mathbb{K}| \geq n$ . Looking ahead, this is required to achieve the desired success probability in our SCC protocol.

### 2.1 Definitions

We now present the various definitions, as used in the paper.

**Definition 2.1 (Shunning Asynchronous Verifiable Secret Sharing (SAVSS)).** Let  $(\Pi_{\text{Sh}}, \Pi_{\text{Rec}})$  be a pair of protocols for the parties in  $\mathcal{P}$ , where each  $P_i$  maintains a local  $\mathcal{B}_i$  and  $\mathcal{W}_i$  set, and for a special party *dealer*  $P_D \in \mathcal{P}$  that has a private input  $s \in \mathbb{K}$  for  $\Pi_{\text{Sh}}$ . Then  $(\Pi_{\text{Sh}}, \Pi_{\text{Rec}})$  is an SAVSS scheme if the following requirements hold for every possible  $\text{Adv}$ .

- **Output Computation:** (a) If  $P_D$  is *honest* and all honest parties participate in  $\Pi_{\text{Sh}}$ , then each honest party eventually obtains an output in  $\Pi_{\text{Sh}}$ . (b) If some honest party obtains an output in  $\Pi_{\text{Sh}}$ , then every other honest party eventually obtains an output in  $\Pi_{\text{Sh}}$ . (c) If all honest parties participate in  $\Pi_{\text{Rec}}$ , then every honest party eventually obtains an output in  $\Pi_{\text{Rec}}$ .
- **Correctness:** If the honest parties compute an output during  $\Pi_{\text{Sh}}$ , then there exists some  $\bar{s} \in \mathbb{K}$ , where  $\bar{s} = s$  for an *honest*  $P_D$ , such that *one* of the following holds:
  - All honest parties output  $\bar{s}$  during  $\Pi_{\text{Rec}}$ ; or

- Some corrupt parties are included in the  $\mathcal{B}$  sets of some honest parties.
- **Privacy:** If  $P_D$  is *honest*, then the view of  $\text{Adv}$  during  $\Pi_{\text{Sh}}$  is independent of  $s$ .

**Definition 2.2 (Shunning Common Coin (SCC)).** Let  $\Pi_{\text{SCC}}$  be a protocol for the parties in  $\mathcal{P}$ , with each  $P_i$  maintaining a local  $\mathcal{B}_i$  and  $\mathcal{W}_i$  set and where each party has some local random input and a binary output. Then  $\Pi_{\text{SCC}}$  is a  $p$ -SCC protocol for a given  $p$  where  $0 < p < 1$ , if all the following hold for every possible  $\text{Adv}$ .

- **Completion:** If all honest parties participate in  $\Pi_{\text{SCC}}$ , then every honest party eventually obtains an output.
- **Correctness:** One of the following holds.
  - For every  $\sigma \in \{0, 1\}$ , all honest parties output  $\sigma$  with probability at least  $p$ ; or
  - Some corrupt parties are included in the  $\mathcal{B}$  sets of some honest parties.

**Remark 2.3 (On the Termination Guarantees of Our Sub-Protocols).** For simplicity and for the ease of analysis, we *do not* put any *termination* criteria for the various sub-protocols (including SAVSS and SCC) used in our ABA protocol and the parties may keep on running these sub-protocol instances, even after obtaining an output. Looking ahead, the termination criteria of our ABA protocol will ensure that the parties terminate all sub-protocol instances upon obtaining their respective outputs in the ABA protocol.

**Definition 2.4 (Almost-Surely Terminating Asynchronous Byzantine Agreement (ABA)).** Let  $\Pi_{\text{ABA}}$  be a protocol for the parties in  $\mathcal{P}$ , where each  $P_i$  has a private input bit  $b_i$  and a possible output bit. Then,  $\Pi_{\text{ABA}}$  is an almost-surely terminating ABA protocol, if the following requirements hold for every possible  $\text{Adv}$ .

- **Termination:** If all honest parties participate in  $\Pi_{\text{ABA}}$ , then asymptotically with probability one, each honest  $P_i$  eventually terminates the protocol. That is,

$$\lim_{T \rightarrow \infty} \Pr[\text{An honest } P_i \text{ obtains its output by local time } T] = 1,$$

where the probability is over the random coins of the honest parties and the adversary in the protocol.

- **Agreement:** All honest parties output a common bit.
- **Validity:** If all honest parties have the same input bit  $\sigma$ , then all honest parties eventually output  $\sigma$ .

### 2.2 Existing Asynchronous Primitives

We use the following existing asynchronous primitives.

**Asynchronous Reliable Broadcast (Acast):** An Acast protocol allows a designated *sender*  $P_S \in \mathcal{P}$  to identically send a message  $m \in \{0, 1\}^\ell$  to all the parties. If  $P_S$  is *honest*, then all honest parties eventually output  $m$ . On the other hand, if  $P_S$  is *corrupt* and some honest party outputs an  $m^* \in \{0, 1\}^\ell$  (where  $m^*$  may be *different* from  $m$ ), then every other honest party eventually outputs  $m^*$ . In [29], a perfectly-secure Acast protocol is presented with a communication complexity of  $\mathcal{O}(n^2\ell)$  bits, provided the underlying adversary structure  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition. The protocol is obtained by generalizing the Bracha's Acast protocol against threshold adversaries with  $t < n/3$  [12]. We will use the following terminologies while invoking the Acast protocol: we will say that " $P_i$  broadcasts  $m$ " to mean that  $P_i$  acts as a sender and

invokes an instance of the Acast protocol with input  $m$  and the parties participate in this instance. Similarly, we will say that “ $P_j$  receives  $m$  from the broadcast of  $P_i$ ” to mean that party  $P_j$  outputs  $m$  in the corresponding instance of Acast.

**Asynchronous Vote Protocol:** In a voting protocol (also known as *gradecast*), every party has a single bit as input and each party’s output can have *five* different forms:

- For  $\sigma \in \{0, 1\}$ , the output  $(\sigma, 2)$  stands for “overwhelming majority for  $\sigma$ ”;
- For  $\sigma \in \{0, 1\}$ , the output  $(\sigma, 1)$  stands for “distinct majority for  $\sigma$ ”;
- The output  $(\Lambda, 0)$  stands for “non-distinct majority”.

A voting protocol ensures the following properties:

- If each honest party has the same input  $\sigma$ , then every honest party outputs  $(\sigma, 2)$ .
- If some honest party outputs  $(\sigma, 2)$ , then every other honest party outputs either  $(\sigma, 2)$  or  $(\sigma, 1)$ .
- If some honest party outputs  $(\sigma, 1)$  and no honest party outputs  $(\sigma, 2)$ , then each honest party outputs either  $(\sigma, 1)$  or  $(\Lambda, 0)$ .

In [14], a voting protocol satisfying the above requirements is presented against threshold adversaries, provided  $t < n/3$  holds. The protocol is generalized against non-threshold adversaries in [17], provided the underlying  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition. The protocol called  $\Pi_{\text{Vote}}$  incurs a communication of  $O(n^5)$  bits.

### 3 SAVSS WITH $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$ CONDITION

In this section, we present our SAVSS scheme (see Fig 1). The scheme is obtained by modifying the perfectly-secure AVSS scheme of [17] (which is further based on [32]) and considers a *sharing specification*  $\mathbb{S} = \{S_1, \dots, S_h\}$ , where for  $q = 1, \dots, h$  the set  $S_q = \mathcal{P} \setminus Z_q$  and where  $\mathcal{Z} = \{Z_1, \dots, Z_h\}$  is the underlying adversary structure. During the sharing-phase protocol  $\Pi_{\text{Sh}}$ , the dealer randomly picks a vector of shares  $[s] = (s_1, \dots, s_h)$  for its secret  $s$ , such that  $s = s_1 + \dots + s_h$  and distributes the share  $s_q$ , denoted by  $[s]_q$ , to all the parties in the set  $S_q$ . If the dealer is *honest*, then this does not reveal any information about  $s$  to the adversary, as adversary will be missing at least one share and so the probability distribution of the shares learnt the adversary will be independent of  $s$ . To verify whether a potentially *corrupt* dealer has distributed a common share  $[s]_q$  to all the honest parties in the set  $S_q$ , the parties in  $S_q$  exchange the supposedly common share and publicly acknowledge if they received the same share. Based on these public acknowledgements, the parties check whether for each set  $S_q \in \mathbb{S}$ , there exists a subset of parties  $S'_q$  who have acknowledged the receipt of a common share from the dealer, such that  $S'_q$  is guaranteed to have at least one *honest* party. Notice that such a subset  $S'_q$  is bound to exist for an *honest* dealer, since for an *honest* dealer, all the *honest* parties in  $S_q$  will receive the same share from the dealer and the set of honest parties in each set  $S_q$  is *non-empty*, which follows from the fact that  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition. To ensure that all honest parties have an agreement on the subsets  $S'_q$ , the dealer is assigned the task of identifying the subsets  $S'_q$  and publicly declaring them.

To find the subsets  $S'_q$ , the dealer actually finds a *single* “core” subset of parties  $C$  where  $\mathcal{P} \setminus C \in \mathcal{Z}$ , such that corresponding to every  $S_q \in \mathbb{S}$ , there exists a subset  $S'_q \subseteq (S_q \cap C)$ , where  $S_q \setminus S'_q \in \mathcal{Z}$

and where *all* the parties in  $S'_q$  have publicly acknowledged the receipt of a common share from the dealer. An *honest* dealer will eventually find such a core set  $C$ , as the set of *honest* parties in the system constitute a candidate  $C$  for an *honest* dealer. Upon finding a set  $C$  satisfying the above conditions, dealer publicly announces it and the parties “accept” the set  $C$  after verifying whether indeed the announced  $C$  satisfies the above properties.

During the reconstruction-phase protocol  $\Pi_{\text{Rec}}$ , the goal is to get the share  $[s]_q$  corresponding to every set  $S_q \in \mathbb{S}$ , upon which the shared secret can be reconstructed by computing  $[s]_1 + \dots + [s]_h$ . To get the share  $[s]_q$  corresponding to  $S_q$ , *all* the parties in the set  $(S_q \cap C)$  are asked to make the share received from the dealer public. However, due to the asynchronous communication, to avoid an indefinite wait, the parties *cannot* afford for *all* the parties in  $(S_q \cap C)$  to make their version of the share  $[s]_q$  public, as the potentially *corrupt* parties in  $(S_q \cap C)$  may never make any share public. Consequently, as soon as *any* party from  $(S_q \cap C)$  makes public its version of  $[s]_q$ , it is considered towards the reconstruction of  $s$ . However, this may lead to reconstruction of an *incorrect*  $s$ , as a potentially *corrupt* party from  $(S_q \cap C)$  may make public an *incorrect* version of  $[s]_q$ . But this will lead to the honest party(ies) in  $S'_q$  getting into local-conflict with this corrupt party.

Each instance of SAVSS is associated with a unique id  $\text{sid} \in \mathbb{N}$ . All messages communicated during the SAVSS instance  $\text{sid}$  are tagged with this id. However, for simplicity, we skip tagging every message explicitly with  $\text{sid}$  in the formal description of the scheme. During the protocol  $\Pi_{\text{Sh}}$ , once the core set  $C$  is agreed upon, the parties *locally* populate their respective  $\mathcal{W}$  sets, anticipating the values they expect from the various parties during the protocol  $\Pi_{\text{Rec}}$ . At the beginning of each instance of the SAVSS, a corresponding *memory management* protocol  $\Pi_{\text{MM}}$  is also invoked, based on which each party *locally* decides whether to process a received message as per the SAVSS, delay it temporarily or block it permanently. Protocol  $\Pi_{\text{MM}}$  examines the messages produced by the various parties during the reconstruction phase and accordingly the  $\mathcal{W}$  and  $\mathcal{B}$  sets of the parties are updated. We stress that the parties keep executing the  $\Pi_{\text{MM}}$  protocol with id  $\text{sid}$ , even after obtaining their respective outputs in the  $\Pi_{\text{Sh}}$  and  $\Pi_{\text{Rec}}$  protocols with id  $\text{sid}$ . This ensures that if some message is pending from a party for instance  $\text{sid}$ , then its communication is ignored by the  $\Pi_{\text{MM}}$  protocol in any future instance  $\text{sid}' > \text{sid}$ .

#### Scheme SAVSS

Protocol  $\Pi_{\text{Sh}}(\mathcal{P}, \mathcal{Z}, \mathbb{S}, P_D, s)$

- **Distribution of Shares** – On having the input  $s \in \mathbb{K}$ , the dealer  $P_D$  executes the following steps.
  - Randomly select the shares  $s_1, \dots, s_h$ , subject to the condition that  $s_1 + \dots + s_h = s$  holds.
  - For  $q = 1, \dots, h$ , set  $[s]_q = s_q$  and send  $[s]_q$  to all the parties in the set  $S_q$ .
- **Pair-wise Consistency Check** – Each party  $P_i \in \mathcal{P}$  (including  $P_D$ ), executes the following steps.
  - Wait to receive a share  $s_{qi}$  from  $P_D$ , corresponding to every  $S_q \in \mathbb{S}$  such that  $P_i \in S_q$ . Upon receiving, send the share  $s_{qi}$  to every party  $P_j \in S_q$ .
  - Broadcast an  $\text{OK}(i, j)$  message, if all the following hold.

1.  $P_i$  has received a share  $s_{qj}$  from  $P_j$ , corresponding to every  $S_q \in \mathbb{S}$  such that  $P_i, P_j \in S_q$ ;
  2. The condition  $s_{qi} = s_{qj}$  holds.
- **Constructing CORE Set and Public Announcement** –  $P_D$  executes the following steps.
    - Check if there exists a subset of parties  $C \subseteq \mathcal{P}$ , such that all the following hold. Upon finding such a  $C$ , broadcast it.
      1.  $\mathcal{P} \setminus C \in \mathcal{Z}$ ;
      2. Corresponding to every  $P_i, P_j \in C$ , the messages  $\text{OK}(i, j)$  and  $\text{OK}(j, i)$  have been received from the broadcast of  $P_i$  and  $P_j$  respectively.
      3. Corresponding to every  $S_q \in \mathbb{S}$ , there exists a subset  $S'_q \subseteq (S_q \cap C)$ , such that  $S_q \setminus S'_q \in \mathcal{Z}$ .
  - **Verifying CORE Set and Populating Waiting Sets** – Each  $P_i \in \mathcal{P}$  (including  $P_D$ ) executes the following steps.
    - Wait to receive a set  $C$  from the broadcast of  $P_D$  and then *accept* and output  $C$ , if all the following hold.
      1.  $\mathcal{P} \setminus C \in \mathcal{Z}$ ;
      2. Corresponding to every  $P_i, P_j \in C$ , the messages  $\text{OK}(i, j)$  and  $\text{OK}(j, i)$  have been received from the broadcast of  $P_i$  and  $P_j$  respectively.
      3. Corresponding to every  $S_q \in \mathbb{S}$ , there exists a subset  $S'_q \subseteq (S_q \cap C)$ , such that  $S_q \setminus S'_q \in \mathcal{Z}$ .
    - If a set  $C$  is accepted, then populate the set  $\mathcal{W}_{(i, \text{sid})}$  as follows.
      - If  $P_i = P_D$ , then for each  $P_j \in C$  and each  $S_q \in \mathbb{S}$  where  $P_j \in S_q$ , add the tuple  $(q, P_j, [s]_q)$  to  $\mathcal{W}_{(i, \text{sid})}$ . This is interpreted as  $P_D$  expects  $P_j$  to reveal the share  $[s]_q$  on the behalf of the set  $S_q$  during the reconstruction protocol.
      - If  $P_i \in C$ , then corresponding to each  $S_q \in \mathbb{S}$  where  $P_i \in S_q$  and each  $P_j \in S_q \cap C$ , add the tuple  $(q, P_j, s_{qi})$  to  $\mathcal{W}_{(i, \text{sid})}$ . This is interpreted as  $P_i$  expects  $P_j$  to reveal the share  $s_{qi}$  on the behalf of the set  $S_q$  during the reconstruction protocol.
      - Else corresponding to every  $P_j \in C$  and every  $S_q \in \mathbb{S}$  where  $P_j \in S_q$ , add the tuple  $(q, P_j, \star)$  to  $\mathcal{W}_{(i, \text{sid})}$ . This is interpreted as  $P_i$  expects  $P_j$  to reveal some share on the behalf of the set  $S_q$  during the reconstruction protocol.

Protocol  $\Pi_{\text{Rec}}(\mathcal{P}, \mathcal{Z}, \mathbb{S}, P_D, s)$

- **Making the Shares Public** – For  $q = 1, \dots, h$ , each party  $P_i \in C \cap S_q$  broadcasts the shares  $\{s_{qi}\}_{P_i \in S_q \cap C}$ .
- **Reconstructing the Secret** – Each  $P_j \in \mathcal{P}$  outputs  $s^* = [s]_1^* + \dots + [s]_h^*$ , where for  $q = 1, \dots, h$ , party  $P_j$  computes  $[s]_q^*$  as follows.
  - If  $P_j \in (C \cap S_q)$ , then set  $[s]_q^* = s_{qj}$ .
  - If  $P_j \notin (C \cap S_q)$ , then set  $[s]_q^* = s_{qi}$ , if  $s_{qi}$  is received from the broadcast of some  $P_i \in C \cap S_q$ .

Protocol  $\Pi_{\text{MM}}(\mathcal{P}, \mathcal{Z}, \mathbb{S}, P_D, s)$

The following code is executed by  $P_i \in \mathcal{P}$ , if a set  $C$  is accepted:

- **Initialization:** Initialize  $\mathcal{W}_{(i, \text{sid})}$  and  $\mathcal{B}_i$  to  $\emptyset$ . The set  $\mathcal{B}_i$  is a set that is initialized by the party  $P_i$  only once (when  $\text{sid} = 0$ ) and dynamically updated during the various instances of  $\Pi_{\text{MM}}$ . The set  $\mathcal{W}_{(i, \text{sid})}$  is initialized in and maintained for SAVSS instance with id  $\text{sid}$  only.
- **Suspending Messages:** If any message is received from  $P_j$  during SAVSS with id  $\text{sid}$ , then block the message as per the following conditions.
  - If  $P_j \in \mathcal{B}_i$ , then discard the message.

- If there exists a tuple of the form  $(\star, P_j, \star)$  in the  $\mathcal{W}_{(i, \text{sid}' )}$  set for any  $\text{sid}' < \text{sid}$ , then do not forward the message to SAVSS with id  $\text{sid}$ .
- **Filtering Parties from Waiting Lists:** Corresponding to every  $P_j \in \mathcal{P}$ , if  $P_j \notin \mathcal{B}_i$  and if a share  $s_{qj}$  is received from the broadcast of  $P_j$  on the behalf of the set  $S_q$  during  $\Pi_{\text{Rec}}$  with id  $\text{sid}$ , then do the following, provided  $P_j \in S_q \cap C$  and there exists a tuple of the form  $(q, P_j, \text{val}) \in \mathcal{W}_{(i, \text{sid})}$ .
  - If  $\text{val} = \star$ , then remove  $(q, P_j, \text{val})$  from  $\mathcal{W}_{(i, \text{sid})}$ .
  - If  $\text{val} \neq \star$  and  $\text{val} = s_{qj}$ , then remove  $(q, P_j, \text{val})$  from  $\mathcal{W}_{(i, \text{sid})}$ .
  - If  $\text{val} \neq \star$  and  $\text{val} \neq s_{qj}$ , then add  $P_j$  to  $\mathcal{B}_i$ .

<sup>a</sup>If there are multiple such parties  $P_i$  from whose broadcast  $P_j$  receives some  $s_{qi}$ , then consider the first party  $P_i$  among them.

**Figure 1: The SAVSS scheme with protocols for sharing, reconstruction and memory management with session id  $\text{sid}$**

We next prove the properties of our SAVSS.

**LEMMA 3.1 (Properties of SAVSS Memory Management Protocol).** *The following hold for every honest  $P_i \in \mathcal{P}$  during the protocol  $\Pi_{\text{MM}}$  with id  $\text{sid}$  for any  $\text{sid} \in \mathbb{N}$ , irrespective of  $P_D$ .*

- If  $P_j$  is included in  $\mathcal{B}_i$  then  $P_j$  is corrupt.
- If  $P_j$  is honest, then any triplet of the form  $(\star, P_j, \star)$  present in  $\mathcal{W}_{(i, \text{sid})}$  is eventually removed.

**PROOF.** If  $P_j$  is *honest*, then it eventually broadcasts all the messages it is supposed to broadcast during the protocol  $\Pi_{\text{Rec}}$  with id  $\text{sid}$ , which are eventually received by every honest  $P_i$ . Hence every triplet of the form  $(\star, P_j, \star)$  will be eventually removed from  $\mathcal{W}_{(i, \text{sid})}$ . Moreover, an *honest*  $P_j$  broadcasts the shares as received from  $P_D$  during the protocol  $\Pi_{\text{Sh}}$  with id  $\text{sid}$ . So the conditions for including  $P_j$  to  $\mathcal{B}_i$  are never satisfied.  $\square$

**LEMMA 3.2.** *For any  $\text{sid} \in \mathbb{N}$ , the following hold during the  $(\Pi_{\text{Sh}}, \Pi_{\text{Rec}})$  protocols with id  $\text{sid}$ : (a) If  $P_D$  is honest and all honest parties participate in  $\Pi_{\text{Sh}}$ , then each honest party eventually outputs  $C$ . (b) If some honest party outputs  $C$  in  $\Pi_{\text{Sh}}$ , then every other honest party eventually outputs  $C$  in  $\Pi_{\text{Sh}}$ . (c) If all honest parties participate in  $\Pi_{\text{Rec}}$ , then every honest party eventually obtains an output in  $\Pi_{\text{Rec}}$ .*

**PROOF.** We note that during  $\Pi_{\text{Sh}}$  and  $\Pi_{\text{Rec}}$ , the messages of every honest party is cleared by the  $\Pi_{\text{MM}}$  protocol and eventually delivered to the honest recipients, which follows from Lemma 3.1. We first consider an *honest*  $P_D$ . In this case, corresponding to every  $S_q \in \mathbb{S}$ , every *honest* party  $P_i \in S_q$  receives the share  $s_{qi}$  from  $P_D$ , which will be the *same* as  $[s]_q$ . Consequently, every honest  $P_i$  eventually broadcasts an  $\text{OK}(i, j)$  message, corresponding to every *honest*  $P_j$ . Let  $Z_c \in \mathcal{Z}$  be the set of *corrupt* parties and let  $\mathcal{H} = \mathcal{P} \setminus Z_c$  be the set of *honest* parties. Next consider an arbitrary  $S_q \in \mathbb{S}$ . It is easy to see that  $S_q \setminus (S_q \cap \mathcal{H}) \subseteq Z_c \in \mathcal{Z}$ . It then follows that  $P_D$  eventually finds a candidate  $C$  set and broadcasts the same, since we have shown that the set  $\mathcal{H}$  satisfies all the properties of a candidate  $C$  set. Consequently, every honest party will eventually receive a  $C$  set from the broadcast of  $P_D$ , accepts it and outputs  $C$ . This proves the first part of the lemma.

For the second part of the lemma, let  $P_h$  be the *first* honest party who outputs  $C$  during  $\Pi_{\text{Sh}}$ . This implies that  $P_h$  receives the set  $C$  from the broadcast of  $P_D$  and accepts it. It then follows that every other honest party also eventually receives  $C$  from the broadcast

of  $P_D$  and the conditions for accepting  $C$  will eventually hold for those honest parties as well. Consequently, every other honest party eventually outputs  $C$  during  $\Pi_{Sh}$ .

For the third part, we first note that honest parties participate in  $\Pi_{Rec}$ , only after accepting  $C$ . We also note that corresponding to every  $S_q \in \mathbb{S}$ , there exists at least one *honest* party in the set  $S_q \cap C$ , that is  $S_q \cap C \cap \mathcal{H} \neq \emptyset$ . This is because as per the protocol conditions,  $\mathcal{P} \setminus C \in \mathcal{Z}$ ,  $S_q = \mathcal{P} \setminus Z_q$  and  $\mathcal{H} = \mathcal{P} \setminus Z_c$ , so if  $S_q \cap C \cap \mathcal{H} = \emptyset$ , then it implies that  $\mathcal{Z}$  does not satisfy the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition, which is a contradiction. Let  $P_j$  be an *honest* party in the set  $S_q \cap C$ . During  $\Pi_{Rec}$ , party  $P_j$  will broadcast the share  $s_{qj}$  received from  $P_D$  on the behalf of the set  $S_q$ , which is eventually delivered to every honest party. Consequently, every *honest* party  $P_i$  will eventually set the share  $[s]_q^*$  to some value and reconstructs some value  $s^*$ .  $\square$

LEMMA 3.3. *For any  $sid \in \mathbb{N}$ , the following holds during the  $(\Pi_{Sh}, \Pi_{Rec}, \Pi_{MM})$  protocols with id sid: If the honest parties output  $C$  during  $\Pi_{Sh}$ , then there exists a unique value  $\bar{s}$ , where  $\bar{s} = s$  for an honest  $P_D$ , such that one of the following holds.*

- All honest parties output  $s^* = \bar{s}$  during  $\Pi_{Rec}$ ; or
- At least one new local-conflict occurs during  $\Pi_{MM}$  between an honest and a corrupt party.

PROOF. Let the honest parties output a set  $C$  during  $\Pi_{Sh}$ . This implies that the honest parties have accepted  $C$ , broadcasted by  $P_D$ . Now consider an arbitrary  $S_q \in \mathbb{S}$ . As shown in the proof of Lemma 3.2, there exists at least one *honest* party in the set  $S_q \cap C$ . We first note that all *honest* parties in the set  $S_q \cap C$  receive the same share, say  $s_q$ , from  $P_D$ . This is because every honest party  $P_k \in S_q \cap C$  has broadcasted an  $OK(k, l)$  message, corresponding to every honest  $P_l \in S_q \cap C$ , implying that the condition  $s_{qk} = s_{ql}$  holds, where  $s_{qk}$  and  $s_{ql}$  are the shares corresponding to  $S_q$ , received by  $P_k$  and  $P_l$  respectively. We define

$$\bar{s} \stackrel{def}{=} \sum_{q=1, \dots, h} s_q.$$

It is easy to see that if  $P_D$  is *honest*, then  $\bar{s} = s$  holds.

Next consider an arbitrary *honest* party  $P_j$ . From Lemma 3.2, party  $P_j$  eventually reconstructs some value  $s^*$  during  $\Pi_{Rec}$ . Let  $s^* \neq \bar{s}$ . This implies that there exists at least one  $S_q \in \mathbb{S}$ , such that during  $\Pi_{Rec}$ , party  $P_j$  has set  $[s]_q^*$  to  $s_{qi}$  where  $s_{qi}$  is received from the broadcast of some  $P_i \in S_q \cap C$  and  $s_{qi} \neq s_q$ . Note that  $P_i$  is *corrupt*, as every *honest* party in  $S_q \cap C$  broadcasts the share  $s_q$  during  $\Pi_{Rec}$ . We also note that the share  $s_{qi}$  broadcasted by  $P_i$  is eventually received by all *honest* parties in  $S_q \cap C$ . Now consider an arbitrary *honest* party  $P_k \in S_q \cap C$ . From the protocol steps, during  $\Pi_{Sh}$ , party  $P_k$  broadcasts the message  $OK(k, i)$  corresponding to  $P_i$  and adds the tuple  $(q, P_i, s_q)$  to  $\mathcal{W}_{(k, sid)}$ . Since during  $\Pi_{Rec}$  party  $P_i$  broadcasts  $s_{qi} \neq s_q$ , it follows that during the protocol  $\Pi_{MM}$ , the local-conflict  $(P_k, P_i)$  occurs and party  $P_k$  adds  $P_i$  to  $\mathcal{B}_k$ .

Finally, to complete the proof we need to show that  $P_i$  is not included in  $\mathcal{B}_k$  during any instance of  $\Pi_{MM}$  with  $sid'$ , where  $sid' < sid$ . On contrary, if  $P_i$  is included in  $\mathcal{B}_k$  during  $\Pi_{MM}$  with  $sid'$ , where  $sid' < sid$ , then  $P_k$  will never broadcast the  $OK(k, i)$  message during the instance of  $\Pi_{Sh}$  with id sid, which is a contradiction. This is because if  $P_i \in \mathcal{B}_k$ , then all the messages from  $P_i$  are discarded

by  $P_k$  during the instance of  $\Pi_{Sh}$  with id sid, due to the protocol  $\Pi_{MM}$  with id sid.  $\square$

LEMMA 3.4. *For any  $sid \in \mathbb{N}$ , if  $P_D$  is honest, then the view of the adversary is independent of the input  $s$  of  $P_D$  during  $\Pi_{Sh}$  with id sid.*

PROOF. Let  $P_D$  be *honest*. In the protocol,  $P_D$  randomly selects the shares  $s_1, \dots, s_h$ , subject to the condition that  $s_1 + \dots + s_h = s$  holds. Moreover, since each  $S_q = \mathcal{P} \setminus Z_q$  where  $Z_q \in \mathcal{Z}$ , it follows that the probability distribution of the shares learnt by the adversary during  $\Pi_{Sh}$ , will be independent of the input  $s$  of  $P_D$ . More specifically, let  $Z_c \in \mathcal{Z}$  be the set of *corrupt* parties. Then throughout  $\Pi_{Sh}$ , the adversary does not learn anything about the share  $s_c$ , which is available only to the parties in  $S_c = \mathcal{P} \setminus Z_c$ . This is because the share  $s_c$  is distributed by  $P_D$  to the parties in  $S_c$  over pair-wise secure channels. Moreover, during the pair-wise consistency tests, the parties in  $S_c$  exchange the share  $s_c$  only among themselves. It now follows that for every candidate value of  $s$  from the point of view of the adversary, there is a corresponding unique  $s_c$ , which will be consistent with the shares seen by the adversary during  $\Pi_{Sh}$ . Now since the share  $s_c$  is chosen randomly, it follows that the view of the adversary during  $\Pi_{Sh}$  remains independent of  $s$ .  $\square$

LEMMA 3.5. *Protocol  $\Pi_{Sh}$  incurs a communication of  $O(|\mathcal{Z}| \cdot n^2 \log |\mathbb{K}| + n^4 \log n)$  bits, while protocol  $\Pi_{Rec}$  incurs a communication of  $O(|\mathcal{Z}| \cdot n^3 \log |\mathbb{K}|)$  bits.*

PROOF. During  $\Pi_{Sh}$ , the dealer  $P_D$  needs to send a share  $s_q$  of size  $\log |\mathbb{K}|$  bits to each set  $S_q \in \mathbb{S}$ , consisting of  $O(n)$  parties. This requires a communication of  $O(|\mathbb{S}| \cdot n \log |\mathbb{K}|)$  bits. During the pair-wise consistency test, every party in  $S_q$  sends its share to every other party in  $S_q$ , incurring a communication of  $O(|\mathbb{S}| \cdot n^2 \log |\mathbb{K}|)$  bits. There are  $O(n^2)$   $OK(\star, \star)$  messages which are broadcasted, where each message is of size  $2 \log n$  bits, encoding the identity of 2 parties. Moreover,  $P_D$  broadcasts a  $C$  set, encoded using  $O(n \log n)$  bits. During  $\Pi_{Rec}$ , a party may need to broadcast up to  $O(|\mathbb{S}|)$  shares. The communication complexity now follows from the communication complexity of the Acast protocol and the fact that  $|\mathbb{S}| = |\mathcal{Z}|$ .  $\square$

## 4 SCC WITH $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$ CONDITION

The SCC protocol is presented in Fig 3. The protocol is almost the same as the CC protocol of [17] with the following *difference*: while the CC protocol of [17] uses their perfectly-secure AVSS with  $\mathbb{Q}^{(4)}(\mathcal{P}, \mathcal{Z})$  condition, we *replace* the instances of AVSS with our SAVSS scheme with  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition (presented in the last section), thus leading to an SCC with  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition.

The SCC protocol  $\Pi_{SCC}$  consists of two *stages*. In the first stage, a uniformly random, yet *unknown* value  $Coin_i \in \{0, \dots, n-1\}$  is “attached” to every party  $P_i$ . Then, once it is ensured that “sufficiently many” number of parties in a set FS (called *final set*) have been attached with their respective  $Coin$  values, in the second stage, these  $Coin$  values are *publicly* reconstructed, and an output bit is computed taking into account the reconstructed values. However, due to the asynchronous communication, each (honest) party may have a *different* FS set and hence, a potentially different output. To circumvent this problem, the protocol ensures that there is a *non-empty* overlap among the FS sets of all the (honest) parties. Ensuring this common overlap is the crux of the protocol.

During the first stage, each party acts as a dealer and shares a random value from  $\mathbb{K}$  on the behalf of each party, by invoking an instance of  $\Pi_{\text{Sh}}$ . To ensure that each  $\text{Coin}_i \in \{0, \dots, n-1\}$ , the parties set  $\mathbb{K}$  to either a finite ring or a field, where  $|\mathbb{K}| \geq n$ . Each party  $P_i$  creates a dynamic set of *accepted dealers*  $\mathcal{AD}_i$ , which includes all the dealers in whose  $\Pi_{\text{Sh}}$  instances,  $P_i$  computes an output. The properties of  $\Pi_{\text{Sh}}$  guarantee that these dealers are eventually included in the set of accepted dealer of every other honest party as well. Party  $P_i$  then waits for "sufficiently many" number of dealers to be accepted, such that  $\mathcal{AD}_i$  is guaranteed to contain at least one *honest dealer*. For this,  $P_i$  keeps on expanding  $\mathcal{AD}_i$  until  $\mathcal{P} \setminus \mathcal{AD}_i \in \mathcal{Z}$  holds (which eventually happens for an honest  $P_i$ ). Once  $\mathcal{AD}_i$  achieves this property,  $P_i$  assigns  $\mathcal{AD}_i$  to the set  $\text{AD}_i$  and publicly announces the same. This is interpreted as  $P_i$  having *attached* the set of dealers  $\text{AD}_i$  to itself. Then, the summation of the values modulo  $n$ , shared by the dealers in  $\text{AD}_i$  on the behalf of  $P_i$ , is set to be  $\text{Coin}_i$ . Note that the value of  $\text{Coin}_i$  will *not* be known to anyone at this point (including  $P_i$ ), as the value(s) shared by the honest dealer(s) in the set  $\text{AD}_i$  on the behalf of  $P_i$  is(are) not yet known, owing to the *privacy* property of  $\Pi_{\text{Sh}}$ .

On receiving  $\text{AD}_j$  from any  $P_j$ , party  $P_i$  verifies if the set is "valid" by checking if the  $\Pi_{\text{Sh}}$  instances of dealers in  $\text{AD}_j$  has produced an output for  $P_i$  as well; i.e.  $\text{AD}_j \subseteq \mathcal{AD}_i$  holds. Once the validity of  $\text{AD}_j$  is confirmed,  $P_i$  "partially accepts"  $P_j$  and includes it in its set of *partially-accepted parties*  $\mathcal{PAP}_i$ . Additionally,  $P_i$  publicly "approves" the partial-acceptance of  $P_j$ , by broadcasting an OK message for  $P_j$  (this implicitly means  $P_i$ 's approval for the yet unknown, but well-defined value  $\text{Coin}_j$ ). Notice that partial-acceptance of  $P_j$  by  $P_i$  implies that every other honest party will also eventually partially accept  $P_j$ . This is because every other honest party will eventually receive the set  $\text{AD}_j$  and will find it valid.

Party  $P_i$  then waits for the approval of  $\text{AD}_j$  from a set of parties  $S_j$  including itself, such that  $\mathcal{P} \setminus S_j \in \mathcal{Z}$  holds, thus guaranteeing that  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(2)}(S_j, \mathcal{Z})$  condition. Once  $\mathcal{P} \setminus S_j \in \mathcal{Z}$  holds,  $P_j$  is shifted from  $\mathcal{PAP}_i$  to a dynamic set of *accepted parties*  $\mathcal{AP}_i$ . Looking ahead, ensuring that  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(2)}(S_j, \mathcal{Z})$  condition, coupled with maintaining separate  $\mathcal{PAP}_i$  and  $\mathcal{AP}_i$  sets, plays a crucial rule to ensure a *non-empty* overlap among the FS sets of honest parties. Notice that the acceptance of  $P_j$  by  $P_i$  implies the eventual acceptance of  $P_j$  by every other honest party, as the corresponding approval (namely the OK messages) for  $\text{AD}_j$  are publicly broadcasted. Party  $P_i$  keeps on expanding its set of accepted parties  $\mathcal{AP}_i$  until  $\mathcal{P} \setminus \mathcal{AP}_i \in \mathcal{Z}$  holds, which happens eventually. Once ensured,  $P_i$  publicly announces it with a ready message and the corresponding  $\mathcal{AP}_i$  set, denoted by  $\text{AP}_i$ , along with its set of partially-accepted parties  $\mathcal{PAP}_i$ .<sup>2</sup>

On receiving the ready message and  $\text{AP}_j, \mathcal{PAP}_j$  sets from any party  $P_j$ , party  $P_i$  verifies the "validity" of  $\text{AP}_j$  and  $\mathcal{PAP}_j$ . For this,  $P_i$  checks if the parties in  $\text{AP}_j$  are accepted by  $P_i$  as well; i.e. if  $\text{AP}_j \subseteq \mathcal{AP}_i$  holds. And if the partially-accepted parties in  $\mathcal{PAP}_j$  are either accepted or partially-accepted by  $P_i$ ; i.e. if  $\mathcal{PAP}_j \subseteq (\mathcal{AP}_i \cup \mathcal{PAP}_i)$  holds. Upon successful verification,  $P_j$  is included by  $P_i$  in a dynamic set of *supportive parties*  $\mathcal{SP}_i$ . The interpretation

of  $\mathcal{SP}_i$  is that each party in  $\mathcal{SP}_i$  is "supporting" the beginning of the second stage of the protocol, by presenting a "sufficiently large" valid set of accepted and partially-accepted parties (and hence  $\text{Coin}$  values). Notice that the inclusion of  $P_j$  to  $\mathcal{SP}_i$  implies the eventual inclusion of  $P_j$  by every other honest party in its respective  $\mathcal{SP}$  set. Once the set of supportive parties becomes sufficiently large, i.e.  $\mathcal{P} \setminus \mathcal{SP}_i \in \mathcal{Z}$  holds,  $P_i$  sets a boolean indicator  $\text{Flag}_i$  to 1, marking the beginning of the second stage. Let  $\text{SP}_i$  denote the set of supportive parties  $\mathcal{SP}_i$  when  $\text{Flag}_i$  is set to 1.

The second stage involves publicly reconstructing the unknown  $\text{Coin}$  values which were accepted and partially-accepted by  $P_i$  till it sets  $\text{Flag}_i$  to 1. Let  $\text{FS}_i$  be the set of accepted and partially-accepted parties when  $\text{Flag}_i$  is set to 1. This implies that the union of the  $\text{AP}_j$  and  $\mathcal{PAP}_j$  sets of all the parties in  $\text{SP}_i$  is a subset of  $\text{FS}_i$ , as each  $(\text{AP}_j \cup \mathcal{PAP}_j) \subseteq (\mathcal{AP}_i \cup \mathcal{PAP}_i)$ . The parties proceed to reconstruct the value  $\text{Coin}_k$  corresponding to each  $P_k \in \text{FS}_i$ . For this, the parties start executing the corresponding  $\Pi_{\text{Rec}}$  instances, that are required for reconstructing the secrets shared by the accepted dealers  $\text{AD}_k$  on the behalf of  $P_k$ . If any of the  $\text{Coin}_k$  values turns out to be 0, party  $P_i$  sets its output to 0, else, it outputs 1.

To argue that there exists a *non-empty* overlap among the FS sets of the honest parties, we consider the first *honest* party  $P_i$  who broadcasts a ready message and show that the set  $\text{AP}_i$  will be the common overlap (see Lemma 4.3).<sup>3</sup> For the ease of understanding, we pictorially depict the various sets computed in the protocol  $\Pi_{\text{SCC}}$  in Fig 2. Notice that the parties may end up reconstructing a *different* coin value  $\text{Coin}'_k \neq \text{Coin}_k$ , corresponding to  $P_k \in \text{FS}_i$ , which will end up affecting the required success probability of the protocol  $\Pi_{\text{SCC}}$ . However, in this case, at least one *new* local-conflict occurs between an honest and a corrupt party.

#### Protocol $\Pi_{\text{SCC}}(\mathcal{P}, \mathcal{Z})$

1. **Initialization:** Initialize a set of *accepted dealers*  $\mathcal{AD}_i$ , a set of *partially-accepted parties*  $\mathcal{PAP}_i$ , a set of *accepted parties*  $\mathcal{AP}_i$  and a set of *supportive parties*  $\mathcal{SP}_i$  to  $\emptyset$ . Additionally, initialize a Boolean variable  $\text{Flag}_i = 0$ .
2. **Sharing Secrets on Behalf of Others:**
  - For  $j = 1, \dots, n$ , choose a random secret  $s_{ij} \in \mathbb{K}$  on the behalf of  $P_j$ , and as a dealer, invoke an instance  $\Pi_{\text{Sh}}(\mathcal{P}, \mathcal{Z}, \mathbb{S}, P_i, s_{ij})$  of  $\Pi_{\text{Sh}}$  with id  $(\text{id}, P_i, P_j)$ . Let this instance be denoted as  $\Pi_{\text{Sh}}^{(ij)}$ .
  - Participate in  $\Pi_{\text{Sh}}^{(jk)}$ , corresponding to every  $P_j, P_k \in \mathcal{P}$ .
3. **Populating the Set of Accepted Dealers:**
  - Add party  $P_j$  to  $\mathcal{AD}_i$ , if an output is computed in the instances  $\Pi_{\text{Sh}}^{(j1)}, \dots, \Pi_{\text{Sh}}^{(jn)}$ .
  - If  $(\mathcal{P} \setminus \mathcal{AD}_i) \in \mathcal{Z}$ , then assign  $\text{AD}_i = \mathcal{AD}_i$  and broadcast the message  $(\text{Attach}, \text{AD}_i, P_i)$ . The set  $\text{AD}_i$  is considered to be the set of dealers attached to  $P_i$ . Let

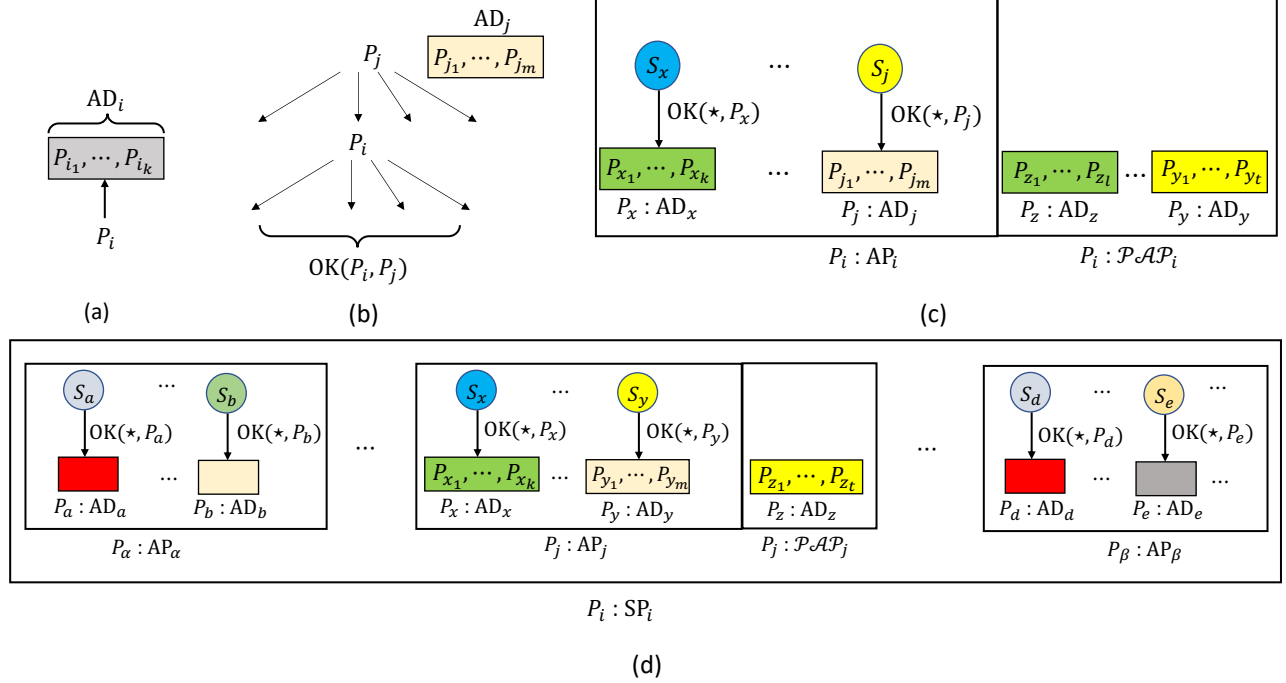

$$\text{Coin}_i \stackrel{\text{def}}{=} \sum_{P_j \in \text{AD}_i} s_{ji} \pmod n.$$

We say that the coin  $\text{Coin}_i$  is attached to party  $P_i$ .<sup>a</sup>

4. **Validating the Set of Accepted Dealers:**
  - If the message  $(\text{Attach}, \text{AD}_j, P_j)$  is received from the broadcast of  $P_j$ , then broadcast a message  $\text{OK}(P_i, P_j)$ , if the dealers

<sup>2</sup>We note that the sets  $\mathcal{AP}_i$  were *not* built in the CC protocol of [17]. However, these sets are *essential* even in their CC protocol, as otherwise a non-empty overlap among the FS sets of honest parties is *not* guaranteed in their CC protocol.

<sup>3</sup>This lemma is borrowed from [17]. However, the proof provided in [17] is flawed, as they *do not* consider the  $\mathcal{PAP}$  sets in their protocol. The proof presented in this article, can be considered as the correct proof of the lemma for their CC protocol.

**Figure 2: Pictorial depiction of the various sets computed in the protocol  $\Pi_{SCC}$ . The set  $AD_i$  in figure (a) denotes the set of dealers attached to  $P_i$ ; the values shared by the parties in  $AD_i$  on the behalf of  $P_i$  define the value  $Coin_i$ . Figure (b) denotes  $P_j$  broadcasting  $AD_j$ . Upon receiving  $AD_j$  from  $P_j$ , party  $P_i$  approves  $AD_j$  through the  $OK(P_i, P_j)$  message. Figure (c) denotes the set of accepted parties  $AP_i$  and the set of partially-accepted parties  $PPA_i$  for  $P_i$ . For every  $P_j \in AP_i$ , there is a corresponding set  $S_j$ , who has approved  $AD_j$  and hence  $Coin_j$ . Finally, figure (d) denotes the set  $SP_i$ .**

- attached to  $P_j$  are accepted by  $P_i$ , i.e.  $AD_j \subseteq AD_i$  holds. Moreover, include  $P_j$  to  $PPA_i$ .
5. **Populating the Set of Accepted Parties:**
    - Shift  $P_j$  from  $PPA_i$  to  $AP_i$ , if  $OK(\star, P_j)$  is received from the broadcast of a set of parties  $S_j$  including  $P_i$ , such that  $(\mathcal{P} \setminus S_j) \in \mathcal{Z}$ .
    - If  $(\mathcal{P} \setminus AP_i) \in \mathcal{Z}$ , then assign  $AP_i = \mathcal{AP}_i$  and broadcast the message  $(ready, P_i, AP_i, PPA_i)$ .
  6. **Populating the Set of Supportive Parties:**
    - Consider  $P_j$  to be *supportive* and include it in  $SP_i$ , if  $P_i$  receives the message  $(ready, P_j, AP_j, PPA_j)$  from the broadcast of  $P_j$  and each party in  $AP_j$  is accepted by  $P_i$  and each party in  $PPA_j$  is either accepted or partially-accepted by  $P_i$ , i.e.  $AP_j \subseteq AP_i$  and  $PPA_j \subseteq (AP_i \cup PPA_i)$  holds.
    - If  $\mathcal{P} \setminus SP_i \in \mathcal{Z}$ , then set  $Flag_i = 1$ . Let  $SP_i$  and  $FS_i$  be the contents of  $SP_i$  and  $(AP_i \cup PPA_i)$  respectively, when  $Flag_i = 1$ .<sup>b</sup>
  7. **Reconstructing the Coin Values:**
    - If  $Flag_i = 1$ , then reconstruct the value of the coin attached to each party in  $FS_i$  as follows:
      - Start participating in the instances  $\Pi_{Rec}(\mathcal{P}, \mathcal{Z}, \mathbb{S}, P_j, s_{jk})$  with id  $(sid, P_j, P_k)$  corresponding to each  $P_j \in AD_k$ , such that  $P_k \in FS_i$ . Denote this instance of  $\Pi_{Rec}$  as  $\Pi_{Rec}^{(jk)}$  and let  $r_{jk}$  be the corresponding output (Some parties may be included in the set  $AP_i \cup PPA_i$  after  $Flag_i$  is set to 1. In that case, start participating in the corresponding  $\Pi_{Rec}$  instances).

- For every  $P_k \in FS_i$ , compute

$$Coin'_k = \sum_{P_j \in AD_k} r_{jk} \pmod n.$$

We say that the value  $Coin'_k$  is associated to  $P_k$ .

#### 8. Output computation:

- If the values associated to all the parties in  $FS_i$  are computed, then do the following.
  - If there exists any  $P_k \in FS_i$  where  $Coin'_k = 0$ , then output 0.
  - Else output 1.

<sup>a</sup>The value of  $Coin_i$  will not be known to anyone at this step, including  $P_i$ .

<sup>b</sup>Note that  $\bigcup_{P_j \in SP_i} (AP_j \cup PPA_j) \subseteq FS_i$  holds, as  $(AP_j \cup PPA_j) \subseteq (AP_i \cup PPA_i)$ .

**Figure 3: The shunning common-coin protocol for session id  $sid$ . The above code is executed by every  $P_i \in \mathcal{P}$**

The properties of  $\Pi_{SCC}$  are stated in the following lemmas and theorem, which are proved in Appendix A due to space constraints.

LEMMA 4.1. *If each honest party participates in  $\Pi_{SCC}$  with id  $sid$ , then each honest party eventually computes an output.*

LEMMA 4.2. *During  $\Pi_{SCC}$  with id  $sid$ , if any honest party receives the message  $(Attach, AD_k, P_k)$  from the broadcast of any party  $P_k$ , then a unique value  $Coin_k$  is fixed such that all the following hold:*

- The coin  $\text{Coin}_k$  is attached to  $P_k$ .
- The value  $\text{Coin}_k$  is distributed uniformly over  $\{0, \dots, n-1\}$  and is independent of the coins attached to the other parties.
- If any honest party associates  $\text{Coin}'_k \neq \text{Coin}_k$  to  $P_k$ , then at least one new local-conflict occurs between an honest and a corrupt party.

LEMMA 4.3. In  $\Pi_{\text{SCC}}$  with  $\text{id sid}$ , once some honest party sets  $\text{Flag}$  to 1, then there exists a set, say  $\mathcal{M}$ , such that all the following hold:

- $\mathcal{P} \setminus \mathcal{M} \in \mathcal{Z}$ .
- For each  $P_j \in \mathcal{M}$ , some honest party receives the message  $(\text{Attach}, \text{AD}_j, P_j)$  from the broadcast of  $P_j$ .
- Whenever any honest party  $P_i$  sets its  $\text{Flag}_i = 1$ , the condition  $\mathcal{M} \subseteq \text{FS}_i$  holds.

LEMMA 4.4. In  $\Pi_{\text{SCC}}$  with  $\text{id sid}$ , one of the following holds.

- For every possible  $\sigma \in \{0, 1\}$ , with probability at least  $\frac{1}{n}$ , all the honest parties output  $\sigma$ ; otherwise
- At least one new local-conflict occurs between an honest and a corrupt party.

LEMMA 4.5. Protocol  $\Pi_{\text{SCC}}$  incurs a communication of  $O(|\mathcal{Z}| \cdot n^5 \log |\mathbb{K}| + n^6 \log n)$  bits.

THEOREM 4.6. Let  $\text{Adv}$  be a computationally unbounded adversary, characterized by an adversary structure  $\mathcal{Z}$ , satisfying the  $\mathcal{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition and where  $|\mathcal{P}| = n \geq 3$ . Then for every possible  $\text{id} \in \mathbb{N}$ , protocol  $\Pi_{\text{SCC}}$  is a  $\frac{1}{n}$ -SCC protocol, incurring a communication of  $O(|\mathcal{Z}| \cdot n^5 \log |\mathbb{K}| + n^6 \log n)$  bits.

## 5 ABA WITH $\mathcal{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$ CONDITION

In this section, we show how to “combine” protocols  $\Pi_{\text{Vote}}$  and  $\Pi_{\text{SCC}}$  to get the protocol  $\Pi_{\text{ABA}}$  (see Fig 4), by generalizing the blueprint of [7, 20, 35] against general adversaries. For an easy description of the blueprint (against *threshold* adversaries), we refer to [3, 11]. The protocol consists of several iterations, where each iteration consists of two instances of  $\Pi_{\text{Vote}}$  protocol and one instance of  $\Pi_{\text{SCC}}$ , which are carefully “stitched” together.

In each iteration, during the first instance of  $\Pi_{\text{Vote}}$ , the parties participate with their “current input”, which is initialized to their respective bits for ABA in the first iteration. Then, independent of the output received from the instance of  $\Pi_{\text{Vote}}$ , the parties participate in an instance of  $\Pi_{\text{SCC}}$ . Next, the parties decide their respective inputs for the second instance of  $\Pi_{\text{Vote}}$  protocol, based on the output they received from the first instance. If a party has received the *highest* grade (namely 2) during the first instance of  $\Pi_{\text{Vote}}$ , then the party *continues* with the bit received from that  $\Pi_{\text{Vote}}$  instance for the second  $\Pi_{\text{Vote}}$  instance. Otherwise, the party *switches* to the output received from  $\Pi_{\text{SCC}}$ . The output from the second  $\Pi_{\text{Vote}}$  instance is then set as the modified input for the next iteration, if it is obtained with a grade higher than 0, else the output of  $\Pi_{\text{SCC}}$  is taken as the modified input for the next iteration.

If during any iteration a party obtains the highest grade from the second instance of  $\Pi_{\text{Vote}}$ , then it indicates this publicly by sending a ready message to every party, along with the bit received. The ready message is an indication for the others about the “readiness” of the sender party to consider the corresponding bit as the output. Finally, once a party receives this readiness indication for a common bit  $b$  from “sufficiently many” parties, then that bit is taken as the

output and the party terminates. To ensure that every other party also outputs the same bit, once it is guaranteed that a party has received the ready message for a common bit from at least one honest party, it itself sends a ready message for the same bit (if it has not done so earlier) to every other party.

The intuition behind the protocol is the following. In the protocol there can be two cases. The *first* case is when all the honest parties start with the *same* input bit, say  $b$ . Then, they will obtain the output  $b$  from all the instances of  $\Pi_{\text{Vote}}$  protocol in all the iterations and the outputs from  $\Pi_{\text{SCC}}$  will be never considered. Consequently, each honest party will eventually send a ready message for  $b$ . Moreover, only corrupt parties may send a ready message for  $1-b$  and hence no honest party ever sends a ready message for  $1-b$ . Hence, each honest party eventually outputs  $b$ .

The *second* case is when the honest parties start the protocol with *different* input bits. In this case, the protocol tries to take the help of  $\Pi_{\text{SCC}}$  to ensure that all honest parties reach an iteration with a common input bit for that iteration. Once such an iteration is reached, this *second* case gets “transformed” to the *first* case and hence all honest parties will eventually output that common bit. In more detail, in each iteration  $k$ , it will be ensured that either every honest party have the same input bit for the second instance of  $\Pi_{\text{Vote}}$  with probability at least  $\frac{1}{n} \cdot \frac{1}{2} = \frac{1}{2n}$  or else one new local-conflict occurs. This is because the input for second instance of  $\Pi_{\text{Vote}}$  is either the output bit of the first instance of  $\Pi_{\text{Vote}}$  or the output of  $\Pi_{\text{SCC}}$ , both of which are *independent* of each other. Hence if the output of  $\Pi_{\text{SCC}}$  is same for all the parties with probability  $\frac{1}{n}$ , then with probability  $\frac{1}{n} \cdot \frac{1}{2}$ , this bit will be the same as output bit from the first instance of  $\Pi_{\text{Vote}}$ . If in any iteration  $k$ , it is *guaranteed* that all honest parties have the same inputs for the second instance of  $\Pi_{\text{Vote}}$ , then the parties will obtain a common output and with highest grade from the second instance of  $\Pi_{\text{Vote}}$ . And then from the next iteration onward, all parties will stick to that common bit and eventually output that common bit.

We show that it requires  $O(n^2)$  number of iterations in *expectation* before a “good” iteration is reached where it is *guaranteed* that all honest parties have the same input for the second instance of  $\Pi_{\text{Vote}}$ . Intuitively, this is because there can be  $O(n^2)$  number of “bad” iterations in which the honest parties may have different outputs from the corresponding instances of  $\Pi_{\text{SCC}}$ . This follows from the fact that the corrupt parties may deviate from the protocol instructions during the instances of  $\Pi_{\text{SCC}}$ . There can be at most  $O(n^2)$  local-conflicts which may occur *overall* during various “failed” instances of  $\Pi_{\text{SCC}}$  (where a failed instance means that different honest parties obtain different outputs) and only after all these local-conflicts are identified, the parties may start witnessing “clean” instances of  $\Pi_{\text{SCC}}$  where all honest parties shun communication from all corrupt parties and where it is ensured that all honest parties obtain the same output bit with probability  $\frac{1}{n}$ . Once all the bad iterations are over and all potential local-conflicts are identified, in each subsequent iteration, all honest parties will then have the same output from  $\Pi_{\text{SCC}}$  (and hence, same input for the second instance of  $\Pi_{\text{Vote}}$ ) with probability at least  $\frac{1}{2n}$ . Consequently, it will take  $\Theta(n^2)$  expected number of such iterations before the parties reach a good iteration where it is guaranteed that all honest parties have the same inputs for the second instance of  $\Pi_{\text{Vote}}$ .

**Protocol  $\Pi_{\text{ABA}}$**

**Input:** Party  $P_i$  has the bit  $b_i$  as input for the ABA protocol.

- **Initialization:** Set  $b = b_i$ ,  $\text{sid} = 0$ ,  $\text{Committed} = \text{False}$  and  $k = 1$ . Then do the following.
  1. Set  $\text{sid} = \text{sid} + 1$  and participate in an instance of  $\Pi_{\text{Vote}}$  protocol with id  $\text{sid}$  and input  $b$ .
  2. Once an output  $(b, g)$  is received from the instance of  $\Pi_{\text{Vote}}$  with id  $\text{sid}$ , participate in an instance of  $\Pi_{\text{SCC}}$  with id  $\text{sid}$ . Let  $\text{Coin}_k$  denote the output received during  $\Pi_{\text{SCC}}$  with id  $\text{sid}$ .
  3. If  $g < 2$ , then set  $b = \text{Coin}_k$ .
  4. Set  $\text{sid} = \text{sid} + 1$  and participate in an instance of  $\Pi_{\text{Vote}}$  protocol with id  $\text{sid}$  and input  $b$  and let  $(b', g')$  be the output received. If  $g' > 0$ , then set  $b = b'$ .
  5. If  $g' = 2$  and  $\text{Committed} = \text{False}$ , then set  $\text{Committed} = \text{True}$  and send  $(\text{ready}, b)$  to all the parties.
  6. Set  $k = k + 1$  and repeat from 1.
- **Output Computation and Termination:**
  - If  $(\text{ready}, b)$  is received from a set of parties  $\mathcal{R} \notin \mathcal{Z}$ , then send  $(\text{ready}, b)$  to all the parties.
  - If  $(\text{ready}, b)$  is received from a set of parties  $\mathcal{T}$  such that  $\mathcal{P} \setminus \mathcal{T} \in \mathcal{Z}$ , then output  $b$  and terminate.

**Figure 4: The ABA protocol from  $\Pi_{\text{Vote}}$  and  $\Pi_{\text{SCC}}$ . The above code is executed by every  $P_i \in \mathcal{P}$**

The properties of  $\Pi_{\text{ABA}}$  are stated in the following lemmas and Theorem, which are proved in Appendix B due to space constraints.

LEMMA 5.1. *In protocol  $\Pi_{\text{ABA}}$ , if all honest parties have the same input bit  $\sigma$ , then all honest parties eventually output  $\sigma$ .*

LEMMA 5.2. *In  $\Pi_{\text{ABA}}$ , if some honest party terminates with output  $\sigma$ , then every other honest party eventually terminates with output  $\sigma$ .*

LEMMA 5.3. *In protocol  $\Pi_{\text{ABA}}$ , if all honest parties initiate iteration  $k$ , then one of the following holds:*

- *With probability at least  $\frac{1}{2n}$ , all honest parties have the same updated bit  $b$  at the end of iteration  $k$ ; or*
- *At least one new local-conflict occurs between an honest and a corrupt party.*

COROLLARY 5.4. *Let  $\mathcal{I}$  denote the set of iterations  $k$  in  $\Pi_{\text{ABA}}$ , such that all the honest parties have the same updated bit after iteration  $k$  with probability less than  $\frac{1}{2n}$ . Then  $|\mathcal{I}| = O(n^2)$ .*

LEMMA 5.5. *In protocol  $\Pi_{\text{ABA}}$ , if for every iteration  $k$ , all the honest parties have the same updated bit at the end of iteration  $k$  with probability at least  $\frac{1}{2n}$ , then the protocol requires expected  $O(n^2)$  iterations to terminate.*

LEMMA 5.6. *Protocol  $\Pi_{\text{ABA}}$  terminates for the honest parties in  $O(n^2)$  expected running time.*

THEOREM 5.7. *Let  $\text{Adv}$  be a computationally unbounded adversary, characterized by an adversary structure  $\mathcal{Z}$ , such that  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition. Then protocol  $\Pi_{\text{ABA}}$  is an almost-surely terminating ABA protocol with expected running time of  $R = O(n^2)$ . The protocol incurs an expected communication complexity of  $O(R \cdot (|\mathcal{Z}| \cdot n^5 \log |\mathbb{K}| + n^6 \log n))$  bits.*

## 1165 A PROPERTIES OF THE PROTOCOL $\Pi_{\text{SCC}}$

1166 In this section, we prove the properties of the protocol  $\Pi_{\text{SCC}}$ .

1167 **LEMMA 4.1.** *If each honest party participates in  $\Pi_{\text{SCC}}$  with id sid,*  
 1170 *then each honest party eventually computes an output.*

1171 **PROOF.** We begin by showing that if all *honest* parties partici-  
 1172 pate in the protocol  $\Pi_{\text{SCC}}$ , then each *honest* party  $P_i$  eventually sets  
 1173  $\text{Flag}_i = 1$ . Firstly, each *honest* party  $P_j$  invokes its  $n$  instances of  
 1174  $\Pi_{\text{Sh}}$  as a dealer. These instances are guaranteed to eventually pro-  
 1175 duce an output for each *honest* party, which follows from Lemma  
 1176 3.2. Hence,  $P_i$  eventually finds a set of accepted-dealers  $\text{AD}_i$  such  
 1177 that  $\mathcal{P} \setminus \text{AD}_i \in \mathcal{Z}$ , as the set of honest parties constitute a poten-  
 1178 tial  $\text{AD}_i$  set. This implies that  $P_i$  eventually broadcasts a message  
 1179  $(\text{Attach}, \text{AD}_i, P_i)$ . Consequently,  $P_i$  eventually receives the mes-  
 1180 sage  $(\text{Attach}, \text{AD}_j, P_j)$  from the broadcast of every *honest* party  $P_j$ .  
 1181 Also,  $\text{AD}_j \subseteq \mathcal{AD}_i$  eventually holds, which again follows from  
 1182 Lemma 3.2. Consequently,  $P_i$  eventually broadcasts a message  
 1183  $\text{OK}(P_i, P_j)$  for every honest party  $P_j$ . Therefore,  $P_i$  eventually in-  
 1184 cludes every honest party in the set of accepted-parties  $\mathcal{AP}_i$ , and  
 1185 eventually  $\mathcal{P} \setminus \mathcal{AP}_i \in \mathcal{Z}$  holds. Hence,  $P_i$  eventually broadcasts a  
 1186 message  $(\text{ready}, P_i, \text{AP}_i)$ . Consequently,  $P_i$  eventually receives the  
 1187 message  $(\text{ready}, P_j, \text{AP}_j)$  from the broadcast of every other honest  
 1188 party  $P_j$ . Also,  $\text{AP}_j \subseteq \mathcal{AP}_i$  eventually holds, which follows from  
 1189 Lemma 3.2. Therefore,  $P_i$ 's set of supportive parties  $\mathcal{SP}_i$  eventually  
 1190 satisfies the condition  $\mathcal{P} \setminus \mathcal{SP}_i \in \mathcal{Z}$ , after which  $P_i$  sets  $\text{Flag}_i = 1$ .

1191 We now show that if any *honest*  $P_i$  sets  $\text{Flag}_i = 1$ , then  $P_i$  even-  
 1192 tually computes an output in  $\Pi_{\text{SCC}}$ . For this to be true, party  $P_i$   
 1193 needs to be able to compute the values  $\text{Coin}_k$  attached with all the  
 1194 parties  $P_k \in \text{FS}_i$ . Party  $P_i$  can compute  $\text{Coin}_k$ , if the  $\Pi_{\text{Rec}}$  instances  
 1195  $\Pi_{\text{Rec}}^{(jk)}$  produce some output for  $P_i$ , corresponding to each  $P_j \in \text{AD}_k$ .  
 1196 We show that the  $\Pi_{\text{Rec}}$  instances  $\Pi_{\text{Rec}}^{(jk)}$  eventually produce an out-  
 1197 put. This follows from the properties of  $\Pi_{\text{Rec}}$  (Lemma 3.2) and the  
 1198 fact that every party  $P_k \in \text{FS}_i$  is eventually accepted or partially-  
 1199 accepted by every other honest party  $P_\ell$  (i.e.,  $P_k \in \mathcal{AP}_\ell \cup \mathcal{PAP}_\ell$ )  
 1200 and consequently  $\Pi_{\text{Rec}}^{(jk)}$  is eventually initiated by every honest  
 1201 party.

1202 Hence, if each honest party participates in protocol  $\Pi_{\text{SCC}}$ , then  
 1203 each honest party eventually computes an output in  $\Pi_{\text{SCC}}$ .  $\square$

1204 We next prove the properties of the  $\text{Coin}$  values, attached with  
 1205 various parties.

1206 **LEMMA 4.2.** *During  $\Pi_{\text{SCC}}$  with id sid, if any honest party receives the*  
 1207 *message  $(\text{Attach}, \text{AD}_k, P_k)$  from the broadcast of any party  $P_k$ , then*  
 1208 *a unique value  $\text{Coin}_k$  is fixed such that all the following hold:*

- 1209 – The coin  $\text{Coin}_k$  is attached to  $P_k$ .
- 1210 – The value  $\text{Coin}_k$  is distributed uniformly over  $\{0, \dots, n-1\}$  and  
 1211 is independent of the coins attached to the other parties.
- 1212 – Any honest party associates  $\text{Coin}'_k \neq \text{Coin}_k$  to  $P_k$ , then at least  
 1213 one new local-conflict occurs between an honest and a corrupt  
 1214 party.

1219 **PROOF.** Let  $P_i$  be an *honest* party, who receives the message  
 1220  $(\text{Attach}, \text{AD}_k, P_k)$  from the broadcast of  $P_k$ . From the properties  
 1221 of broadcast, every honest party eventually receives the same mes-  
 1222 sage  $(\text{Attach}, \text{AD}_k, P_k)$  from the broadcast of  $P_k$ . Let  $\{s_{jk}\}_{P_j \in \text{AD}_k}$   
 1223 denote the set of values shared by  $P_j \in \text{AD}_k$  (as a dealer), on the  
 1224 behalf of  $P_k$ , during the instance  $\Pi_{\text{Sh}}^{(jk)}$ . We define

$$1225 \text{Coin}_k \stackrel{\text{def}}{=} \sum_{P_j \in \text{AD}_k} s_{jk} \pmod n. \quad 1226$$

1227 Since all the honest parties receive the same set  $\text{AD}_k$ , the value of  
 1228  $\text{Coin}_k$  will be common from the point of view of all honest parties.

1229 For the second property, we note that the parties start executing  
 1230 the instances  $\{\Pi_{\text{Rec}}^{(jk)}\}_{P_j \in \text{AD}_k}$  only after receiving the broadcasted  
 1231 message  $(\text{Attach}, \text{AD}_k, P_k)$ . This implies that the set  $\text{AD}_k$  is fixed,  
 1232 before any instance in  $\{\Pi_{\text{Rec}}^{(jk)}\}_{P_j \in \text{AD}_k}$  is invoked. The set  $\text{AD}_k$   
 1233 consists of at least one *honest* party, say  $P_j$ , as  $\mathcal{P} \setminus \text{AD}_k \in \mathcal{Z}$   
 1234 and  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition. The privacy property  
 1235 of  $\Pi_{\text{Sh}}$  (see Lemma 3.4) ensures that the view of the adversary  
 1236 during the instance of  $\Pi_{\text{Sh}}^{(jk)}$  is independent of the secret  $s_{jk}$  shared  
 1237 by  $P_j$ . Now since the secrets shared by the *honest* parties during  
 1238  $\Pi_{\text{SCC}}$  are mutually independent and uniformly selected from  $\mathbb{K}$ , it  
 1239 follows that  $\text{Coin}_k$  is uniformly and independently distributed over  
 1240  $\{0, \dots, n-1\}$ .

1241 For the third property, let  $P_h$  be an *honest* party, who associates  
 1242  $\text{Coin}'_k$  to  $P_k$ , such that  $\text{Coin}'_k \neq \text{Coin}_k$ . From the protocol steps,  
 1243  $P_h$  associates  $\text{Coin}'_k$  by participating in the instances  $\Pi_{\text{Rec}}^{(jk)}$  and  
 1244 computing the values  $\{r_{jk}\}_{P_j \in \text{AD}_k}$ . Since  $\text{Coin}'_k \neq \text{Coin}_k$ , it follows  
 1245 that  $\{s_{jk}\}_{P_j \in \text{AD}_k} \neq \{r_{jk}\}_{P_j \in \text{AD}_k}$ . Hence, there exists at least one  
 1246  $P_j \in \text{AD}_k$ , such that the value  $s_{jk}$  during the instance  $\Pi_{\text{Sh}}^{(jk)}$  is  
 1247 different from the value  $r_{jk}$  computed during the instance  $\Pi_{\text{Rec}}^{(jk)}$ .  
 1248 The proof now follows from Lemma 3.3.  $\square$

1249 We next prove the crucial non-empty overlap property among  
 1250 the FS of all the honest parties, which will further lead to a *non-zero*  
 1251 success probability for the protocol  $\Pi_{\text{SCC}}$ .

1252 **LEMMA 4.3.** *In protocol  $\Pi_{\text{SCC}}$  with id sid, once some honest party*  
 1253 *sets its  $\text{Flag}$  to 1, then there exists a set, say  $\mathcal{M}$ , such that all the*  
 1254 *following hold:*

- 1255 –  $\mathcal{P} \setminus \mathcal{M} \in \mathcal{Z}$ .
- 1256 – For each  $P_j \in \mathcal{M}$ , some honest party receives the message  
 1257  $(\text{Attach}, \text{AD}_j, P_j)$  from the broadcast of  $P_j$ .
- 1258 – Whenever any honest party  $P_i$  sets its  $\text{Flag}_i = 1$ , the condition  
 1259  $\mathcal{M} \subseteq \text{FS}_i$  holds.

1260 **PROOF.** Let  $P_f$  be the *first* honest party who broadcasts a ready  
 1261 message (from the proof of Lemma 4.1, such a party  $P_f$  exists). This  
 1262 implies that  $P_f$  finds a set of accepted parties  $\text{AP}_f$  (and probably, an  
 1263 additional set of parties  $\mathcal{PAP}_f$ ), such that  $\mathcal{P} \setminus \text{AP}_f \in \mathcal{Z}$ . Moreover,  
 1264 for each  $P_j \in \text{AP}_f$ , party  $P_f$  receives  $\text{OK}(\star, P_j)$  messages from a  
 1265 set of parties  $S_j$ , including  $P_f$ , such that  $\mathcal{P} \setminus S_j \in \mathcal{Z}$ . We define  
 1266  $\mathcal{M} \stackrel{\text{def}}{=} \text{AP}_f$  and show that  $\text{AP}_f$  satisfies all the properties of  $\mathcal{M}$ , as  
 1267 stated in the lemma.

1268 The first property holds as  $\mathcal{P} \setminus \text{AP}_f \in \mathcal{Z}$  holds, before any *honest*  
 1269 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1270 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1271 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1272 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1273 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1274 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1275 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1276 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1277 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1278 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1279 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1280 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1281 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1282 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1283 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1284 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1285 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1286 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1287 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1288 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1289 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1290 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1291 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1292 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1293 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1294 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1295 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1296 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1297 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1298 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1299 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1300 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1301 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1302 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1303 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1304 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1305 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1306 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1307 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1308 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1309 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1310 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1311 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1312 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1313 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1314 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1315 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1316 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1317 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1318 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1319 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1320 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1321 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1322 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1323 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1324 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1325 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1326 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1327 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1328 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1329 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1330 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1331 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1332 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1333 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1334 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1335 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1336 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1337 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1338 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1339 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1340 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1341 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1342 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1343 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1344 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1345 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1346 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1347 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1348 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1349 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1350 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1351 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1352 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1353 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1354 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1355 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1356 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1357 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1358 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1359 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1360 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1361 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1362 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1363 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1364 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1365 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1366 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1367 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1368 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1369 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1370 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1371 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1372 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1373 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1374 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1375 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1376 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1377 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1378 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1379 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1380 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1381 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1382 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1383 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1384 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1385 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1386 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1387 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1388 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1389 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1390 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1391 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1392 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1393 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1394 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1395 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1396 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1397 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1398 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1399 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1400 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1401 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1402 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1403 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1404 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1405 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1406 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1407 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1408 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1409 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1410 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1411 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1412 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1413 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1414 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1415 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1416 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1417 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1418 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1419 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1420 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1421 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1422 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1423 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1424 party  $P_i$  sets  $\text{Flag}_i = 1$ . This follows from the fact that for an *honest*  
 1425 party  $P_i$

$P_i$  to set  $\text{Flag}_i = 1$ , it must receive a ready message from at least one honest party, and  $P_f$  is assumed to be the first honest party that broadcasts a ready message. And  $P_f$  broadcasts the ready message only when  $\mathcal{P} \setminus \text{AP}_f \in \mathcal{Z}$  holds.

We now consider the second property. For each  $P_j \in \text{AP}_f$ , the messages  $\text{OK}(\star, P_j)$  are received from the broadcasts of parties in the set  $S_j$ , which also includes  $P_f$ . Now  $P_f$  broadcasts  $\text{OK}(P_f, P_j)$  only after receiving  $(\text{Attach}, \text{AD}_j, P_j)$  from the broadcast of  $P_j$ . Since  $P_f$  is assumed to be an honest party, the second property follows.

We now consider the third property. Let  $P_i$  be an arbitrary honest party who sets  $\text{Flag}_i$  to 1. We want to show that  $\text{AP}_f \subseteq \text{FS}_i$  holds. For this, consider an arbitrary party  $P_j \in \text{AP}_f$ ; we show that  $P_j$  belongs to  $\text{FS}_i$  as well. Since  $P_j \in \text{AP}_f$ , it implies that  $P_f$  has received the messages  $\text{OK}(\star, P_j)$  from a set of parties  $S_j$ , such that  $\mathcal{P} \setminus S_j \in \mathcal{Z}$  holds. We also note that from the definition of  $\text{SP}_i$ , the condition  $\mathcal{P} \setminus \text{SP}_i \in \mathcal{Z}$  holds. Since  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition, it follows that  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(1)}(S_j \cap \text{SP}_i, \mathcal{Z})$  condition and hence there exists at least one honest party, say  $P_h$ , such that  $P_h \in S_j \cap \text{SP}_i$  holds. Now  $P_h \in S_j$  implies that  $P_h$  must have received the message  $(\text{Attach}, \text{AD}_j, P_j)$  from the broadcast of  $P_j$  and after verification, have broadcasted an  $\text{OK}(P_h, P_j)$  message and included  $P_j$  to  $\mathcal{P}\mathcal{A}\mathcal{P}_h$ . Moreover, since  $P_f$  is assumed to be the first honest party to have broadcasted a ready message, it follows that  $P_j$  will be present in  $\mathcal{P}\mathcal{A}\mathcal{P}_h \cup \text{AP}_h$ , when  $P_h$  broadcasts the message  $(\text{ready}, P_h, \text{AP}_h, \mathcal{P}\mathcal{A}\mathcal{P}_h)$ . Since  $P_h \in \text{SP}_i$ , we have  $(\text{AP}_h \cup \mathcal{P}\mathcal{A}\mathcal{P}_h) \subseteq \text{FS}_i$ . Consequently,  $P_j \in \text{FS}_i$ . This proves the third property.  $\square$

LEMMA 4.4. In protocol  $\Pi_{\text{SCC}}$  with id sid, one of the following holds.

- For every possible  $\sigma \in \{0, 1\}$ , with probability at least  $\frac{1}{n}$ , all the honest parties output  $\sigma$ ; otherwise
- At least one new local-conflict occurs between an honest and a corrupt party.

PROOF. Let  $P_i$  be an arbitrary honest party. In the protocol,  $P_i$  sets its output bit based on the values associated with the parties in  $\text{FS}_i$ . Moreover, for every  $P_k \in \text{FS}_i$ , party  $P_i$  receives the message  $(\text{Attach}, \text{AD}_k, P_k)$  from the broadcast of  $P_k$ . This further guarantees that a uniformly random and independently distributed value  $\text{Coin}_k \in \{0, \dots, n-1\}$  is fixed, which is attached to  $P_k$  (Lemma 4.2). Moreover, let  $\text{Coin}'_k$  be the value, associated to  $P_k$  by  $P_i$ . Furthermore, let  $\mathcal{M}$  be the set of parties as discussed in Lemma 4.3. From the same lemma, it holds that  $\mathcal{M} \subseteq \text{FS}_i$ . Now there are two possible cases.

1. **Case I: For every  $P_k \in \text{FS}_i$ , party  $P_i$  associates  $\text{Coin}'_k = \text{Coin}_k$  to  $P_k$ .** If  $\text{Coin}_k = 0$  holds for some  $P_k \in \mathcal{M}$ , then party  $P_i$  outputs 0 in  $\Pi_{\text{SCC}}$ . The probability that for at least one party  $P_k \in \mathcal{M}$ , the attached value  $\text{Coin}_k = 0$  is  $1 - (1 - \frac{1}{n})^{|\mathcal{M}|} \geq \frac{1}{n}$ . On the other hand, if  $\text{Coin}_k \neq 0$  for every party  $P_k \in \text{FS}_i$ , then  $P_i$  outputs  $\sigma = 1$ . The probability of this event is at least  $(1 - \frac{1}{n})^n \geq e^{-1} \geq 0.36$ . And for any  $n \geq 3$ , we have  $0.36 > \frac{1}{n}$ . This proves the first part of the lemma.
2. **Case II: There exists at least one  $P_k \in \text{FS}_i$ , such that party  $P_i$  associates  $\text{Coin}'_k \neq \text{Coin}_k$  to  $P_k$ .** In this case, from

the third part of Lemma 4.2, at least one new local-conflict occurs. This proves the second part of the lemma.  $\square$

LEMMA 4.5. Protocol  $\Pi_{\text{SCC}}$  incurs a communication of  $O(|\mathcal{Z}| \cdot n^5 \log |\mathbb{K}| + n^6 \log n)$  bits.

PROOF. The proof simply follows from the communication complexity of  $\Pi_{\text{Sh}}$  and  $\Pi_{\text{Rec}}$  (Lemma 3.5) and the fact that there are  $O(n^2)$  instances of  $\Pi_{\text{Sh}}$  and  $\Pi_{\text{Rec}}$  involved in the protocol.  $\square$

The proof of Theorem 4.6 now simply follows from Lemma 4.1-4.5.

THEOREM 4.6. Let Adv be a computationally unbounded adversary, characterized by an adversary structure  $\mathcal{Z}$ , satisfying the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition and where  $|\mathcal{P}| = n \geq 3$ . Then for every possible  $\text{sid} \in \mathbb{N}$ , protocol  $\Pi_{\text{SCC}}$  is a  $\frac{1}{n}$ -SCC protocol, incurring a communication of  $O(|\mathcal{Z}| \cdot n^5 \log |\mathbb{K}| + n^6 \log n)$  bits.

## B PROPERTIES OF THE PROTOCOL $\Pi_{\text{ABA}}$

In this section, we prove the properties of the protocol  $\Pi_{\text{ABA}}$ . We first start with the proof of the validity property.

LEMMA 5.1. In protocol  $\Pi_{\text{ABA}}$ , if all honest parties have the same input bit  $\sigma$ , then all honest parties eventually output  $\sigma$ .

PROOF. Let  $Z_c \in \mathcal{Z}$  be the set of corrupt parties. If every honest party has the same input bit  $\sigma$ , then from the properties of the protocol  $\Pi_{\text{Vote}}$ , all honest parties eventually output  $(b, g) = (\sigma, 2)$  at the end of the first as well as second instance of the  $\Pi_{\text{Vote}}$  protocol during the first iteration. Consequently, every honest party eventually sends a  $(\text{ready}, \sigma)$  message to all the parties and only the parties in  $Z_c$  may send a  $(\text{ready}, \bar{\sigma})$  message. It now follows easily from the steps of the output computation stage that no honest party ever sends a  $(\text{ready}, \bar{\sigma})$  message and all honest parties eventually output  $\sigma$ .  $\square$

We next prove the agreement property.

LEMMA 5.2. In protocol  $\Pi_{\text{ABA}}$ , if some honest party terminates with output bit  $\sigma$ , then every other honest party eventually terminates with output  $\sigma$ .

PROOF. We first show that if any honest party broadcasts a  $(\text{ready}, \sigma)$  message for any  $\sigma \in \{0, 1\}$  during any iteration  $k$ , then no honest party broadcasts a  $(\text{ready}, \bar{\sigma})$  message during iteration  $k$  or in the subsequent iterations. For this, let  $P_i$  be an honest party who broadcasts a  $(\text{ready}, \sigma)$  message during iteration  $k$ . This implies that  $P_i$  outputs  $(b, g) = (\sigma, 2)$  in the second instance of the  $\Pi_{\text{Vote}}$  protocol during iteration  $k$  and sets Committed to True. Then, from the properties of the protocol  $\Pi_{\text{Vote}}$ , every other honest party outputs either  $(\sigma, 2)$  or  $(\sigma, 1)$  in the second instance of the  $\Pi_{\text{Vote}}$  protocol during iteration  $k$ . Consequently, no other honest party broadcasts the  $(\text{ready}, \bar{\sigma})$  message during iteration  $k$ . Also, from the protocol steps, all honest parties update their input to  $\sigma$  for the next iteration. This further implies that all honest parties will continue to input  $\sigma$  to each subsequent invocations of  $\Pi_{\text{Vote}}$ , ignoring the output

of  $\Pi_{\text{SCC}}$ , for as long as they continue running. Consequently, no honest party ever sends a  $(\text{ready}, \bar{\sigma})$  message.

Now let some *honest* party, say  $P_h$ , terminate  $\Pi_{\text{ABA}}$  with output  $\sigma$  during iteration  $k$ . This implies that  $P_h$  receives the  $(\text{ready}, \sigma)$  message from a set of parties  $\mathcal{T}$ , such that  $\mathcal{P} \setminus \mathcal{T} \in \mathcal{Z}$ . Let  $Z_c \in \mathcal{Z}$  be the set of *corrupt* parties. Since all the parties in  $\mathcal{T} \setminus Z_c$  are *honest*, the  $(\text{ready}, \sigma)$  messages of all the parties in  $\mathcal{T} \setminus Z_c$  are eventually delivered to every honest party, during iteration  $k$ . Moreover, as shown above, no honest party ever broadcasts a  $(\text{ready}, \bar{\sigma})$  message. Furthermore, since  $\mathcal{Z}$  satisfies the  $\mathcal{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition, it follows that  $\mathcal{Z}$  satisfies the  $\mathcal{Q}^{(1)}(\mathcal{T} \setminus Z_c, \mathcal{Z})$  condition and consequently  $\mathcal{T} \setminus Z_c \notin \mathcal{Z}$ . Now based on all these, we conclude that every honest party (including  $P_h$ ) eventually broadcasts a  $(\text{ready}, \sigma)$  message during iteration  $k$ , which are eventually delivered to every honest party. Consequently, every honest party eventually receives sufficiently many number of  $(\text{ready}, \sigma)$  messages and terminates with output  $\sigma$ .  $\square$

We next prove that at the end of each iteration, the updated value of all honest parties will be the same with probability at least  $\frac{1}{2n}$ , or at least one *new* local-conflict occurs.

LEMMA 5.3. *In protocol  $\Pi_{\text{ABA}}$ , if all honest parties initiate iteration  $k$ , then one of the following holds:*

- With probability at least  $\frac{1}{2n}$ , all honest parties have the same updated bit  $b$  at the end of iteration  $k$ ; or
- At least one *new* local-conflict occurs between an honest and a corrupt party.

PROOF. We first note that if  $P_i$  is *honest* and if at all any local conflict  $(P_i, P_j)$  occurs during iteration  $k$  of  $\Pi_{\text{ABA}}$ , then the conflict is different from any local conflict of the form  $(P_i, \star)$ , which could have occurred during any iteration  $k'$  of  $\Pi_{\text{ABA}}$ , where  $k' < k$ . On contrary, let the local conflict  $(P_i, P_j)$  occurs both during iteration  $k'$  as well as  $k$ . Since the conflict occurs during the iteration  $k'$ , it follows that during the instance of  $\Pi_{\text{SCC}}$  with id  $k'$ , party  $P_i$  includes  $P_j$  to the set  $\mathcal{B}_i$  as part of one of the underlying memory management protocols. As a result, any communication from party  $P_j$  is completely ignored by  $P_i$  in any instance of  $\Pi_{\text{SCC}}$  protocol with id  $k$ , where  $k > k'$ . Consequently, the local conflict  $(P_i, P_j)$  does not re-occur during iteration  $k$ , which is a contradiction.

Now to prove the lemma statement, we consider an event *Agree*, which denotes that all honest parties have the same input for the second instance of  $\Pi_{\text{Vote}}$  during iteration  $k$ . If the event *Agree* occurs, then from the properties of  $\Pi_{\text{Vote}}$ , all honest parties will have the same updated bit at the end of iteration  $k$ . We show that either the event *Agree* occurs during iteration  $k$  with probability at least  $\frac{1}{2n}$ , or else at least one *new* local-conflict occurs. For this, we consider two different possible cases with respect to the output from the first instance of  $\Pi_{\text{Vote}}$  during iteration  $k$ .

- *Case I: No honest party obtains an output  $(b, 2)$  for any  $b \in \{0, 1\}$  during the first instance of  $\Pi_{\text{Vote}}$ .* In this case, all honest parties set the output from the instance of  $\Pi_{\text{SCC}}$  with id  $k$  as the input for the second instance of  $\Pi_{\text{Vote}}$ . From Lemma 4.4, either all honest parties will have the same output bit from the instance of  $\Pi_{\text{SCC}}$  with probability at least  $\frac{1}{n} > \frac{1}{2n}$ , or at least one *new* local-conflict occurs.

- *Case II: Some honest party obtains an output  $(b, 2)$  during the first instance of  $\Pi_{\text{Vote}}$ .* In this case, the properties of  $\Pi_{\text{Vote}}$  ensure that all honest parties obtain the output  $(b, 2)$  or  $(b, 1)$  from the first instance of  $\Pi_{\text{Vote}}$ . Moreover, from the protocol steps, the output of the instance of  $\Pi_{\text{SCC}}$  with id  $k$  is *not* revealed, until the first honest party generates an output from the first instance of  $\Pi_{\text{Vote}}$  during iteration  $k$ . Consequently, the output bit  $b$  from the first instance of  $\Pi_{\text{Vote}}$  is *independent* of the output of  $\Pi_{\text{SCC}}$ . From Lemma 4.4, either all honest parties will have the same output bit from the instance of  $\Pi_{\text{SCC}}$  with probability at least  $\frac{1}{n}$ , or at least one *new* local-conflict occurs. If all honest parties have the same output  $\text{Coin}_k$  from the instance of  $\Pi_{\text{SCC}}$  with probability at least  $\frac{1}{n}$ , then the probability that  $\text{Coin}_k = b$  holds is at least  $\frac{1}{2} \cdot \frac{1}{n} = \frac{1}{2n}$  and all honest parties will have the same input for the second instance of  $\Pi_{\text{Vote}}$ .  $\square$

As a corollary of Lemma 5.3, we can conclude that there can be  $O(n^2)$  iterations where the honest parties have the same updated value at the end with probability *strictly less* than  $\frac{1}{2n}$ . This is because there are  $O(n^2)$  different local-conflicts which can occur throughout  $\Pi_{\text{ABA}}$ . From Lemma 5.3, if the honest parties do not have the same updated value at the end of an iteration with probability  $\frac{1}{2n}$  or more, then at least one *new* local-conflict occurs. Hence there can be  $O(n^2)$  such iterations.

COROLLARY 5.4. *Let  $\mathcal{I}$  denote the set of iterations  $k$  in  $\Pi_{\text{ABA}}$ , such that all the honest parties have the same updated bit after iteration  $k$  with probability less than  $\frac{1}{2n}$ . Then  $|\mathcal{I}| = O(n^2)$ .*

We next derive the expected number of iterations required in the protocol  $\Pi_{\text{ABA}}$  for the honest parties to produce an output. We begin with the simpler case, where we assume that at the end of *each* iteration of  $\Pi_{\text{ABA}}$ , all honest parties have the *same* updated modified bit. Later, we will derive the expected number of iterations required when this is *not* the case.

LEMMA 5.5. *In protocol  $\Pi_{\text{ABA}}$ , if for every iteration  $k$ , all the honest parties have the same updated bit at the end of iteration  $k$  with probability at least  $\frac{1}{2n}$ , then the protocol requires expected  $O(n^2)$  iterations to terminate.*

PROOF. In order to prove the lemma, we need to derive the expected number of iterations, until all the honest parties have the same input during the second instance of  $\Pi_{\text{Vote}}$  of an iteration. This is because once all the honest parties have the same input during the second instance of  $\Pi_{\text{Vote}}$  of an iteration, then all honest parties will set *Committed* to *True* at the end of that iteration and start broadcasting a *ready* message, followed by terminating the protocol. Let  $\tau$  be the random variable which counts the number of iterations until all honest parties have the same input during the second instance of  $\Pi_{\text{Vote}}$  in an iteration. Then the probability that

$\tau = k$  is given as:

$$\begin{aligned} \Pr(\tau = k) &= \Pr(\tau \neq 1) \cdot \Pr(\tau \neq 2 \mid \tau \neq 1) \cdot \dots \cdot \\ &\Pr(\tau \neq (k-1) \mid \tau \neq 1 \cap \dots \cap \tau \neq (k-2)) \\ &\cdot \Pr(\tau = k \mid \tau \neq 1 \cap \dots \cap \tau \neq (k-1)). \end{aligned}$$

Now as per the lemma condition, every multiplicand on the right hand side in the above equation, except the last one, is upper bounded by  $(1 - \frac{1}{2n})$  and the last multiplicand is upper bounded by  $\frac{1}{2n}$ . Hence, we get

$$\Pr(\tau = k) \leq (1 - \frac{1}{2n})^{k-1} (\frac{1}{2n}).$$

Now the expected value  $E(\tau)$  of  $\tau$  is computed as follows:

$$\begin{aligned} E(\tau) &= \sum_{k=0}^{\infty} \tau \cdot \Pr(\tau = k) \\ &\leq \sum_{k=0}^{\infty} k (1 - \frac{1}{2n})^{k-1} (\frac{1}{2n}) \\ &= \frac{1}{2n} \sum_{k=0}^{\infty} k (1 - \frac{1}{2n})^{k-1} \\ &= \frac{1}{1 - (1 - \frac{1}{2n})} + \frac{1 - \frac{1}{2n}}{(1 - (1 - \frac{1}{2n}))^2} \\ &= 2n + 4n^2 - 2n = 4n^2 \end{aligned}$$

The expression for  $E(\tau)$  is a sum of AGP up to infinite terms, which is given by  $\frac{a}{1-r} + \frac{dr}{(1-r)^2}$ , where  $a = 1$ ,  $r = 1 - \frac{1}{2n}$  and  $d = 1$ . Hence, we have  $E(\tau) \leq 4n^2$ .  $\square$

We next derive the expected number of iterations required in the protocol  $\Pi_{ABA}$ . This automatically gives the expected running time of  $\Pi_{ABA}$ , as each iteration in  $\Pi_{ABA}$  requires a constant time.

LEMMA 5.6. *Protocol  $\Pi_{ABA}$  terminates for the honest parties in  $O(n^2)$  expected running time.*

PROOF. From Corollary 5.4, there can be  $O(n^2)$  iterations in  $\Pi_{ABA}$ , where at the end of the iteration, the updated bits of the honest parties are different with probability more than  $\frac{1}{2n}$ . After this, in each iteration of  $\Pi_{ABA}$ , the honest parties will have the same updated bit at the end of iteration, except with probability at most  $\frac{1}{2n}$  and as a result,  $\Pi_{ABA}$  will require expected  $O(n^2)$  iterations to terminate (follows from Lemma 5.5). As each iterations in  $\Pi_{ABA}$  requires a constant time, it follows that  $\Pi_{ABA}$  terminates for the honest parties in  $O(n^2)$  expected running time.  $\square$

The proof of Theorem 5.7 now follows from Lemmas 5.1-5.6. The communication complexity follows from the fact that two instances of  $\Pi_{Vote}$  and one instance of  $\Pi_{SCC}$  is executed in each iteration in  $\Pi_{ABA}$  and the expected number of such iterations is  $O(n^2)$ .

THEOREM 5.7. *Let Adv be a computationally unbounded adversary, characterized by an adversary structure  $\mathcal{Z}$ , such that  $\mathcal{Z}$  satisfies the  $\mathbb{Q}^{(3)}(\mathcal{P}, \mathcal{Z})$  condition. Then protocol  $\Pi_{ABA}$  is an almost-surely terminating ABA protocol with expected running time of  $R = O(n^2)$ . The protocol incurs an expected communication complexity of  $O(R \cdot (|\mathcal{Z}| \cdot n^5 \log |\mathbb{K}| + n^6 \log n))$  bits.*
