Received: date / Accepted: date

**Abstract** We continue the study of blockcipher-based (tweakable) correlation robust hash functions, which are central building blocks of circuit garbling and oblivious-transfer extension schemes. As results, we first enhance the multiuser tweakable correlation robust notion of Guo et al. (CRYPTO 2020) with a *key leaking oracle* that tells the adversary whether a certain user key satisfies the adversarially-chosen predicate. We then investigate the state-of-the-art hash construction of Guo et al. with respect to our new security definition, providing security proof as well as matching attacks. As an application, we exhibit an OT extension protocol with non-trivial multi-user security.

Keywords Correlation robust hashing  $\cdot$  key leakage  $\cdot$  oblivious-transfer extension

## **1** Introduction

(Tweakable) Correlation robust hashing. Garbling [30,2] and oblivious-transfer (OT) extension [15] are two important building blocks of secure computation protocols. A huge proposition of the proposed schemes were built upon the socalled correlation robust hash functions. This notion was first proposed by Ishai et al. [15] for the purpose of OT extension. Roughly, a hash function H is correlation robust, if the function  $f_R(x) := H(x \oplus R)$  keyed by R is pseudorandom. This notion was soon adopted by garbling with "free-XOR" technique [18]. However, Choi et al. [8] pointed out that a form of "circularity" is needed in order to support security proofs for the "free-XOR" garbling. They proposed circular correlation robustness, which requires  $f_R(x, b) := H(x \oplus R) \oplus b \cdot R$  to be pseudorandom (provided that the input x is never repeated).

Bellare et al. [1] proposed to use fixed-key AES in circuit garbling, which results in substantially reduced CPU time costs. This has motivated many subsequent works to use fixed-key AES in secure computations. Concretely, many of them built their protocols over some variants of correlation robust hashing (e.g., the half-gate garbling scheme [31] used a variant termed circular correlation robustness for naturally derived keys), and then instantiated the hashing using fixed-key AES. To have a solid foundation, Guo et al. [12] provided a systematic study of the correlation robustness notions. They provided detailed security proofs for the correlation robustness of the folklore construction  $\mathsf{MMO}^{\pi}(x) = \pi(x) \oplus x$  and circular correlation robustness of  $MMO_{\sigma}(x) = \pi(\sigma(x)) \oplus \sigma(x)$  using a linear orthomorphism  $\sigma^{1}$ . They proposed a further enhanced notion named tweakable circular correlation robustness (TCCR), which is necessary for the malicious security of some protocols. Roughly,  $H : \{0,1\}^n \times \{0,1\}^t \to \{0,1\}^n$  is TCCR, if  $f_R(w,b,i) :=$  $H(w \oplus R, i) \oplus b \cdot R$  is pseudorandom. Guo et al. [12] also gave a provably secure construction  $\mathsf{TMMO}^{\pi}(x,i) = \pi(\pi(x) \oplus i) \oplus \pi(x)$  using two fixed-key AES calls. Subsequently, Chen and Tessaro [7] proposed two new TCCR hash designs from permutations, including a one-call construction using a field multiplication and a two-call construction with better security against a limited class of distinguishers.

To address security issues due to en mass deployment, Guo et al. [11] initiated the study of multi-user security of TCCR (miTCCR) hash functions. They also leveraged the "birthday-bound" issue in the MMO<sup> $\pi$ </sup> and TMMO<sup> $\pi$ </sup> constructions to attack certain instantiations of half-gate garbling. To remedy, Guo et al. reverted to the "full-fledged" blockcipher  $E : \{0,1\}^n \times \{0,1\}^n \rightarrow$  $\{0,1\}^n$  and proposed  $\widehat{\mathsf{MMO}}^E(x,i) := E(i,\sigma(x))\oplus\sigma(x)$ , where  $\sigma$  is a linear orthomorphism. They proved good miTCCR security bounds: if the distinguisher makes at most  $\mu$  queries per tweak (across multiple users), then secu-

<sup>&</sup>lt;sup>1</sup>  $\sigma$  is linear if  $\sigma(x\oplus y) = \sigma(x)\oplus\sigma(y)$  for all  $x, y \in \{0,1\}^k$ ;  $\sigma$  is an orthomorphism [4] if it is a permutation, and the function  $\sigma'$  given by  $\sigma'(x) := \sigma(x)\oplus x$  is also a permutation. It has been known [4,11] that  $\sigma$  can be efficiently instantiated as  $\sigma(x_L || x_R) = x_R \oplus x_L || x_L$ where  $x_L$  and  $x_R$  are the left and right halves of the input.

rity is ensured up to roughly  $2^n/\mu$  queries to E and  $2^n/\mu$  queries to  $f_R$ . In practical applications  $\mu$  can be limited to o(n) by using random initialization vectors [11], and the security is thus nearly optimal. Due to this,  $\widehat{\mathsf{MMO}}^E$  has been adopted by some [6], even if its key schedule invocations slightly decreases performance.

Selective-failure leakage on keys. In the active setting where an adversary can arbitrarily deviate from the protocol, almost all existing OT-extension protocols (e.g., [17,20,24,3,29,27,23,9]), to generate correlated OT correlations (modeled as an ideal functionality  $\mathcal{F}_{\Delta-\text{ROT}}$ ), allow the adversary to perform selective-failure attacks on a key R. Specifically, the adversary can choose a set L, and then the protocol aborts if  $R \notin L$ , or nothing happens otherwise. In other words,  $\mathcal{F}_{\Delta-\text{ROT}}$  allows the adversary to choose a predicate P and learns P(R), where the functionality aborts if P(R) = 0.

When applying  $\mathcal{F}_{\Delta-\text{ROT}}$  to design standard OT protocols via a generic transformation, a tweakable correlation robust (TCR) hash function will be used to protect the privacy of OT messages. If the key R suffers from selective-failure attacks, then the TCR hash function suffers from the selective-failure leakage on R. Besides, when applying  $\mathcal{F}_{\Delta-\text{ROT}}$  to construct constant-round secure multi-party computation (MPC) protocols (e.g., [25, 26, 14, 16, 32, 28, 10, 13]), the TCCR hash function will be used in the construction of distributed garbled circuits. In this case, the TCCR hash function also suffers from the selective-failure leakage on R.

Recently, Roy [23] incorporated the key-leakage oracle into the security definition of TCR, where the oracle takes an affine set L as input and aborts if  $R \in L$ . Roy proved that two instantiations satisfy the new security notion in the single-user setting, where one is proved in the random oracle model; the other is similar to the aforementioned  $\widehat{\mathsf{MMO}}^E$  construction but works in the ideal cipher model. The proven bounds are comparable with Guo et al. [11, Theorems 6 and 2], and are not tight. It is unknown whether the TCCR hash function (having the stronger security than TCR) has a tight security proof in the multi-user setting, when the adversary is allowed to have access to the general key-leakage oracle that returns P(R).

#### 1.1 Our contribution

We continue with the above line of work and extend [11,7,23] w.r.t. security definitions, feasibility results and applications.

Multi-user TCCR with key leakages. We augment the notion miTCCR of Guo et al. [11] with a key leaking oracle, and formalize the obtained security definition as multi-user TCCR with key leakages (muTCCRL). Concretely, our key leaking oracle takes a user index idx and a predicate P as input and answers if the idx-th user's key  $R_{idx}$  has  $P(R_{idx}) = 1$ . Compared with Roy [23], our notion muTCCRL allows for multiple users, multiple key leaking queries<sup>2</sup> and a much wider class of queried predicates.

Security of  $\widehat{\mathsf{MMO}}^E$ . We then investigate the aforementioned hash construction  $\widehat{\mathsf{MMO}}^E$  of Guo et al. with respect to our new security definition.

On the positive side, we prove security for  $\widehat{\mathsf{MMO}}^E$ . Assume that: (i) the *u* user keys  $R_1, ..., R_{\mathsf{idx}}$  are independently and uniformly sampled from an (oracleindependent) set  $\mathcal{R}$ , (ii) the adversary asks  $q_L$  queries to the key leaking oracle, and (iii) the adversary asks at most  $\mu$  construction queries per tweak (across multiple users), then security of  $\widehat{\mathsf{MMO}}^E$  is ensured up to roughly  $|\mathcal{R}|/(\mu q_L)$  ideal cipher queries and  $|\mathcal{R}|/(\mu q_L)$  construction queries. Our proof relies on a somewhat novel application of the H-coefficient method, which may be of some independent interest. On the practical side, NIST [19] has recently launched its standardization process of multi-party threshold cryptographic schemes. Our positive results thus provide promising building blocks to this end.

As mentioned before, practical applications could limit  $\mu$  to o(n) by using random initialization vectors (see our application below), and the  $\log_2 \mu$  bits security loss is rather small. On the other hand,  $q_L$  may be large in the multiuser setting (e.g., in our application below, it equals the number of corrupted receivers across the u OT extension instances), inducing a non-negligible security loss of  $\log_2 q_L$  bits. Unfortunately, we exhibit several attacks demonstrating tightness of this bound. By this, to have sufficient multi-user security in certain settings (e.g., see our application below), one may need larger security parameters.

Application to OT extension. Our new hashing result implies OT extension with non-trivial multi-user security. In detail, we present an OT extension protocol modified from the random-OT-to-standard-OT transformation of Guo et al. [12, Fig. 3]. Our protocol uses a random IV to control the number of collisions among tweak inputs of distinct hash calls, which borrows the idea of Guo et al. [11] on garbling. Compared with Chen and Tessaro [7, Fig. 3], our protocol does not invoke AXU hash functions. On the downside, we rely on our muTCCRL hash function  $\widehat{\mathsf{MMO}}^E$  using  $E: \{0,1\}^n \times \{0,1\}^n \to \{0,1\}^n$ , which is less efficient than Chen and Tessaro's two-call hash construction. Importantly, our protocol avoids the trivial  $\log_2 u$  bits multi-user security degradation: assume that the adversary corrupts C receivers, then u (independently initiated) instances of our new OT extension protocol are indistinguishable from u independent instances of the ideal standard-OT functionality, and security is of roughly  $k - \log_2 n - \log_2 C$  bits (k is the size of the secret shift). We refer to Sect. 5.2 for details. To our knowledge, this is the first non-trivial multi-user treatment of OT extensions.

<sup>&</sup>lt;sup>2</sup> Roy's security definition allows multiple key leaking queries, but from the results [23, Propositions 2.6, 2.7] and security proofs [22, Appendix A] it seems only a single key leaking query is allowed.

Organizations. We provide necessary preliminaries in Sect. 2. Then, in Sect. 3, we provide our multi-user TCCR definition; in Sect. 4, we discuss security of  $\widehat{\mathsf{MMO}}^E$ —both proven bounds and matching attacks. We then present our application to multi-user security of OT extension in Sect. 5. Finally, we conclude in Sect. 6.

## 2 Preliminary

For any integer  $j \in \{0, ..., m-1\}$ , denote by  $[j]_m$  the *m*-bit encoding of *j*. For any set or list S, we denote by |S| its size or "length", i.e., the number of elements in S.

We will rely on a slightly generalized version of [11, Lemma 1], which is stated as follows.

**Lemma 1** Fix integers n, q and  $u \leq q$ , a bijective function  $\gamma : [2^n - 1] \mapsto \{0, 1\}^n$  and a sequence of positive integers  $(q_1, \ldots, q_u)$  with  $\sum_{i=1}^u q_i = q$ . Consider the following experiment involving a set of  $2^n$  bins and q balls: for each  $i \in [u]$ ,  $q_i$  balls are placed in the bins of indices  $\gamma(1) \oplus IV_i, \gamma(2) \oplus IV_i, \ldots, \gamma(q_i) \oplus IV_i$ , where  $IV_i \stackrel{\$}{\leftarrow} \{0, 1\}^n$  is uniformly picked. If  $\mu^*$  is the random variable denoting the maximum number of balls in any bin, then

$$\Pr[\mu^* > \mu] \le \frac{q^{\mu+1}}{(\mu+1)! \cdot 2^{\mu n}}$$

Its proof, which essentially follows [11, Lemma 1], is given in Appendix A.

## 3 Multi-user TCCR with Key Leakages

Our definition of muTCCRL is an extension of Roy [22] to the multi-user setting. It may also be viewed as the miTCCR notion of Guo et al. [11] enhanced with a *key leaking oracle*. In detail, given a function  $H : \mathcal{W} \times \mathcal{T} \to \mathcal{W}$  (that depends on an ideal cipher E) and a vector of secrets  $\mathbf{R} = (R_1, ..., R_u)$ , define

$$\mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}, w, i, b) := H(w \oplus R_{\mathsf{idx}}, i) \oplus b \cdot R_{\mathsf{idx}}, \tag{1}$$

and define  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P), P \in \mathcal{P}$ , as the oracle that aborts the session of the idx-th user if and only if  $P(R_{\mathsf{idx}}) \neq 1$ . This means if the adversary keeps querying  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P)$  with  $P(R_{\mathsf{idx}}) = 1$  then nothing happens (by this, it gains information about  $R_{\mathsf{idx}}$  by knowing  $P(R_{\mathsf{idx}}) = 1$ ); once it queries  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P)$  with  $P(R_{\mathsf{idx}}) = 0$  then  $\mathcal{L}_{\mathbf{R}}$  never replies queries of the form (idx,  $\star$ ) and  $\mathcal{O}_{\mathbf{R}}^{\mathsf{muTCCRL}}$ never replies queries of the form (idx,  $\star, \star, \star$ ). (On the other hand, it is always required that  $P \in \mathcal{P}$ ).

Let  $\operatorname{Func}_{\{1,...,u\}\times\mathcal{W}\times\mathcal{T}\times\{0,1\},\mathcal{W}}$  denote the set of functions from  $\{1,...,u\}\times\mathcal{W}\times\mathcal{T}\times\{0,1\}$  to  $\mathcal{W}$ , and let  $\mathcal{E}(\mathcal{T},\mathcal{W})$  denote the set of blockciphers with keyspace  $\mathcal{T}$  and message space  $\mathcal{W}$ .

**Definition 1** (muTCCRL advantage) Given a function  $H^E : \mathcal{W} \times \mathcal{T} \to \mathcal{W}$ , a subset  $\mathcal{R} \subseteq \mathcal{W}$ , and a distinguisher  $\mathcal{D}$ , define

$$\begin{split} \mathbf{Adv}_{H,\mathcal{R},\mathcal{P},u,\mu}^{\mathrm{muTCCRL}}(\mathcal{D}) &:= \left| \Pr_{\substack{E \overset{\$}{\leftarrow} \mathcal{E}(\mathcal{T},\mathcal{W}), \mathbf{R} \overset{\$}{\leftarrow} (\mathcal{R})^{u}}} \left[ \mathcal{D}^{E,\mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}},\mathcal{L}_{\mathbf{R}}} = 1 \right] \right. \\ &- \Pr_{\substack{f \leftarrow \mathsf{Func}_{\{1,\ldots,u\} \times \mathcal{W} \times \mathcal{T} \times \{0,1\}, \mathcal{W}, E \overset{\$}{\leftarrow} \mathcal{E}(\mathcal{T},\mathcal{W}), \mathbf{R} \overset{\$}{\leftarrow} (\mathcal{R})^{u}}} \left[ \mathcal{D}^{E,f,\mathcal{L}_{\mathbf{R}}} = 1 \right] \right|, \end{split}$$

where both probabilities are also over choice of E and we require that

- (i)  $\mathcal{D}$  never queries both (idx, w, i, 0) and (idx, w, i, 1) to its second oracle (for any idx, w, i).
- (ii) For all  $i \in \mathcal{T}$ , the number of queries (across all oracles) of the form  $(\star, \star, i, \star)$  is at most  $\mu$ .
- (iii) Every query (idx, P) of  $\mathcal{D}$  to its third oracle  $\mathcal{L}_{\mathbf{R}}$  has  $P \in \mathcal{P}$ .

For convenience, define

$$\mathbf{Adv}_{H,\mathcal{R},\mathcal{P},u,\mu}^{\mathrm{muTCCRL}}(q_E,q_C,q_L) := \max_{\mathcal{D}} \left\{ \mathbf{Adv}_{H,\mathcal{R},\mathcal{P},u,\mu}^{\mathrm{muTCCRL}}(\mathcal{D}) \right\}$$

where the maximum is taken over all distinguishers  $\mathcal{D}$  making at most  $q_E$  queries to E, at most  $q_C$  queries to  $\mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}/f$  and at most  $q_L$  queries to  $\mathcal{L}_{\mathbf{R}}$ .

We recover the definition of Guo et al. [11] if we remove the key leaking oracle  $\mathcal{L}_{\mathbf{R}}$ . Note that we follow Guo et al. [11] and explicitly allow the concrete security bound to depend on the maximum number of times  $\mu$  an attacker repeats any particular tweak.

We remark that Chen and Tessaro [7] also discussed the issue when the key set  $\mathcal{R}$  depends on the ideal cipher E. In our current formalism, the cipher E is uniformly sampled *after*  $\mathcal{R}$  is fixed and given. In this manner, the primitive-dependency is avoided (we thank Chen and Tessaro for pointing the two issues).

# 4 Multi-user TCCRL Security of $\widehat{\mathsf{MMO}}^E$

This section proves muTCCRL security for the hash

$$\widehat{\mathsf{MMO}}^E(x,i) := E(i,\sigma(x)) \oplus \sigma(x)$$

where  $E: \{0,1\}^n \times \{0,1\}^n \to \{0,1\}^n$  is a blockcipher and  $\sigma$  is a linear orthomorphism. We only consider the case of  $\mathcal{D}$  using *oracle-free* predicates for its key leaking oracle queries. Namely, for every query  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P)$ , the predicate evaluation  $P(R_{\mathsf{idx}})$  does not query the ideal cipher E. Formally, let  $\mathcal{P}_{\mathsf{free}}$  be the set of all such oracle-free predicates. For clarity, we will also sketch the influences of oracle-freeness in footnote 3. **Theorem 1** If  $\sigma$  is a linear orthomorphism and E is modeled as an ideal cipher, then the muTCCRL advantage of  $\widehat{\mathsf{MMO}}^E$  has upper bound

$$\mathbf{Adv}_{H,\mathcal{R},\mathcal{P},u,\mu}^{\mathrm{muTCCRL}}(q_E, q_C, q_L) \le \frac{2\mu q_E(q_L+1)}{|\mathcal{R}|} + \frac{(\mu-1) \cdot q_C(q_L+1)}{|\mathcal{R}|}.$$
 (2)

Below we first elaborate on the concrete bounds in Sect. 4.1. We then give the main proof flow of Theorem 1 in Sect. 4.2, and the proof of a core lemma is deferred to Sect. 4.3. We conclude this section with several matching attacks in Sect. 4.4.

#### 4.1 Bounds in concrete scenarios

As demonstrated by Guo et al. [11, Theorem 3] (also see Theorem 2 of this paper),  $\mu$  can be limited to O(n) or even O(1) by using somewhat random tweaks in the protocol. By this, Eq. (2) seems to indicate security up to  $q_E q_L \ll |\mathcal{R}|$  and  $q_C q_L \ll |\mathcal{R}|$ , which is much inferior to Guo et al. [11, Theorem 2]. Unfortunately, this is tight, and we refer to the attacks in Sect. 4.4.1 for more details.

On the other hand, in concrete scenarios,  $q_L$  may be rather limited, which entails much better concrete security. For example, in an execution of the OT extension protocol, the number of key leaking oracle queries  $q_L$  is equal to the number C of iterations in OT extension. The number of iterations depends on the concrete applications and memory, but we often have C = O(1) in general. In this case, concrete security is ensured up to  $|\mathcal{R}|/(\mu C) \approx |\mathcal{R}|$  ideal cipher queries and  $|\mathcal{R}|/(\mu C) \approx |\mathcal{R}|$  construction queries. We refer to Theorem 2 for more details.

#### 4.2 Proof of Theorem 1

#### 4.2.1 Preparations

Our proof uses the H-coefficient technique [21,5]. We provide a brief review, adapted from [12]. Fix a deterministic distinguisher  $\mathcal{D}$  that is given access to an ideal cipher  $E : \{0,1\}^n \times \{0,1\}^n \to \{0,1\}^n$ , a key leaking oracle  $\mathcal{L}_{\mathbf{R}}$ , as well as an additional construction oracle  $\mathcal{O}$ : in the real world,  $\mathcal{O}$  is the oracle defined in Eq. (1); in the ideal world,  $\mathcal{O}$  is the function uniformly chosen from  $\mathsf{Func}_{\{1,\ldots,u\}\times\mathcal{W}\times\mathcal{T}\times\{0,1\},\mathcal{W}}$ . We are interested in bounding the maximum difference between the probabilities that  $\mathcal{D}$  outputs 1 in the real world vs. the ideal world, where the maximum is taken over all  $\mathcal{D}$  making  $q_E$  queries to E,  $q_C$  queries to the construction oracle and  $q_L$  queries to  $\mathcal{L}_{\mathbf{R}}$ .

For any predicate P, let  $\mathcal{R}(P) \subseteq \mathcal{R}$  be the set of keys that fulfill P, i.e.,

$$\mathcal{R}(P) := \{ R \in \mathcal{R} : P(R) = 1 \},\tag{3}$$

To simplify notations, we normalize the distinguisher  $\mathcal{D}$  such that it never issues "redundant" queries to  $\mathcal{L}_{\mathbf{R}}$ . In detail, for any user index  $\mathsf{idx} \in \{1, ..., u\}$ and any sequence of  $\mathcal{L}_{\mathbf{R}}$  queries  $(\mathsf{idx}, P_1)$ ,  $(\mathsf{idx}, P_2)$ , ...,  $(\mathsf{idx}, P_{j-1})$ ,  $(\mathsf{idx}, P_j)$ , it holds

$$\mathcal{R}(P_2) \cap (\mathcal{R} \setminus \mathcal{R}(P_1)) = \emptyset,$$
  
$$\mathcal{R}(P_3) \cap (\mathcal{R}(P_1) \setminus \mathcal{R}(P_2)) = \emptyset,$$
  
...,  
$$\mathcal{R}(P_j) \cap (\mathcal{R}(P_{j-2}) \setminus \mathcal{R}(P_{j-1})) = \emptyset,$$

This is reasonable in the following sense: since earlier queries  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P_{j-2})$  and  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P_{j-1})$  both return 1, one knows  $R_{\mathsf{idx}}$  cannot be in  $(\mathcal{R}(P_{j-2})\setminus\mathcal{R}(P_{j-1}))$ , and it is "redundant" to ask  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, \cdot)$  for  $\mathcal{R}(P_j) \cap (\mathcal{R}(P_{j-2})\setminus\mathcal{R}(P_{j-1})) \neq \emptyset$ . Meanwhile, since we don't limit the computation power, for any distinguisher  $\mathcal{D}$  it is easy to construct a "normalized" distinguisher  $\overline{\mathcal{D}}$  satisfying the above restrictions.

#### 4.2.2 H-coefficient method

A raw transcript of D's interaction is an ordered list

$$Q = ((\mathsf{T}_1, \mathsf{Q}_1, \mathsf{A}_1), (\mathsf{T}_2, \mathsf{Q}_2, \mathsf{A}_2), ...),$$
(4)

where the *i*-th triple  $(T_i, Q_i, A_i)$  means:

- When  $\mathsf{T}_i = E$ , it has  $\mathsf{Q}_i = (k, x)$  and  $\mathsf{A}_i = y \in \{0, 1\}^n$  which indicate that the *i*-th query is a forward query to the ideal cipher  $E(k, x) \to y$ ;
- When  $\mathsf{T}_i = E^{-1}$ , it has  $\mathsf{Q}_i = (k, y)$  and  $\mathsf{A}_i = x \in \{0, 1\}^n$  which indicate that the *i*-th query is a backward query to the ideal cipher  $E^{-1}(k, y) \to x$ ;
- When  $\mathsf{T}_i = \mathcal{O}$ , it has  $\mathsf{Q}_i = (\mathsf{idx}, w, i, b)$  and  $\mathsf{A}_i = z \in \{0, 1\}^n$  which indicate that the *i*-th query is a construction query  $\mathcal{O}(\mathsf{idx}, w, i, b) \to z$ ;
- When  $\mathsf{T}_i = \mathcal{L}$ , it has  $\mathsf{Q}_i = (\mathsf{idx}, P)$  and  $\mathsf{A}_i = r \in \{0, 1\}$  which indicate that the *i*-th query is a key leaking query  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P) \to r$ . Since  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P)$ causes abort when  $P(R_{\mathsf{idx}}) = 0$ , if r = 0 then subsequent queries can only be ideal cipher queries. For every  $\mathsf{idx} \in \{1, ..., u\}$ , let

$$(\mathcal{L}, (\mathsf{idx}, P_{\mathsf{idx},1}), r_{\mathsf{idx},1}), \dots, (\mathcal{L}, (\mathsf{idx}, P_{\mathsf{idx}, t_{\mathsf{idx}}-1}), r_{\mathsf{idx}, t_{\mathsf{idx}}-1}), (\mathcal{L}, (\mathsf{idx}, P_{\mathsf{idx}, t_{\mathsf{idx}}}), r_{\mathsf{idx}, t_{\mathsf{idx}}})$$

be the ordered list of all key leaking queries to  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, \cdot)$  (the idx-th user) in  $\mathcal{Q}$ . It necessarily holds  $r_{\mathsf{idx},1} = \ldots = r_{\mathsf{idx},t_{\mathsf{idx}}-1} = 1$ : otherwise, the idx-th user's "session" should have been aborted and  $\mathcal{D}$  should not have been able to query  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P_{t_{\mathsf{idx}}})$ .

A raw transcript Q is *attainable* for some fixed D if there exist some ideal world oracles such that the interaction of D with those oracles would lead to transcript Q. Denote by T the set of such attainable raw transcripts.

Our definition of transcripts deviate from the common forms (e.g., [5,4]): we consider *ordered* list, and the query types matter as well. As will become clear, our arguments rely on these ingredients. On the other hand, the fundamental ideas and lemmas of the H-coefficient method still hold for our formalism.

We follow previous works [5] and reveal the keys to  $\mathcal{D}$  at the end of the interactions. For this, let

$$\mathcal{L}_{\mathbf{R}} \vdash \mathcal{Q}$$

denote the event that the key leaking oracle  $\mathcal{L}_{\mathbf{R}}$  gives responses that are consistent with all leaking query records in  $\mathcal{Q}$ , i.e.,  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, P) = r$  for all  $(\mathcal{L}, (\mathsf{idx}, P), r) \in \mathcal{Q}$ . Then, the key vector  $\mathbf{R}$  is appended to the transcript to facilitate the analysis: in the real world, these are the actual keys used by the oracles  $\mathcal{O}_{\mathbf{R}}^{\mathsf{muTCCRL}}$  and  $\mathcal{L}_{\mathbf{R}}$ , whereas in the ideal world it's a "dummy" key vector uniformly sampled from the set

$$\mathcal{R}(\mathcal{Q}) := \left\{ \mathbf{R}^* \in (\mathcal{R})^u : \mathcal{L}_{\mathbf{R}^*} \vdash \mathcal{Q} \right\},\tag{5}$$

This means they may *not* be the same as the keys actually used by  $\mathcal{L}_{\mathbf{R}}$  in the ideal world. Define  $\mathcal{Q}_x := (\mathcal{Q}, \mathbf{R})$  as the final adversarial transcript. A transcript  $\mathcal{Q}_x = (\mathcal{Q}, \mathbf{R})$  is *attainable* for some fixed  $\mathcal{D}$ , if  $\mathcal{Q} \in \mathcal{T}$  and  $\mathbf{R} \in \mathcal{R}(\mathcal{Q})$ , i.e., **R** can be sampled as the "dummy" key vector. Denote by  $\mathcal{T}_x$  the set of such attainable (final) transcripts.

Fix a deterministic distinguisher  $\mathcal{D}$  that interacts with either the real world oracles  $(E, \mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}, \mathcal{L}_{\mathbf{R}})$  or the ideal world oracles  $(E, f, \mathcal{L}_{\mathbf{R}})$ . Let  $T_{\mathrm{re}}$ , resp.  $T_{\mathrm{id}}$ , be the random variable corresponding to D's transcript in the real, resp. ideal, world. The H-coefficient technique involves defining a partition of  $\mathcal{T}$  into a "bad" set  $\mathcal{T}_{\mathsf{bad}}$  and a "good" set  $\mathcal{T}_{\mathsf{good}} = \mathcal{T} \setminus \mathcal{T}_{\mathsf{bad}}$ , and then showing that

$$\Pr[T_{id} \in \mathcal{T}_{bad}] \leq \varepsilon_1$$

and

$$\forall \mathcal{Q}_x \in \mathcal{T}_{\mathsf{good}} : \frac{\Pr[T_{\mathrm{re}} = \mathcal{Q}_x]}{\Pr[T_{\mathrm{id}} = \mathcal{Q}_x]} \ge 1 - \varepsilon_2.$$

The distinguishing advantage of  $\mathcal{D}$  is then at most  $\varepsilon_1 + \varepsilon_2$ .

Ideal world probability. One of the key insights of the H-coefficient technique is that the value of  $\Pr[T_{re} = Q_x]/\Pr[T_{id} = Q_x]$  is equal to the ratio between the probability that the real-world oracles are consistent with  $Q_x$  and the probability that the ideal-world oracles are consistent with  $Q_x$ . To this end, for each transcript  $Q_x = (Q, \mathbf{R})$  and each  $k \in \{0, 1\}^n$ , define Q[E, k] as

$$\mathcal{Q}[E,k] := \{(k,x,y) : (E,(k,x),y) \in \mathcal{Q} \text{ or } (E^{-1},(k,y),x) \in \mathcal{Q}\}, \quad (6)$$

and define  $\mathcal{Q}[E] := \bigcup_{k \in \{0,1\}^n} \mathcal{Q}[E,k]$  as their union. Let  $E \vdash \mathcal{Q}$  denote the event that block cipher E is consistent with all ideal cipher queries and answers in  $\mathcal{Q}$ , i.e., that E(k, x) = y as long as  $(E, (k, x), y) \in \mathcal{Q}$  or  $(E^{-1}, (k, y), x) \in \mathcal{Q}$ .

Then, the probability to have  $E \vdash Q$  for an ideal cipher (with *n*-bit blocks and *n*-bit keys) is

$$\left(\prod_{k\in\{0,1\}^n} (2^n)_{|\mathcal{Q}[E,k]|}\right)^{-1}$$

where for integers  $1 \leq b \leq a$ , we set  $(a)_b = a \cdot (a-1) \cdots (a-b+1)$ , with  $(a)_0 = 1$  by convention.

Define  $\mathcal{Q}[\mathcal{O}]$  as the set of construction queries in  $\mathcal{Q}$ , i.e.,

$$\mathcal{Q}[\mathcal{O}] := \left\{ (\mathsf{idx}, w, i, b, z) : (\mathcal{O}, (\mathsf{idx}, w, i, b), z) \in \mathcal{Q} \right\}.$$
(7)

Similarly, for a function  $f \in \mathsf{Func}_{\{1,...,u\} \times W \times \mathcal{T} \times \{0,1\}, W}$ , let  $f \vdash \mathcal{Q}$  denote the event that f is consistent with all construction queries and answers in  $\mathcal{Q}$ , i.e., that  $f(\mathsf{idx}, w, i, b) = z$  for all  $(\mathcal{O}, (\mathsf{idx}, w, i, b), z) \in \mathcal{Q}$ . Then, the probability to have  $f \vdash \mathcal{Q}$  for a random function  $f \stackrel{\leq}{\leftarrow} \mathsf{Func}_{\{1,...,u\} \times W \times \mathcal{T} \times \{0,1\}, W}$  is

 $\frac{1}{2^{|\mathcal{Q}[\mathcal{O}]|n}}.$ 

For each  $\mathsf{idx} \in \{1, ..., u\}$ , let  $(\mathcal{L}, (\mathsf{idx}, P_{\mathsf{idx},1}), r_{\mathsf{idx},1}), \ldots, (\mathcal{L}, (\mathsf{idx}, P_{t_{\mathsf{idx}}}), r_{\mathsf{idx},t_{\mathsf{idx}}})$ be the key leaking query records of the  $\mathsf{idx}$ -th user in  $\mathcal{Q}$ , where  $t \leq q_L$ . Define

$$\mathcal{R}(\mathcal{Q}, \mathsf{idx}) := \left\{ R \in \mathcal{R} : P_{\mathsf{idx}, 1}(R) = r_{\mathsf{idx}, 1} \wedge \dots \wedge P_{\mathsf{idx}, t_{\mathsf{idx}}}(R) = r_{\mathsf{idx}, t_{\mathsf{idx}}} \right\}$$
(8)

as the key set compatible with  $(\mathcal{L}, (\mathsf{idx}, P_{\mathsf{idx},1}), r_{\mathsf{idx},1}), \ldots, (\mathcal{L}, (\mathsf{idx}, P_{t_{\mathsf{idx}}}), r_{\mathsf{idx},t_{\mathsf{idx}}})$ . This means  $\mathcal{R}(\mathcal{Q}) = \mathcal{R}(\mathcal{Q}, 1) \times \mathcal{R}(\mathcal{Q}, 2) \times \ldots \times \mathcal{R}(\mathcal{Q}, u)$ .

Then, by our assumption of distinguisher normalization and by Eq. (8), it can be seen

$$|\mathcal{R}(\mathcal{Q}, \mathsf{idx})| = \begin{cases} |\mathcal{R}(P_{\mathsf{idx}, t_{\mathsf{idx}}})| & \text{if } r_{\mathsf{idx}, t_{\mathsf{idx}}} = 1\\ |\mathcal{R}(P_{\mathsf{idx}, t_{\mathsf{idx}} - 1})| - |\mathcal{R}(P_{\mathsf{idx}, t_{\mathsf{idx}}})| & \text{if } r_{\mathsf{idx}, t_{\mathsf{idx}}} = 0 \end{cases}$$

Thus,

$$\Pr[\mathcal{L}_{\mathbf{R}} \vdash \mathcal{Q}] = \Pr[(R_1, ..., R_u) \stackrel{\text{\tiny{\&}}}{\leftarrow} (\mathcal{R})^u : R_1 \in \mathcal{R}(\mathcal{Q}, 1) \land ... \land R_u \in \mathcal{R}(\mathcal{Q}, u)]$$
$$= \prod_{\mathsf{idx}=1}^u \frac{|\mathcal{R}(\mathcal{Q}, \mathsf{idx})|}{|\mathcal{R}|}.$$

For simplicity, write

$$(E, f, \mathbf{R}) \vdash \mathcal{Q}$$

for the event  $E \vdash \mathcal{Q} \land f \vdash \mathcal{Q} \land \mathcal{L}_{\mathbf{R}} \vdash \mathcal{Q}$ . The key insight is that  $T_{id} = \mathcal{Q}$ , the event that the ideal world execution gives rise to the raw transcript  $\mathcal{Q}$ , is equivalent with the event  $(E, f, \mathbf{R}) \vdash \mathcal{Q}$ .

Finally, in the ideal world, the probability that the "dummy" key vector sampled at the end equals a given vector **R** is  $\prod_{idx=1}^{u} \frac{1}{|\mathcal{R}(\mathcal{Q}, idx)|}$ .<sup>3</sup> Therefore, for

<sup>&</sup>lt;sup>3</sup> If the predicates can be oracle-dependent, then it seems we need to append the ideal cipher query records of the predicates to Q as well: otherwise, it is non-trivial to define  $\mathcal{R}(Q, \mathsf{idx})$ . This may induce an "unreal" loss in the derived security bounds.

any attainable (final) transcript  $Q_x = (Q, \mathbf{R})$ , the probability that the ideal world is consistent with  $Q_x$  is computed by

$$\frac{1}{\prod_{k\in\{0,1\}^n} (2^n)_{|\mathcal{Q}[E,k]|}} \times \frac{1}{2^{nq_C}} \times \left(\prod_{\mathsf{idx}=1}^u \frac{|\mathcal{R}(\mathcal{Q},\mathsf{idx})|}{|\mathcal{R}|}\right) \times \left(\prod_{\mathsf{idx}=1}^u \frac{1}{|\mathcal{R}(\mathcal{Q},\mathsf{idx})|}\right) \\
= \frac{1}{\prod_{k\in\{0,1\}^n} (2^n)_{|\mathcal{Q}[E,k]|} \cdot 2^{nq_C} \cdot |\mathcal{R}|^u}.$$
(9)

(We assume  $|\mathcal{Q}[\mathcal{O}]| = q_C$ , i.e., D always makes exactly  $q_C$  queries to its construction oracles.) Bounding the distinguishing advantage of  $\mathcal{D}$  thus reduces to bounding the probability that the real world is consistent with  $\mathcal{Q}_x \in \mathcal{T}_{good}$ .

Real world probability. Since, in the real world, the behavior of the second oracle is completely determined by E and  $\mathbf{R}$ , we can also write  $(E, \mathbf{R}) \vdash \mathcal{Q}[\mathcal{O}]$  to denote the event that cipher E and keys  $\mathbf{R}$  are consistent with the construction queries/answers in  $\mathcal{Q}$ . For a (good) transcript  $\mathcal{Q}$ , the probability that the real world is consistent with  $\mathcal{Q}$  is exactly

$$\begin{aligned} &\Pr[E \vdash \mathcal{Q}] \times \Pr[\mathcal{L}_{\mathbf{R}^*} \vdash \mathcal{Q}] \times \Pr[\mathbf{R}^* = \mathbf{R} \mid \mathcal{L}_{\mathbf{R}^*} \vdash \mathcal{Q}] \\ & \times \Pr[(E, \mathbf{R}^*) \vdash \mathcal{Q}[\mathcal{O}] \mid E \vdash \mathcal{Q} \land \mathbf{R}^* = \mathbf{R}] \end{aligned} \\ &= \Pr[E \vdash \mathcal{Q}] \times \Pr[\mathbf{R}^* \xleftarrow{\$} (\mathcal{R})^u : \mathbf{R}^* = \mathbf{R}] \times \Pr[(E, \mathbf{R}^*) \vdash \mathcal{Q}[\mathcal{O}] \mid E \vdash \mathcal{Q} \land \mathbf{R}^* = \mathbf{R}]. \end{aligned}$$

We have  $\Pr[E \vdash Q] = 1/\prod_{k \in \{0,1\}^n} (2^n)_{|Q[E,k]|}$  exactly as before. The crux of the proof thus reduces to showing a bound on  $\Pr[(E, \mathbf{R}^*) \vdash Q[\mathcal{O}] \mid E \vdash Q \land \mathbf{R}^* = \mathbf{R}]$ . Note that we can equivalently express it as  $\Pr[\forall (\mathcal{O}, (\mathsf{idx}, w, i, b), z) \in Q : \mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}, w, i, b) = z \mid E \vdash Q]$ .

#### 4.2.3 Bad transcripts

We say a transcript  $(\mathcal{Q}, \mathbf{R})$  is *bad* if:

- (B-1) There is a query record  $(\mathcal{O}, (\mathsf{idx}, w, i, b), z) \in \mathcal{Q}$  and a record of the form  $(i, \sigma(R_{\mathsf{idx}} \oplus w), \star)$  or of the form  $(i, \star, \sigma(R_{\mathsf{idx}} \oplus w) \oplus b \cdot R_{\mathsf{idx}} \oplus z)$  in  $\mathcal{Q}[E]$ .
- (B-2) There are distinct  $(\mathcal{O}, (\mathsf{idx}, w, i, b), z)$  and  $(\mathcal{O}, (\mathsf{idx}', w', i, b'), z') \in \mathcal{Q}$ using the same "tweak" *i* such that  $\sigma(R_{\mathsf{idx}} \oplus w) = \sigma(R_{\mathsf{idx}'} \oplus w')$ .
- (B-3) There are distinct  $(\mathcal{O}, (\mathsf{idx}, w, i, b), z)$  and  $(\mathcal{O}, (\mathsf{idx}', w', i, b'), z') \in \mathcal{Q}$ using the same "tweak" *i* such that  $\sigma(R_{\mathsf{idx}} \oplus w) \oplus b \cdot R_{\mathsf{idx}} \oplus z = \sigma(R_{\mathsf{idx}'} \oplus w') \oplus b' \cdot R_{\mathsf{idx}'} \oplus z'$ .

We bound the probabilities of the above conditions regarding the ideal world probability. First, (B-1) and (B-2) are fulfilled only if the "dummy" key vector **R** (sampled at the end) falls into a certain set of "bad keys". For this, for any  $(\mathcal{O}, (\operatorname{idx}, w, i, b), z) \in \mathcal{Q}$ , define

$$\mathsf{Bad}\mathsf{K}_{1}^{+}(\mathsf{idx}, w, i, b, z) := \left\{ \mathbf{R} \in (\mathcal{R})^{u} : (i, \sigma(R_{\mathsf{idx}} \oplus w), \star) \in \mathcal{Q}[E] \right\}$$
$$\mathsf{Bad}\mathsf{K}_{1}^{-}(\mathsf{idx}, w, i, b, z) := \left\{ \mathbf{R} \in (\mathcal{R})^{u} : (i, \star, \sigma(R_{\mathsf{idx}} \oplus w) \oplus bR_{\mathsf{idx}} \oplus z) \in \mathcal{Q}[E] \right\}.$$
(10)

For each record  $(i, x, y) \in \mathcal{Q}[E, i]$ , the number of  $R_{\mathsf{idx}}$  such that  $\sigma(R_{\mathsf{idx}} \oplus w) = x$  is exactly one, since  $\sigma$  is a permutation. This means

$$|\mathsf{BadK}_1^+(\mathsf{idx}, w, i, b, z)| \le |\mathcal{Q}[E, i]| imes |\mathcal{R}|^{u-1}$$

On the other hand, the condition  $(i, \star, \sigma(R_{\mathsf{idx}} \oplus w) \oplus bR_{\mathsf{idx}} \oplus z) \in \mathcal{Q}[E]$  is equivalent with  $(i, \star, \sigma(R_{\mathsf{idx}}) \oplus \sigma(w) \oplus bR_{\mathsf{idx}} \oplus z) \in \mathcal{Q}[E]$  by linearity of  $\sigma$ . Now, note that:

- When b = 0, the number of  $R_{idx}$  such that  $(i, \sigma(R_{idx} \oplus w), \star) \in \mathcal{Q}[E]$  is at most  $|\mathcal{Q}[E, i]|$ , since  $\sigma$  is a permutation;
- When b = 1, the number of  $R_{\mathsf{idx}}$  such that  $(i, \star, \sigma(R_{\mathsf{idx}} \oplus w) \oplus bR_{\mathsf{idx}} \oplus z) \in \mathcal{Q}[E]$  is at most  $|\mathcal{Q}[E, i]|$  as well, since  $\sigma$  is an orthomorphism.

Therefore, it always holds  $\left|\mathsf{BadK}_1^-(\mathsf{idx}, w, i, b, z)\right| \le |\mathcal{Q}[E, i]| \times |\mathcal{R}|^{u-1}$ . Define

$$\mathsf{Bad}\mathsf{K}_1(\mathcal{Q}) := \bigcup_{(\mathcal{O}, (\mathsf{idx}, w, i, b), z) \in \mathcal{Q}} \Big(\mathsf{Bad}\mathsf{K}_1^+(\mathsf{idx}, w, i, b, z) \cup \mathsf{Bad}\mathsf{K}_1^-(\mathsf{idx}, w, i, b, z)\Big),$$

it then holds

$$\begin{split} \left|\mathsf{BadK}_1(\mathcal{Q})\right| &\leq \sum_{\substack{(\mathsf{idx}, w, i, b, z) \in \mathcal{Q}_{\mathcal{O}} \\ i \in \{0, 1\}^n}} 2 \cdot \left|\mathcal{Q}[E, i]\right| \times |\mathcal{R}|^{u-1} \\ &= \sum_{i \in \{0, 1\}^n} \sum_{\substack{(\mathsf{idx}, w, i, b, z) \in \mathcal{Q}_{\mathcal{O}} \\ \leq \mu}} 2 \cdot \left|\mathcal{Q}[E, i]\right| \times |\mathcal{R}|^{u-1} \\ &\leq \mu \cdot \sum_{i \in \{0, 1\}^n} 2 \cdot \left|\mathcal{Q}[E, i]\right| \times |\mathcal{R}|^{u-1} = 2\mu q_E |\mathcal{R}|^{u-1}. \end{split}$$

We follow similar ideas for (B-2). In detail, for each pair of distinct records  $(\mathcal{O}, (\mathsf{idx}, w, i, b), z), (\mathcal{O}, (\mathsf{idx}', w', i, b'), z') \in \mathcal{Q}$  sharing the same "tweak" *i*, define

$$\mathsf{BadK}_2\big((\mathsf{idx}, w, i, b, z), (\mathsf{idx}', w', i, b', z')\big)$$
$$:= \big\{\mathbf{R} \in (\mathcal{R})^u : \sigma(R_{\mathsf{idx}} \oplus w) = \sigma(R_{\mathsf{idx}'} \oplus w')\big\}.$$

We distinguish two cases.

Case 1:  $idx \neq idx'$ . Given a choice of  $(R_1, ..., R_{idx-1}, R_{idx-1}, ..., R_u)$ , the number of which is  $|\mathcal{R}|^{u-1}$ , the number of choices of  $R_{idx}$  satisfying either  $\sigma(R_{idx} \oplus w) = \sigma(R_{idx'} \oplus w')$  is exactly 1. Therefore,

$$\left|\mathsf{BadK}_2((\mathsf{idx}, w, i, b, z), (\mathsf{idx}', w', i, b', z'))\right| = |\mathcal{R}|^{u-1}.$$

Case 2: idx = idx'. In this case, the condition  $\sigma(R_{idx} \oplus w) = \sigma(R_{idx'} \oplus w')$  is equivalent with w = w', which is not possible. Therefore,

$$\mathsf{BadK}_2\big((\mathsf{idx},w,i,b,z),(\mathsf{idx}',w',i,b',z')\big)\big|=0$$

Summary. Define

# $\mathsf{BadK}_2(\mathcal{Q})$

$$:= \bigcup_{(\mathcal{O}, (\mathsf{idx}, w, i, b), z), (\mathcal{O}, (\mathsf{idx}', w', i, b'), z') \in \mathcal{Q}} \mathsf{BadK}_2\big((\mathsf{idx}, w, i, b, z), (\mathsf{idx}', w', i, b', z')\big).$$

If we let  $C_i \leq \mu$  denote the number of queries in  $\mathcal{Q}[\mathcal{O}]$  using tweak *i*, then

$$\begin{split} \left|\mathsf{BadK}_2(\mathcal{Q})\right| &\leq \sum_{(\mathcal{O},(\mathsf{idx},w,i,b),z),(\mathcal{O},(\mathsf{idx}',w',i,b'),z')\in\mathcal{Q}} |\mathcal{R}|^{u-1} \\ &\leq \sum_{i\in\{0,1\}^n} \binom{C_i}{2} |\mathcal{R}|^{u-1} \\ &\leq (\mu-1)\sum_{i\in\{0,1\}^n} C_i |\mathcal{R}|^{u-1} \leq \frac{(\mu-1)\cdot q_C\cdot |\mathcal{R}|^{u-1}}{2}. \end{split}$$

To simplify notations, define a constant

$$CON := \left(2\mu q_E + \frac{(\mu - 1) \cdot q_C}{2}\right) |\mathcal{R}|^{u-1}.$$
 (11)

Since the key vector  $\mathbf{R}$  in  $\mathcal{Q}_x = (\mathcal{Q}, \mathbf{R})$  is sampled from  $\mathcal{R}(\mathcal{Q})$  at the end, it holds

$$\Pr\big[\mathbf{R} \in \mathsf{BadK}_i(\mathcal{Q}) \mid T_{\mathrm{id}} = \mathcal{Q}\big] \le \min\left\{\frac{\left|\mathsf{BadK}_i(\mathcal{Q})\right|}{\left|\mathcal{R}(\mathcal{Q})\right|}, 1\right\} \le \frac{\left|\mathsf{BadK}_i(\mathcal{Q})\right|}{\left|\mathcal{R}(\mathcal{Q})\right|}$$

for i = 1, 2. Since (B-1)  $\vee$  (B-2) is fulfilled if and only if  $\mathbf{R} \in (\mathsf{BadK}_1(\mathcal{Q}) \cup \mathsf{BadK}_2(\mathcal{Q}))$ , we have

$$\Pr[(B-1) \lor (B-2)] \leq \sum_{\mathcal{Q} \in \mathcal{T}} \left( \Pr[T_{id} = \mathcal{Q}] \times \Pr[\mathbf{R} \in (\mathsf{BadK}_1(\mathcal{Q}) \cup \mathsf{BadK}_2(\mathcal{Q})) \mid T_{id} = \mathcal{Q}] \right) \\ \leq \sum_{\mathcal{Q} \in \mathcal{T}} \left( \Pr[T_{id} = \mathcal{Q}] \times \frac{|\mathsf{BadK}_1(\mathcal{Q})| + |\mathsf{BadK}_2(\mathcal{Q})|}{|\mathcal{R}(\mathcal{Q})|} \right) \\ \leq \sum_{\mathcal{Q} \in \mathcal{T}} \left( \Pr[(E, f, \mathbf{R}) \vdash \mathcal{Q}] \times \frac{CON}{|\mathcal{R}(\mathcal{Q})|} \right).$$
(12)

We finally consider (B-3). For fixed  $i \in \{0,1\}^n$ , consider a pair of distinct queries (idx, w, i, b, z), (idx', w', i, b', z')  $\in \mathcal{Q}_{\mathcal{O}}$ . With  $b'' = b \oplus b'$ ,

$$\begin{aligned} \Pr \big[ \sigma(R_{\mathsf{idx}} \oplus w) \oplus bR_{\mathsf{idx}} \oplus z &= \sigma(R_{\mathsf{idx}'} \oplus w') \oplus b'R_{\mathsf{idx}'} \oplus z' \big] \\ &= \Pr \big[ \sigma(w) \oplus z &= \sigma(w') \oplus z' \oplus b''R_{\mathsf{idx}} \big] = \frac{1}{2^n}, \end{aligned}$$

using the fact that  $z, z' \in \{0, 1\}^n$  are uniform and independent. If we let  $C_i \leq \mu$  denote the number of queries in  $\mathcal{Q}[\mathcal{O}]$  using tweak *i*, then

$$\Pr\left[(\text{B-3})\right] \le \sum_{i \in \{0,1\}^n} \binom{C_i}{2} \cdot \frac{1}{2^n} \le (\mu - 1) \sum_{i \in \{0,1\}^n} \frac{C_i}{2^{n+1}} \le \frac{(\mu - 1) \cdot q_C}{2^{n+1}}.$$
 (13)

Gathering Eqs. (12) and (13) yields

$$\Pr[T_{id} \in \mathcal{T}_{bad}] \leq \Pr[(B-1) \lor (B-2)] + \Pr[(B-3)]$$
$$\leq \frac{(\mu-1) \cdot q_C}{2^{n+1}} + \underbrace{\sum_{\mathcal{Q} \in \mathcal{T}} \left(\Pr[(E, f, \mathbf{R}) \vdash \mathcal{Q}] \times \frac{CON}{|\mathcal{R}(\mathcal{Q})|}\right)}_{S}.$$

Below in Sect. 4.3, we prove

$$S \le \frac{(q_L + 1)CON}{\left|\mathcal{R}\right|^u},\tag{14}$$

which is the most technical step. Therefore,

$$\Pr[T_{id} \in \mathcal{T}_{\mathsf{bad}}] \leq \frac{(\mu - 1) \cdot q_C}{2^{n+1}} + (q_L + 1) \left(2\mu q_E + \frac{(\mu - 1) \cdot q_C}{2}\right) / |\mathcal{R}| \\ \leq \frac{2\mu q_E(q_L + 1)}{|\mathcal{R}|} + \frac{(\mu - 1) \cdot q_C(q_L + 1)}{|\mathcal{R}|}$$
(15)

by  $|\mathcal{R}| \leq 2^n$ .

#### 4.2.4 Bounding the ratio

Fix a good transcript  $Q_x = (Q, \mathbf{R})$ . The probability that the ideal world is consistent with this transcript is given by Eq. (9). The probability that the real world is consistent with this transcript is

$$\frac{\Pr\left[\forall (\mathcal{O}, (\mathsf{idx}, w, i, b), z) \in \mathcal{Q} : \mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}, w, i, b) = z \mid E \vdash \mathcal{Q}\right]}{\prod_{k \in \{0,1\}^n} (2^n)_{|\mathcal{Q}[E,k]|}} \times \Pr[\mathbf{R}^* \xleftarrow{\$} (\mathcal{R})^u : \mathbf{R}^* = \mathbf{R}].$$
(16)

We can express the numerator of the above as

$$\begin{split} \prod_{j=1}^{q} \Pr[ \ \mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}, w_{j}, i_{j}, b_{j}) = z_{j} \\ | \ E \vdash \mathcal{Q} \land \forall \ell < j : \mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}_{\ell}, w_{\ell}, i_{\ell}, b_{\ell}) = z_{\ell}]. \end{split}$$

Note that  $\mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathrm{idx}_{j}, w_{j}, i_{j}, b_{j}) = z_{j}$  iff  $\widehat{\mathsf{MMO}}^{E}(R_{\mathrm{idx}_{j}} \oplus w_{j}, i_{j}) \oplus b_{j}R_{\mathrm{idx}_{j}} = z_{j}$ , i.e.,  $E(i_{j}, \sigma(R_{\mathrm{idx}_{j}} \oplus w_{j})) = \sigma(R_{\mathrm{idx}_{j}} \oplus w_{j}) \oplus b_{j}R_{\mathrm{idx}_{j}} \oplus z_{j}.$  Since the transcript is good, there is no query of the form  $(i_j, \sigma(R_{\mathsf{idx}_j} \oplus w_j), \star)$ in  $\mathcal{Q}[E]$  (since (B-1) does not occur), nor is  $E(i_j, \sigma(R_{\mathsf{idx}_j} \oplus w_j))$  determined by the fact that  $\mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}_{\ell}, w_{\ell}, i_{\ell}, b_{\ell}) = z_{\ell}$  for all  $\ell < j$  (since (B-2) does not occur). Similarly, there is no query of the form  $(i_j, \star, \sigma(R \oplus w_j) \oplus b_j R \oplus z_j)$ in  $\mathcal{Q}[E]$  (since (B-1) does not occur), nor is  $E^{-1}(i_j, \sigma(R_{\mathsf{idx}_j} \oplus w_j) \oplus b_j R_{\mathsf{idx}_j} \oplus z_j)$ determined by the fact that  $\mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}_{\ell}, w_{\ell}, i_{\ell}, b_{\ell}) = z_{\ell}$  for all  $\ell < j$  (since neither (B-2) nor (B-3) occurs). Thus, for all j we have

$$\begin{split} &\Pr[ \ \mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}, w_j, i_j, b_j) = z_j \\ &| \ E \vdash \mathcal{Q} \land \forall \ell < j : \mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}_\ell, w_\ell, i_\ell, b_\ell) = z_\ell] \geq 1/2^n. \end{split}$$

It follows that

$$\Pr\left[\forall (\mathcal{O}, (\mathsf{idx}, w, i, b), z) \in \mathcal{Q} : \mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}, w, i, b) = z \mid E \vdash \mathcal{Q}\right] \ge 1/2^{nq_C},$$

and so the probability that the real world is consistent with the transcript is at least the probability that the ideal world is consistent with the transcript. This means Eq. (15) already provides the final advantage bound. This completes the proof.

4.3 Proof of Eq. (14)

Recall that

$$S = \sum_{\mathcal{Q} \in \mathcal{T}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{CON}{\left| \mathcal{R}(\mathcal{Q}) \right|} \right),$$

where  $\mathcal{T}$  is the set of all attainable transcripts. Define

$$\ell_m := \max_{\mathcal{Q} \in \mathcal{T}} \left\{ |\mathcal{Q}| \right\}$$

as the maximal "length" of attainable transcripts in  $\mathcal{T}$ .

Below we proceed with four steps: (1) we introduce the notion of "chopped" attainable transcripts; (2) we present a "folding lemma" Lemma 2 regarding the sum over transcripts; (3) we study the "mostly folded" (weighted) sum over transcripts and establish an upper bound as the function of the involved coefficients; (4) we bound coefficients in the (weighted) sum. With these, we finally show how to derive Eq. (14).

## 4.3.1 "Chopped" attainable transcripts

For any integer  $\ell \in [1, \ell_m]$ , define a set of "chopped" attainable transcripts  $\mathcal{T}_{\ell}$  as

$$\mathcal{T}_{\ell} := \left\{ \mathcal{Q} : \mathcal{Q} \in \mathcal{T}, \ |\mathcal{Q}| \le \ell \right\} \\ \cup \left\{ \mathcal{Q} : |\mathcal{Q}| = \ell \text{ and } (\mathcal{Q}, \mathcal{Q}') \in \mathcal{T} \text{ for some suffix } \mathcal{Q}' \right\}.$$
(17)

Namely,

- (i) every transcript of length  $\leq \ell$  in  $\mathcal{T}$  is in  $\mathcal{T}_{\ell}$ , and
- (ii) for every transcript of length  $> \ell$  in  $\mathcal{T}$ , its prefix of length  $\ell$  is in  $\mathcal{T}_{\ell}$ .

Clearly,  $|\mathcal{T}_{\ell-1}| \leq |\mathcal{T}_{\ell}|$  for every  $\ell \in [2, \ell_m]$ .

Certainly, when  $\ell < \ell_m$ , transcripts in  $\mathcal{T}_{\ell}$  may not be "attainable", i.e., there may exist  $\mathcal{Q} \in \mathcal{T}_{\ell}$  with  $\Pr[T_{id} = \mathcal{Q}] = 0$ . However, they are "attainable" in the sense that for any  $\mathcal{Q} \in \mathcal{T}_{\ell}$ , there always exists some appropriate suffix  $\mathcal{Q}'$ such that  $\Pr[T_{id} = (\mathcal{Q}, \mathcal{Q}')] > 0$ . Consider the execution tree of the interaction between  $\mathcal{D}$  and the ideal world oracles, i.e., each time  $\mathcal{D}$  issues a query, the tree forks into as many branches as there are possible answers. Then, every  $\mathcal{Q} \in \mathcal{T}$  is associated with a complete path in this tree, while every  $\mathcal{Q} \in \mathcal{T}_{\ell}$  is associated with either a complete path or the prefix of several complete paths in this tree. Therefore, there always exists ideal world randomness  $(E, f, \mathbf{R})$ that leads  $\mathcal{D}$  to run along  $\mathcal{Q}$  (although  $\mathcal{D}$  may not terminate at the end of  $\mathcal{Q}$ ).

#### 4.3.2 Folding lemma

With the above, S is a (weighted) sum over the set  $\mathcal{T} = \mathcal{T}_{\ell_m}$ . The "folding lemma" states that S can be rewritten as weighted sums over smaller sets  $\mathcal{T}_{\ell_m-1}, \mathcal{T}_{\ell_m-2}, ..., \mathcal{T}_1$ .

**Lemma 2** For every  $\ell \in [2, \ell_m]$ , any weighted sum over  $\mathcal{T}_{\ell}$  can be rewritten as a weighted sum over the smaller set  $\mathcal{T}_{\ell-1}$ .

Formally, define

$$S_{\ell} := \sum_{\mathcal{Q} \in \mathcal{T}_{\ell}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, \ell) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right).$$
(18)

for some coefficient function  $\lambda(\cdot, \ell)$ . Then, there exists a coefficient function  $\lambda(Q, \ell - 1)$  such that

$$S_{\ell-1} := \sum_{\mathcal{Q} \in \mathcal{T}_{\ell-1}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, \ell - 1) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right) = S_{\ell}.$$
(19)

*Proof* To prove this, we partition  $\mathcal{T}_{\ell} = \mathcal{T}_{\ell,1} \cup \mathcal{T}_{\ell,2}$ , where:

 $\begin{aligned} &-\mathcal{T}_{\ell,1} = \left\{ \mathcal{Q} \in \mathcal{T}_{\ell}, \ |\mathcal{Q}| \leq \ell - 1 \right\} \text{ consists of the transcripts of length } \leq \ell - 1 \\ &\text{ in } \mathcal{T}_{\ell}, \text{ and} \\ &-\mathcal{T}_{\ell,2} = \left\{ \mathcal{Q} \in \mathcal{T}_{\ell}, \ |\mathcal{Q}| = \ell \right\} \text{ consists of the transcripts of length } \ell \text{ in } \mathcal{T}_{\ell}. \end{aligned}$ 

Then,

$$S_{\ell} = \sum_{\mathcal{Q}\in\mathcal{T}_{\ell}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, \ell) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right)$$
$$= \underbrace{\sum_{\mathcal{Q}\in\mathcal{T}_{\ell,1}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, \ell) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right)}_{S_{\ell,1}}$$

On Tweakable Correlation Robust Hashing against Key Leakages

$$+\underbrace{\sum_{\mathcal{Q}\in\mathcal{T}_{\ell,2}}\left(\Pr\left[(E,f,\mathbf{R})\vdash\mathcal{Q}\right]\times\frac{\lambda(\mathcal{Q},\ell)\times CON}{\left|\mathcal{R}(\mathcal{Q})\right|}\right)}_{S_{\ell,2}}.$$
(20)

By the definition of  $\mathcal{T}_{\ell-1}$ , it can be seen:

$$-\mathcal{T}_{\ell,1} \subseteq \mathcal{T}_{\ell-1}$$
, and

- for every 
$$\mathcal{Q} = (\text{prefix}, (T, Q, A)) \in \mathcal{T}_{\ell,2}$$
, the prefix prefix is in  $\mathcal{T}_{\ell-1}$ 

With this in mind, define  $\overline{\mathcal{T}_{\ell-1,2}}$  as the set of prefixes of transcripts in  $\mathcal{T}_{\ell,2}$ , i.e.,

$$\overline{\mathcal{T}_{\ell-1,2}} := \big\{ \mathsf{prefix} : \big( \mathsf{prefix}, (\mathsf{T}, \mathsf{Q}, \mathsf{A}) \big) \in \mathcal{T}_{\ell,2} \text{ for some } (\mathsf{T}, \mathsf{Q}, \mathsf{A}) \big\}.$$
(21)

To proceed, we claim two propositions as follows.

#### **Proposition 1**

$$\mathcal{T}_{\ell-1} = \mathcal{T}_{\ell,1} \sqcup \overline{\mathcal{T}_{\ell-1,2}} \tag{22}$$

**Proposition 2** The sum  $S_{\ell,2}$  defined in Eq. (20) can be rewritten as a sum over  $\overline{\mathcal{T}_{\ell-1,2}} = \mathcal{T}_{\ell-1} \setminus \mathcal{T}_{\ell,1}$ . In detail, there exists a coefficient function  $\lambda(\operatorname{prefix}, \ell-1)$  such that

$$S_{\ell,2} = \sum_{\mathcal{Q}\in\overline{\mathcal{T}_{\ell-1,2}}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, \ell-1) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right).$$

where

$$\begin{split} \lambda(\mathcal{Q}, \ell - 1) &= \\ \begin{cases} \max_{\mathsf{A}} \big\{ \lambda((\mathcal{Q}, (\mathsf{T}, \mathsf{Q}, \mathsf{A})), \ell) \big\} & \text{if } (\mathcal{Q}, (\mathsf{T}, \mathsf{Q}, \mathsf{A})) \in \mathcal{T}_{\ell, 2} \text{ and} \\ \mathsf{T} \in \{E, E^{-1}, \mathcal{O}\} \\ \lambda((\mathcal{Q}, (\mathcal{L}, \mathsf{Q}, 0)), \ell) + \lambda((\mathcal{Q}, (\mathcal{L}, \mathsf{Q}, 1)), \ell) & \text{if } (\mathcal{Q}, (\mathcal{L}, \mathsf{Q}, 0)) \in \mathcal{T}_{\ell, 2} \end{cases} \end{split}$$

To ease understanding, their proofs are deferred to the end of this subsection. Gathering the two propositions and Eq. (20) yields

$$\begin{split} S_{\ell} &= S_{\ell,1} + S_{\ell,2} = \sum_{\mathcal{Q} \in \mathcal{T}_{\ell,1}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, \ell) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right) \\ &+ \sum_{\mathcal{Q} \in \overline{\mathcal{T}_{\ell-1,2}}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, \ell - 1) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right) \\ &= \sum_{\mathcal{Q} \in \mathcal{T}_{\ell-1}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, \ell - 1) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right), \end{split}$$

where the coefficient function  $\lambda(\mathcal{Q}, \ell - 1)$  is defined as:

$$\lambda(\mathcal{Q}, \ell - 1) =$$

$$\begin{cases} \lambda(\mathcal{Q}, \ell) & \text{if } \mathcal{Q} \in \mathcal{T}_{\ell,1} \\ \max_{\mathsf{A}} \{ \lambda((\mathcal{Q}, (\mathsf{T}, \mathsf{Q}, \mathsf{A})), \ell) \} & \text{if } (\mathcal{Q}, (\mathsf{T}, \mathsf{Q}, \mathsf{A})) \in \mathcal{T}_{\ell,2} \text{ and} \\ \mathsf{T} \in \{ E, E^{-1}, \mathcal{O} \} \\ \lambda((\mathcal{Q}, (\mathcal{L}, \mathsf{Q}, 0)), \ell) + \lambda((\mathcal{Q}, (\mathcal{L}, \mathsf{Q}, 1)), \ell) & \text{if } (\mathcal{Q}, (\mathcal{L}, \mathsf{Q}, 0)) \in \mathcal{T}_{\ell,2} \end{cases}$$

$$(23)$$

This completes the proof (of Lemma 2).

Proof of Proposition 1. To prove  $\mathcal{T}_{\ell-1} = \mathcal{T}_{\ell,1} \sqcup \overline{\mathcal{T}_{\ell-1,2}}$ , we show that for every  $\mathcal{Q} \in \mathcal{T}_{\ell-1}$ , exactly one of the following holds:

 $\begin{array}{l} - \ \mathcal{Q} \in \underline{\mathcal{T}}_{\ell,1}; \\ - \ \mathcal{Q} \in \overline{\mathcal{T}}_{\ell-1,2}, \ \mathrm{i.e.}, \ \left(\mathcal{Q}, (\mathsf{T},\mathsf{Q},\mathsf{A})\right) \in \mathcal{T}_{\ell-1,2}. \end{array}$ 

The argument is as follows. Since  $\mathcal{Q} \in \mathcal{T}_{\ell-1}$ ,  $\mathcal{Q}$  is attainable with some randomness  $(E, f, \mathbf{R})$ . Assume that  $\mathcal{D}$  has obtained  $\mathcal{Q}$  by its first  $\ell-1$  queries. Since  $\mathcal{D}$  is deterministic, the next action has been fixed.

- If  $\mathcal{D}$  does not issue queries anymore, then  $|\mathcal{Q}| = \ell 1$  and  $\mathcal{Q} \in \mathcal{T}_{\ell,1}$ . Meanwhile, it necessarily holds  $(\mathcal{Q}, (\mathsf{T}, \mathsf{Q}, \mathsf{A})) \notin \mathcal{T}_{\ell}$  for all  $(\mathsf{T}, \mathsf{Q}, \mathsf{A})$ .
- Otherwise, assume that the next query of  $\mathcal{D}$  is  $(\mathsf{T}, \mathsf{Q})$ . Then  $(\mathcal{Q}, (\mathsf{T}, \mathsf{Q}, \mathsf{A})) \in \mathcal{T}_{\ell,2}$  for all valid answer  $\mathsf{A}$ , which means  $\mathcal{Q} = \overline{\mathcal{T}_{\ell-1,2}}$ . In this case, it cannot hold  $\mathcal{Q} \in \mathcal{T}_{\ell,1}$ .

This establishes the claim.

We remark that  $\mathcal{T}_{\ell,1} \cap \overline{\mathcal{T}_{\ell-1,2}} = \emptyset$  means that *attainable transcripts are prefix-free*, which seems an interesting general property in the information theoretic setting.

Proof of Proposition 2. Consider each  $Q \in T_{\ell,2}$  and assume Q = (prefix, (T, Q, A)), i.e., the latest query in Q is Q. We distinguish four cases.

- Case 1: T = O, i.e., Q = (idx, w, i, b) is a construction query. Then it is easy to see all the  $2^n$  transcripts

$$(\mathsf{prefix}, ig(\mathcal{O}, (\mathsf{idx}, w, i, b), zig)ig), \hspace{0.2cm} z \in \{0, 1\}^n$$

are attainable (because every  $z \in \{0,1\}^n$  can be returned by  $f(\mathsf{idx}, w, i, b)$ ) and are in  $\mathcal{T}_{\ell,2}$ . For all of them, it holds

$$\mathcal{R}((\mathsf{prefix}, (\mathcal{O}, (\mathsf{idx}, w, i, b), z))) = \mathcal{R}(\mathsf{prefix}),$$

since this set only depends on the key leaking query records, and the key leaking query records in these  $2^n$  transcripts are the same as those in **prefix**. Therefore, summing over these  $2^n$  transcripts yields

$$\begin{split} \sum_{\substack{(\mathsf{prefix},(\mathcal{O},(\mathsf{idx},w,i,b),z)), \ z\in\{0,1\}^n \\ \times \frac{\lambda(\big(\mathsf{prefix},\big(\mathcal{O},(\mathsf{idx},w,i,b),z\big)\big),\ell\big)\times CON}{|\mathcal{R}\big(\big(\mathsf{prefix},(\mathcal{O},(\mathsf{idx},w,i,b),z\big)\big),\ell\big)\times CON}\Big)} \end{split}$$

$$\begin{split} &\leq 2^n \times \Pr\big[(E, f, \mathbf{R}) \vdash \mathsf{prefix}\big] \times \frac{1}{2^n} \\ &\qquad \times \frac{\max_{z \in \{0,1\}^n} \big\{\lambda\big(\big(\mathsf{prefix}, \big(\mathcal{O}, (\mathsf{idx}, w, i, b), z\big)\big), \ell\big)\big\} \times CON}{|\mathcal{R}(\mathsf{prefix})|} \\ &= \Pr\big[(E, f, \mathbf{R}) \vdash \mathsf{prefix}\big] \times \frac{\lambda(\mathsf{prefix}, \ell - 1) \times CON}{|\mathcal{R}(\mathsf{prefix})|}, \end{split}$$

where  $\lambda(\operatorname{prefix}, \ell - 1) = \max_{z \in \{0,1\}^n} \{\lambda((\operatorname{prefix}, (\mathcal{O}, (\operatorname{idx}, w, i, b), z)), \ell)\}.$ - Case 2:  $\mathsf{T} = E$ , i.e.,  $\mathsf{Q} = (k, x)$  is a forward ideal cipher query. Let  $\mathcal{S}(\operatorname{prefix}) := \{y \in \{0,1\}^n : (k, \star, y) \in \operatorname{prefix}\}.$  Then, it can be seen all the  $2^n - |\mathcal{S}(\operatorname{prefix})|$  transcripts

$$(\operatorname{prefix}, (E, (k, x), y)), y \in (\{0, 1\}^n \setminus \mathcal{S}(\operatorname{prefix}))$$

are attainable (because every  $y \in (\{0,1\}^n \setminus S)$  can be returned by E(k,x)) and are in  $\mathcal{T}_{\ell,2}$ . For all of them, it holds  $\mathcal{R}((\mathsf{prefix}, (E, (k, x), y))) = \mathcal{R}(\mathsf{prefix})$ which resembles Case 1. Therefore, summing over these  $2^n - |\mathcal{S}(\mathsf{prefix})|$ transcripts yields

$$\begin{split} &\sum_{\substack{(\mathsf{prefix},(E,(k,x),y)), \ y \in \left(\{0,1\}^n \setminus \mathcal{S}(\mathsf{prefix})\right)}} \left( \Pr\left[(E,f,\mathbf{R}) \vdash \mathsf{prefix}\right] \\ &\times \Pr\left[E(k,x) = y \mid E \vdash \mathsf{prefix}\right] \times \frac{\lambda\left(\left(\mathsf{prefix},\left(E,(k,x),y\right)\right),\ell\right) \times CON\right)}{|\mathcal{R}\left(\left(\mathsf{prefix},(E,(k,x),y)\right)\right)|} \right) \\ &\leq \left(2^n - |\mathcal{S}(\mathsf{prefix})|\right) \times \Pr\left[(E,f,\mathbf{R}) \vdash \mathsf{prefix}\right] \times \frac{1}{2^n - |\mathcal{S}(\mathsf{prefix})|} \\ &\times \frac{\max_{y \in (\{0,1\}^n \setminus \mathcal{S}(\mathsf{prefix}))} \left\{\lambda\left(\left(\mathsf{prefix},(E,(k,x),y)\right),\ell\right)\right\} \times CON\right)}{|\mathcal{R}(\mathsf{prefix})|} \\ &= \Pr\left[(E,f,\mathbf{R}) \vdash \mathsf{prefix}\right] \times \frac{\lambda(\mathsf{prefix},\ell-1) \times CON}{|\mathcal{R}(\mathsf{prefix})|}, \end{split}$$

where  $\lambda(\operatorname{prefix}, \ell - 1) = \max_{y \in (\{0,1\}^n \setminus S(\operatorname{prefix}))} \{\lambda((\operatorname{prefix}, (E, (k, x), y)), \ell)\}.$ - Case 3:  $\mathsf{T} = E^{-1}$ , i.e.,  $\mathsf{Q} = (k, y)$  is a backward ideal cipher query. It is essentially the same as Case 2.

- Case 4:  $T = \mathcal{L}$ , i.e., Q = (idx, P) is a key leaking query. Then, both of the two transcripts

$$\big(\mathsf{prefix},(\mathcal{L},(\mathsf{idx},P),0)\big),\ \big(\mathsf{prefix},(\mathcal{L},(\mathsf{idx},P),1)\big)$$

are attainable and are in  $\mathcal{T}_{\ell,2}$ . Let

$$\begin{split} & \big((\mathcal{L}, (1, P_{1,1}), 1), \dots, (\mathcal{L}, (1, P_{1,t_1}), r_{1,t_1})\big), \\ & \dots, \\ & \big((\mathcal{L}, (\mathsf{idx}, P_{\mathsf{idx},1}), 1), \dots, (\mathcal{L}, (\mathsf{idx}, P_{\mathsf{idx}, t_{\mathsf{idx}}-1}), 1)\big), \\ & \dots, \\ & \big((\mathcal{L}, (u, P_{u,1}), 1), \dots, (\mathcal{L}, (u, P_{u,t_u}), r_{u,t_u})\big) \end{split}$$

be the list of key leaking queries to the 1st, ..., idx-th, ..., u-th user keys respectively and their answers recorded in prefix. Then, by our assumption of normalization, it holds

$$\begin{split} &\mathcal{R}\big(\big(\mathsf{prefix},(\mathcal{L},(\mathsf{idx},P),0)\big),\mathsf{idx}\big) = \mathcal{R}(P_{\mathsf{idx},t_{\mathsf{idx}}-1}) \backslash \mathcal{R}(P), \\ &\mathcal{R}\big(\big(\mathsf{prefix},(\mathcal{L},(\mathsf{idx},P),1)\big),\mathsf{idx}\big) = \mathcal{R}(P). \end{split}$$

Recall from Eq. (8) that, for j = 1, ..., idx - 1, idx + 1, ..., u,  $\mathcal{R}(\text{prefix}, j)$  is the set of keys  $R_j$  that fulfills the predicates queried to  $\mathcal{L}_{\mathbf{R}}(j, \cdot)$ .<sup>4</sup> Then, conditioned on  $(E, f, \mathbf{R}) \vdash \text{prefix}$ ,

- the key  $R_{\mathsf{idx}}$  is uniformly distributed in  $\mathcal{R}(P_{\mathsf{idx},t_{\mathsf{idx}}-1})$ , and
- for j = 1, ..., idx 1, idx + 1, ..., u, the key  $R_j$  is uniformly distributed in  $\mathcal{R}(\mathsf{prefix}, j)$ .

By these, we have

$$\begin{split} &\Pr\left[(E, f, \mathbf{R}) \vdash \left(\mathsf{prefix}, (\mathcal{L}, (\mathsf{idx}, P), 0)\right)\right] \\ &= \Pr\left[(E, f, \mathbf{R}) \vdash \mathsf{prefix}\right] \\ &\times \Pr\left[R_{\mathsf{idx}} \in \left(\mathcal{R}(P_{\mathsf{idx}, t_{\mathsf{idx}} - 1}) \backslash \mathcal{R}(P)\right) \mid (E, f, \mathbf{R}) \vdash \mathsf{prefix}\right] \\ &= \Pr\left[(E, f, \mathbf{R}) \vdash \mathsf{prefix}\right] \times \frac{|\mathcal{R}(P_{\mathsf{idx}, t_{\mathsf{idx}} - 1})| - |\mathcal{R}(P)|}{|\mathcal{R}(P_{\mathsf{idx}, t_{\mathsf{idx}} - 1})|}. \end{split}$$

Similarly,

$$\begin{split} &\Pr\big[(E, f, \mathbf{R}) \vdash \big(\mathsf{prefix}, (\mathcal{L}, (\mathsf{idx}, P), 1)\big)\big] \\ &= \Pr\big[(E, f, \mathbf{R}) \vdash \mathsf{prefix}\big] \times \frac{|\mathcal{R}(P)|}{|\mathcal{R}(P_{\mathsf{idx}, t_{\mathsf{idx}} - 1})|}. \end{split}$$

Therefore,

 $\text{with } \lambda(\mathsf{prefix}, \ell-1) = \lambda\big(\big(\mathsf{prefix}, (\mathcal{L}, (\mathsf{idx}, P), 0)\big), \ell\big) + \lambda\big(\big(\mathsf{prefix}, (\mathcal{L}, (\mathsf{idx}, P), 1)\big), \ell\big).$ 

<sup>&</sup>lt;sup>4</sup> Note that we don't know if  $r_{1,t_1}, ..., r_{u,t_u} = 1$  or not.

In summary, in every case, it holds

$$\begin{split} S_{\ell,2} &= \sum_{\mathcal{Q}\in\mathcal{T}_{\ell}, |\mathcal{Q}|=\ell} \left( \Pr\left[ (E,f,\mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q},\ell) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right) \\ &= \sum_{\mathsf{prefix}: (\mathsf{prefix}, (\mathsf{T},\mathsf{Q},\mathsf{A})) \in \mathcal{T}_{\ell}} \left( \Pr\left[ (E,f,\mathbf{R}) \vdash \mathsf{prefix} \right] \times \frac{\lambda(\mathsf{prefix},\ell-1) \times CON}{|\mathcal{R}(\mathsf{prefix})|} \right) \end{split}$$

for the function  $\lambda(\text{prefix}, \ell - 1)$  defined in the main claim. This completes the proof.

#### 4.3.3 The sum $S_1$

Lemma 2 "reduces"  $S = S_{\ell_m}$  to the "last" weighted sum

$$S_1 := \sum_{\mathcal{Q} \in \mathcal{T}_1} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, 1) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right).$$
(24)

It can be seen that transcripts in  $\mathcal{T}_1$  are all of the form  $((\mathsf{T}_1, \mathsf{Q}_1, \star))$ , and are all induced by the possible answers to the first query  $\mathsf{Q}_1$  of the distinguisher. Since  $\mathcal{D}$  is deterministic, this query is fixed and  $\mathcal{T}_1$  contains all the possible responses. By these, it turns out that  $S_1$  is a simple function of the coefficients  $\lambda(\cdot, 1)$ .

 ${\bf Lemma \ 3} \ {\it Let} \ {\mathcal T}_1 = \big\{ \big( ({\mathsf T}_1, {\mathsf Q}_1, {\mathsf A}_{1,1}), ({\mathsf T}_1, {\mathsf Q}_1, {\mathsf A}_{1,2}), ... \big) \big\}. \ {\it Then},$ 

$$S_{1} = \begin{cases} \frac{\max_{\mathsf{A} \in \{0,1\}^{n}} \left\{ \lambda((\mathcal{Q},(\mathsf{T}_{1},\mathsf{Q}_{1},\mathsf{A})),1) \right\} \times CON}{|\mathcal{R}|^{u}} & \text{if } \mathsf{T}_{1} \in \{E, E^{-1}, \mathcal{O}\} \\ \frac{\left( \lambda((\mathcal{Q},(\mathsf{T}_{1},\mathsf{Q}_{1},0)),1) + \lambda((\mathcal{Q},(\mathsf{T}_{1},\mathsf{Q}_{1},1)),1) \right) \times CON}{|\mathcal{R}|^{u}} & \text{if } \mathsf{T}_{1} = \mathcal{L} \end{cases}$$

$$(25)$$

*Proof* Depending on  $T_1$ , we distinguish four cases.

– Case 1:  $\mathsf{T}_1 = \mathcal{O}$ , i.e.,  $\mathsf{Q}_1 = (\mathsf{idx}, w, i, b)$  is a construction query. Then it is easy to see

$$\mathcal{T}_1 = \left\{ \left(\mathcal{O}, (\mathsf{idx}, w, i, b), z\right) \right\}_{z \in \{0, 1\}^n}.$$

For all of them, it holds  $\mathcal{R}((\mathcal{O}, (\mathsf{idx}, w, i, b), z)) = \mathcal{R}$ . Therefore,

$$S_{1} := \sum_{\mathcal{Q}\in\mathcal{T}_{1}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, 1) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right)$$
  
$$\leq 2^{n} \times \frac{1}{2^{n}} \times \frac{\max_{z \in \{0,1\}^{n}} \left\{ \lambda\left( \left(\mathcal{O}, (\mathsf{idx}, w, i, b), z\right), 1\right) \right\} \times CON}{|\mathcal{R}|^{u}}$$
  
$$= \frac{\max_{z \in \{0,1\}^{n}} \left\{ \lambda\left( \left(\mathcal{O}, (\mathsf{idx}, w, i, b), z\right), 1\right) \right\} \times CON}{|\mathcal{R}|^{u}}.$$

- Case 2:  $T_1 = E$ , i.e.,  $Q_1 = (k, x)$  is a forward ideal cipher query. Then it is easy to see

$$\mathcal{T}_1 = \left\{ \left( E, (k, x), y \right) \right\}_{y \in \{0, 1\}^n}.$$

In a similar vein to Case 1, we have

$$S_{1} := \sum_{\mathcal{Q}\in\mathcal{T}_{1}} \left( \Pr\left[ (E, f, \mathbf{R}) \vdash \mathcal{Q} \right] \times \frac{\lambda(\mathcal{Q}, 1) \times CON}{|\mathcal{R}(\mathcal{Q})|} \right)$$
$$\leq 2^{n} \times \frac{1}{2^{n}} \times \frac{\max_{y \in \{0,1\}^{n}} \left\{ \lambda\left( \left( E, (k, x), y \right), 1 \right) \right\} \times CON}{|\mathcal{R}|^{u}}$$
$$= \frac{\max_{y \in \{0,1\}^{n}} \left\{ \lambda\left( \left( E, (k, x), y \right), 1 \right) \right\} \times CON}{|\mathcal{R}|^{u}}.$$

– Case 3:  $\mathsf{T}_1 = E^{-1}$ , i.e.,  $\mathsf{Q}_1 = (k, y)$  is a backward ideal cipher query. It is essentially the same as Case 2.

- Case 4:  $T_1 = \mathcal{L}$ , i.e.,  $Q_1 = (idx, P)$  is a key leaking query. Then,

$$\mathcal{T}_1 = \big\{ (\mathcal{L}, (\mathsf{idx}, P), 0), \ (\mathcal{L}, (\mathsf{idx}, P), 1) \big\}.$$

The number of key vectors  $\mathbf{R} = (R_1, ..., R_u)$  such that  $P(R_{\mathsf{idx}}) = 0$ , resp.  $P(R_{\mathsf{idx}}) = 1$ , is  $(|\mathcal{R}| - |\mathcal{R}(P)|) \times |\mathcal{R}|^{u-1}$ , resp.  $|\mathcal{R}(P)| \times |\mathcal{R}|^{u-1}$ . Therefore,

$$\begin{split} &\sum_{r=0,1} \Pr\big[(E,f,\mathbf{R}) \vdash (\mathcal{L},(\mathsf{idx},P),r)\big] \times \frac{\lambda\big((\mathcal{L},(\mathsf{idx},P),r),1\big) \times CON}{\left|\mathcal{R}\big((\mathcal{L},(\mathsf{idx},P),r),\mathsf{idx}\big)\right| \times \left|\mathcal{R}\right|^{u-1}} \Big) \\ &= \Big(\frac{\big(|\mathcal{R}| - |\mathcal{R}(P)|\big) \times |\mathcal{R}|^{u-1}}{|\mathcal{R}|^u} \times \frac{\lambda\big((\mathcal{L},(\mathsf{idx},P),0),1\big) \times CON}{\left(|\mathcal{R}| - |\mathcal{R}(P)|\big) \times |\mathcal{R}|^{u-1}} + \frac{\left|\frac{\mathcal{R}(P)| \times |\mathcal{R}|^{u-1}}{|\mathcal{R}|^u} \times \frac{\lambda\big((\mathcal{L},(\mathsf{idx},P),1),1\big) \times CON}{|\mathcal{R}(P)| \times |\mathcal{R}|^{u-1}} \big) \\ &= \frac{\Big(\lambda\big((\mathcal{L},(\mathsf{idx},P),0),1\big) + \lambda\big((\mathcal{L},(\mathsf{idx},P),1),1\big)\big) \times CON}{|\mathcal{R}|^u}, \end{split}$$

These complete the proof.

#### 4.3.4 Bounding the coefficients

Recall that a basic condition is  $\lambda(\mathcal{Q}, \ell_m) = 1$  for any attainable transcript  $\mathcal{Q} \in \mathcal{T} = \mathcal{T}_{\ell_m}$ . With this and the above "folding lemma", we now establish upper bounds on the coefficients  $\lambda(\cdot, 1), ..., \lambda(\cdot, \ell_m)$  that appeared in the previous sections.

**Lemma 4** For any  $Q \in T_{\ell}$ ,  $|Q| = \ell$ , assume that if the interaction between D and the ideal world oracles yields Q for its first  $\ell$  queries, then D makes at most j key leaking queries subsequently. Then,  $\lambda(Q, \ell) \leq j + 1$ .

The lemma can also be stated as a property of the aforementioned execution tree. In detail, consider *any subtree* in the execution tree, and let  $\mathcal{Q}$ ,  $|\mathcal{Q}| = \ell$ , be the (partial) transcript corresponding to the path from the root of the execution tree to the root of the subtree. Then, if none of the path of this subtree has more than j key leaking queries, then the coefficient is bounded by  $\lambda(\mathcal{Q}, \ell) \leq j + 1$ .

Proof (Proof of Lemma 4) Towards a contradiction, assume that there exists such a  $\mathcal{Q}$  with  $\lambda(\mathcal{Q}, \ell) \geq j + 2$ . We distinguish between j = 0 and j > 0, since the former case also serves as a helpful intermediate result.

Base case: j = 0. Namely, after obtaining the transcript  $\mathcal{Q}, \mathcal{D}$  never queries  $\mathcal{L}_{\mathbf{R}}$  anymore. In this case, our assumption becomes  $\lambda(\mathcal{Q}, \ell) \geq 2$ . Since  $\mathcal{D}$  is deterministic, the next action is fixed.

If  $\mathcal{D}$  doesn't issue query anymore, then it actually has  $\mathcal{Q} \in \mathcal{T}$  is a ("complete") attainable transcript, and our assumption  $\lambda(\mathcal{Q}, \ell) \geq 2$  clearly contradicts the basic condition that  $\lambda(\mathcal{Q}, \ell_m) = \lambda(\mathcal{Q}, \ell)$  should have been 1.

If  $\mathcal{D}$  still makes queries, then the next query  $(\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1})$  is fixed, and it holds  $\mathsf{T}_{\ell+1} \neq \mathcal{L}$  by our assumption of j = 0. Therefore, Eq. (23) yields

$$\lambda(\mathcal{Q},\ell) = \max_{\mathsf{A}_{\ell+1}} \Big\{ \lambda \big( (\mathcal{Q}, (\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1}, \mathsf{A}_{\ell+1})), \ell+1 \big) \Big\},$$
(26)

and our assumption  $\lambda(\mathcal{Q}, \ell) \geq 2$  implies that there exists  $A_{\ell+1}^{\circ}$  such that  $\lambda((\mathcal{Q}, (\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1}, \mathsf{A}_{\ell+1}^{\circ})), \ell+1) \geq 2.$ 

We can now repeat our argument for  $(\mathcal{Q}, (\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1}, \mathsf{A}_{\ell+1}^{\circ}))$ , and it eventually implies the existence of some suffix such that  $(\mathcal{Q}, (\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1}, \mathsf{A}_{\ell+1}^{\circ}, \mathsf{suffix})) \in \mathcal{T} = \mathcal{T}_{\ell_m}$  is "complete" and  $\lambda((\mathcal{Q}, (\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1}, \mathsf{A}_{\ell+1}^{\circ}), \mathsf{suffix}), \ell') \geq 2$  for  $\ell' = |(\mathcal{Q}, (\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1}, \mathsf{A}_{\ell+1}^{\circ}), \mathsf{suffix})|$ . This contradicts the basic condition.

The case of j > 0. Namely, after obtaining the transcript  $\mathcal{Q}$ ,  $\mathcal{D}$  subsequently makes at most j + 1 queries to  $\mathcal{L}_{\mathbf{R}}$ . In this case, our assumption has  $\lambda(\mathcal{Q}, \ell) \geq j + 2 \geq 2$ . Since  $\mathcal{D}$  is deterministic, the next query  $(\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1})$  is fixed. We distinguish three cases as follows.

- Case 1:  $\mathcal{D}$  doesn't issue query anymore. Then it has  $\mathcal{Q} \in \mathcal{T}$ , and our assumption  $\lambda(\mathcal{Q}, \ell) \geq 2$  contradicts that  $\lambda(\mathcal{Q}, \ell_m) = \lambda(\mathcal{Q}, \ell)$  should have been 1.
- Case 2:  $T_{\ell+1} = \mathcal{L}$  is a key leaking query. Then, the answer has  $A_{\ell+1} \in \{0, 1\}$ , and Eq. (23) yields

$$\lambda(\mathcal{Q},\ell) = \lambda((\mathcal{Q},(\mathcal{L},\mathsf{Q}_{\ell+1},0)),\ell+1) + \lambda((\mathcal{Q},(\mathcal{L},\mathsf{Q}_{\ell+1},1)),\ell+1).$$

Note that if  $\mathcal{D}$  obtains  $(\mathcal{Q}, (\mathcal{L}, \mathbb{Q}_{\ell+1}, 0))$ , then the construction and key leaking oracles abort and  $\mathcal{D}$  cannot make key leaking queries anymore. Therefore,  $\lambda((\mathcal{Q}, (\mathcal{L}, \mathbb{Q}_{\ell+1}, 0)), \ell+1) = 1$  by our result on base case that has been established.

Therefore, our assumption  $\lambda(\mathcal{Q}, \ell) \ge j + 2$  implies  $\lambda((\mathcal{Q}, (\mathcal{L}, Q_{\ell+1}, 1)), \ell + 1) \ge j + 1.$ 

– Case 3:  $T_{\ell+1} \neq \mathcal{L}$ . In this case, Eq. (23) yields

$$\lambda(\mathcal{Q},\ell) = \max_{\mathsf{A}_{\ell+1}} \Big\{ \lambda \big( (\mathcal{Q}, (\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1}, \mathsf{A}_{\ell+1})), \ell+1 \big) \Big\}.$$
(27)

and our assumption  $\lambda(Q, \ell) \geq j + 2$  implies there exists  $A_{\ell+1}^{\circ}$  such that  $\lambda((Q, (\mathsf{T}_{\ell+1}, \mathsf{Q}_{\ell+1}, \mathsf{A}_{\ell+1}^{\circ})), \ell+1) \geq j+2.$ 

In summary, our assumption  $\lambda(Q, \ell) \ge j + 2$  implies that at least one of the following three holds:

(i)  $\mathcal{Q} \in \mathcal{T}$  while  $\lambda(\mathcal{Q}, \ell) \ge j + 2 \ge 2$ ; or

(ii) There exists  $Q' \in \mathcal{T}_{\ell+1}$ ,  $|Q'| = \ell$ , such that: (a) once obtaining Q',  $\mathcal{D}$  makes at most j-1 key leaking queries subsequently; and (b)  $\lambda(Q, \ell) \leq j+1$ ; or

(iii) There exists  $Q' \in \mathcal{T}_{\ell+1}$ ,  $|Q'| = \ell$ , such that: (a) once obtaining Q',  $\mathcal{D}$  makes at most j key leaking queries subsequently; and (b)  $\lambda(Q, \ell) \leq j+2$ ; or

In the second and third cases, we can repeat the argument for  $\mathcal{Q}'$ , and it will eventually implies the existence of some suffix such that  $(\mathcal{Q}, \mathsf{suffix}) \in \mathcal{T} = \mathcal{T}_{\ell_m}$ and  $\lambda((\mathcal{Q}, \mathsf{suffix}), \ell') \geq 2$  for  $\ell' = |(\mathcal{Q}, \mathsf{suffix})|$ . This contradicts the basic condition. By these, the assumption  $\lambda(\mathcal{Q}, \ell) \geq j + 2$  does not hold, which completes the proof.

4.3.5 Deriving Eq. (14)

By Lemmas 2 and 3, it holds

$$\begin{split} S &= S_{\ell_m} = S_{\ell_m - 1} = \ldots = S_1 \\ &= \begin{cases} \frac{\max_{A \in \{0,1\}^n} \left\{ \lambda((\mathcal{Q}, (\mathsf{T}_1, \mathsf{Q}_1, \mathsf{A})), 1) \right\} \times CON}{|\mathcal{R}|^u} & \text{if } \mathsf{T}_1 \in \{E, E^{-1}, \mathcal{O}\} \\ \frac{\left( \lambda((\mathcal{Q}, (\mathsf{T}_1, \mathsf{Q}_1, 0)), 1) + \lambda((\mathcal{Q}, (\mathsf{T}_1, \mathsf{Q}_1, 1)), 1) \right) \times CON}{|\mathcal{R}|^u} & \text{if } \mathsf{T}_1 = \mathcal{L} \end{cases} \end{split}$$

Finally:

- − When  $\mathsf{T}_1 \in \{E, E^{-1}, \mathcal{O}\}$ , Lemma 4 implies  $\lambda(((\mathsf{T}_1, \mathsf{Q}_1, \mathsf{A})), 1) \leq q_L + 1$  for any valid answer  $\mathsf{A}$ , and thus  $S = S_1 \leq q_L + 1$ ;
- When  $\mathsf{T}_1 = \mathcal{L}$ , Lemma 4 implies  $\lambda(((\mathsf{T}_1, \mathsf{Q}_1, 0)), 1) = 1$  and  $\lambda(((\mathsf{T}_1, \mathsf{Q}_1, \mathsf{A})), 1) \leq q_L$ , and thus  $S = S_1 \leq q_L + 1$ .

These complete the proof for Eq. (14).

## 4.4 Attacks with Matching Complexities

We first present two attacks in the single-user TCCRL setting in Sect. 4.4.1. We then exhibit two attacks in the multi-user muTCCRL setting in Sect. 4.4.2.

## 4.4.1 Attacks in the single-user setting

Since there is no multiple users, we omit the user index idx from the oracle inputs to  $\mathcal{O}$  and  $\mathcal{L}$ .

Birthday attack. The bound in Theorem 1 indicates the existence of attacks making  $q_E$  queries to E and  $q_L$  queries to the key leaking oracle with  $q_E q_L \approx |\mathcal{R}|$ . We now exhibit such an attack. To this end, assume  $\mathcal{R} = \{0, 1\}^n$  for simplicity. For any fixed value of  $q_L$ , let  $\ell = \lceil \log_2 q_L \rceil$ , let  $\lfloor j \rfloor_{\ell}$  be the  $\ell$ -bit encoding of the integer j, and let

$$\mathcal{R}_j = \left\{ R \in \{0,1\}^n : \mathsf{leftbits}_\ell(R) = [j]_\ell \right\}.$$
(28)

Then,  $\mathcal{R} = \{0, 1\}^n = \bigcup_{j=0}^{2^{\ell}-1} \mathcal{R}_j$ . Based on this, we define a series of predicates: for any  $j \in \{0, ..., 2^{\ell} - 1\},$ 

$$P_j(R) = 1$$
 if and only if  $R \notin \mathcal{R}_j$ .

With the above preparations, an attack could proceed as follows.

- 1. Choose (w, i, 0) in arbitrary and query  $\mathcal{O}_R^{\text{TCCRL}}(w, i, 0) \to y$  to obtain y.
- 2. For  $j = 0, ..., 2^{\ell} 1$ , query  $\mathcal{L}_R(P_j)$  to see if  $R \in \mathcal{R}_j$ , till the oracle  $\mathcal{L}_R$  aborts. Note that abortion always occurs since  $\bigcup_{j=0}^{2^{\ell}-1} \mathcal{R}_j = \{0,1\}^n$ .
- 3. When  $\mathcal{L}_R$  aborts, we know  $R \in \mathcal{R}_j$  by the definitions, i.e.,  $\mathsf{leftbits}_\ell(R) = [j]_\ell$ . This has significantly reduced the possible key space.
- 4. Let  $\mathcal{U} := w \oplus \mathcal{R}_j$ . Query  $E(i, u) \to v$  for all  $u \in \mathcal{U}$   $(q_E = 2^{n-\ell}$  queries in total). Let  $E(i, u^*) \to v^* = y$ , then we can recover R via  $R = w \oplus u^*$ .

This attack consumes 1 construction query (consequently, the limitation enforced by  $\mu$  is fulfilled),  $q_L$  key leaking oracle queries and  $2^{n-\ell} = 2^n/q_L$  ideal cipher queries, and succeeds with probability roughly 1. Therefore, the  $n-\log_2 q_L$ bits provable security is tight, and security loss is significant when  $q_L$  is large.

Attack using Linear masking predicates. As mentioned in Sect. 4.1,  $q_L$  can be rather limited in concrete scenarios. For this, consider the linear masking predicates discussed by Roy [23]. In detail, it requires that for every leaking query P there exists  $a \in \{0, 1\}^n$  such that  $P(R) = \langle a, R \rangle$ . In this case, every non-trivial key leaking query halves the size of the possible key space, and  $q_L$  is essentially restricted to  $q_L \leq n$ . Concrete security is thus ensured up to  $\frac{|\mathcal{R}|}{\mu(n+1)}$  ideal cipher queries and  $2^n/\mu$  construction queries. To have a more fine-grained result, we provide a concrete attack as follows.

To have a more fine-grained result, we provide a concrete attack as follows. Again, assume  $\mathcal{R} = \{0, 1\}^n$  for simplicity. We define a series of predicates: for any  $j \in \{1, 2, ..., n\}$ ,

$$P_j(R) = 1 \text{ if and only if } \langle [2^{j-1}]_n, R \rangle = 1.$$
(29)

With the above preparations, an attack could proceed as follows.

- 1. Choose (w, i, 0) in arbitrary and query  $\mathcal{O}_R^{\text{TCCRL}}(w, i, 0) \to y$  to obtain y. 2. For j = 1, 2, ..., n, query  $\mathcal{L}_R(P_j)$  to see if  $\langle [2^{j+1}]_n, R \rangle = 1$ :
  - When  $\mathcal{L}_R$  aborts, we know:
    - The rightmost j 1 bits of R are all 1, and
    - The *j*-th rightmost bit of R is 0.

This has reduced the possible key space to  $2^{n-j}$ .

- Let  $\mathcal{R}^* := \{R \in \{0,1\}^n : \mathsf{rightbits}_{\ell}(R) = [2^{j-1} 1]_j\}$  and  $\mathcal{U} := w \oplus \mathcal{R}^*$ . Query  $E(i, u) \to v$  for all  $u \in \mathcal{U}$  ( $2^{n-j}$  queries in total). Let  $E(i, u^*) \to v^* = y$ , then we can recover R via  $R = w \oplus u^*$ .
- If  $\mathcal{L}_R$  never aborts, then  $R = [2^n 1]_n$ , i.e., all bits of R are 1. This recovers  $R^{5}$

This attack consumes 1 construction query and has roughly 1 success probability. We now calculate the expectations of its leaking oracle and ideal cipher query complexities. To this end, note that for any  $j \in \{1, ..., n\}$ , the probability to have

$$P_j(R) = 0 \land P_{j-1}(R) = 1 \land \dots \land P_1(R) = 1$$
(30)

is  $\frac{1}{2^j}$ . When the "right" key satisfies Eq. (30), the attack consumes j key leaking queries and  $2^{n-j}$  ideal cipher queries.

Finally, when the "right" key satisfies

$$P_n(R) = 1 \land P_{n-1}(R) = 1 \land \dots \land P_1(R) = 1$$
(31)

(the probability is  $1/2^n$ ), the attack consumes n leaking oracle queries and 1 ideal cipher queries. Therefore,

$$\mathbb{E}[q_L] = \left(\sum_{j=1}^n \frac{j}{2^j}\right) + \frac{n}{2^n} = \frac{1 - \frac{1}{2^n}}{1 - \frac{1}{2}} + \frac{n}{2^{n-1}} \le 2 + \frac{n}{2^{n-1}} \approx 2,$$
$$\mathbb{E}[q_E] = \left(\sum_{j=1}^n \frac{2^{n-j}}{2^j}\right) + \frac{1}{2^n}$$
$$= 2^n \times \left(\left(\sum_{j=1}^n \frac{1}{4^n}\right) + \frac{1}{4^n}\frac{1}{4^n}\right) \le 2^n \times \left(\frac{1}{3} + \frac{1}{4^n}\right) \approx 2^n/3.$$

The expected complexities are consistent with the bound in Theorem 1 as well.

#### 4.4.2 Attacks in the multi-user setting

Birthday attack using 1 leaking query per user. In the multi-user setting, let  $q_{L,\text{idx}}$  be the number of queries to the idx-th user's key leaking oracle. Then,  $q_L = q_{L,1} + \ldots + q_{L,u}$ . We now show that even if  $q_{L,\text{idx}}$  is restricted to 1 for every idx, there still exists a birthday attack with  $q_E q_L \approx |\mathcal{R}|$ . Therefore, the present of multiple users eases attacks.

Again, assume  $\mathcal{R} = \{0, 1\}^n$  for simplicity. For any fixed value of  $q_L$  such that  $q_L \leq u$ , fix  $\mathcal{R}^\circ \subset \mathcal{R}$  with  $|\mathcal{R}^\circ| = 2^n/q_L$ . Define

$$P(R) = 1$$
 if and only if  $R \in \mathcal{R}^{\circ}$ .

Our attack proceeds as follows.

<sup>&</sup>lt;sup>5</sup> We stress that this is insufficient for distinguishing, since the same result may be obtained in the ideal world. To distinguish, one could query the ideal cipher  $E(i, \sigma(w \oplus [2^n - 1]_n)) \rightarrow y'$  and check if y' = y. Crucially, this distinguishing attack has  $q_E \geq 1$ , and the complexities are matched by Theorem 1.

- For idx ∈ {1,...,u}, query L<sub>R</sub>(idx, P), till R<sub>idx</sub> ∈ R°, i.e., L<sub>R</sub>(idx, P) does not abort. Let idx° be the first index such that L<sub>R</sub>(idx°, P) does not abort.
   Choose (w, i, 0) in arbitrary and query O<sub>R</sub><sup>muTCCRL</sup>(idx°, w, i, 0) → y =
- 2. Choose (w, i, 0) in arbitrary and query  $\mathcal{O}_{\mathbf{R}}^{\operatorname{interm}}(\operatorname{idx}^{*}, w, i, 0) \to y = \widehat{\mathsf{MMO}}^{E}(w \oplus R_{\operatorname{idx}^{\circ}}, i)$  to obtain y.
- 3. Let  $\mathcal{U} := w \oplus \mathcal{R}^{\circ}$ . Query  $E(i, u) \to v$  for all  $u \in \mathcal{U}$  ( $|\mathcal{R}^{\circ}|$  queries in total). Let  $E(i, u^*) \to v^* = y$ , then we can recover R via  $R = w \oplus u^*$ .

This attack consumes 1 construction query,  $q_L$  key leaking oracle queries (1 query per user) and  $|\mathcal{R}^\circ| = 2^n/q_L$  ideal cipher queries. Since  $\Pr[R \stackrel{s}{\leftarrow} \{0,1\}^n : R \in \mathcal{R}^\circ] = |\mathcal{R}^\circ|/2^n = 1/q_L$ , it is expected to have at least 1 user index idx° such that  $\mathcal{L}_{\mathbf{R}}(\operatorname{idx}^\circ, P)$  does not abort and  $R_{\operatorname{idx}^\circ} \in \mathcal{R}^\circ$ . By querying  $E(i, u) \to v$  for all  $u \in \mathcal{U}$ , one can then recover the key  $R_{\operatorname{idx}^\circ}$ . Since  $q_L q_E = 2^n$ , this roughly matches the bound in Theorem 1.

Linear masking predicates in multi-user setting. Consider the aforementioned linear masking predicates discussed by Roy [23]. Again, assume  $\mathcal{R} = \{0, 1\}^n$  for simplicity. Recall from Eq. (29) for the definition of the predicate  $P_j$ . Let  $\ell = \lfloor \log_2 u \rfloor$ . With the above preparations, we provide an attack as follows.

- 1. For  $idx = 1, ..., u, j = 1, 2, ..., \ell$ , query  $\mathcal{L}_{\mathbf{R}}(idx, P_j)$  to see if  $\langle [2^{j+1}]_n, R_{idx} \rangle = 1$ , till  $\mathcal{L}_{\mathbf{R}}(idx, \cdot)$  aborts.
- 2. Let  $\mathsf{idx}^\circ$  be the smallest user index such that  $\mathcal{L}_{\mathbf{R}}(\mathsf{idx}, \cdot)$  does not abort. Choose (w, i, 0) in arbitrary and query  $\mathcal{O}_{\mathbf{R}}^{\mathrm{muTCCRL}}(\mathsf{idx}^\circ, w, i, 0) \to y = \widehat{\mathsf{MMO}}^E(w \oplus R_{\mathsf{idx}^\circ}, i)$  to obtain y.
- 3. Let  $\mathcal{R}^* := \{R \in \{0,1\}^n : \mathsf{rightbits}_{\ell}(R) = [2^{\ell} 1]_{\ell}\}$  and  $\mathcal{U} := w \oplus \mathcal{R}^*$ . Query  $E(i, u) \to v$  for all  $u \in \mathcal{U}$   $(2^{n-\ell}$  queries in total). Let  $E(i, u^*) \to v^* = y$ , then we can recover  $R_{\mathsf{idx}^\circ}$  via  $R_{\mathsf{idx}^\circ} = w \oplus u^*$ .

As analyzed before, for every idx the probability that  $\mathcal{L}_{\mathbf{R}}(\operatorname{idx}, \cdot)$  does not abort is  $1/2^{\ell}$ . Since  $\ell = \lfloor \log_2 u \rfloor$ , we are expected to have some index idx° such that  $\mathcal{L}_{\mathbf{R}}(\operatorname{idx}^\circ, \cdot)$  does not abort. Therefore, the success probability is roughly 1. This attack consumes 1 construction query,  $u \lfloor \log_2 u \rfloor$  leaking oracle queries ( $\log_2 u$ queries per user) and  $2^{n-\ell} \approx 2^n/u$  ideal cipher queries. The complexities are consistent with the bounds in Theorem 1 (to a large extent).

#### **5** Oblivious-Transfer Extension

As application of Theorem 1, in this section we show an OT extension protocol with non-trivial multi-user security. Following [7], we also focus on the random-OT-to-standard-OT transformation and its malicious security, which suffices for an instructive example. Following [12], we also present all our protocols in the  $\mathcal{F}_{\Delta-\text{ROT}}$ -hybrid model: see Fig. 1. This ideal functionality provides an abstraction of the first phase of OT extension.

# **Functionality** $\mathcal{F}_{\Delta-\mathsf{ROT}}(m,k)$

**Initialize:** Upon receiving (Init,  $\Delta$ ) from  $\mathsf{P}_{\mathsf{A}}$  with  $\Delta \in \{0, 1\}^k$ , and (Init) from  $\mathsf{P}_{\mathsf{B}}$ , store  $\Delta$  and ignore subsequent Init commands.

Set up correlations: Upon receiving  $(x_1, \ldots, x_m)$  from  $\mathsf{P}_{\mathsf{B}}$  with  $x_i \in \{0, 1\}$  do:

- 1. For each  $i \in \{1, ..., m\}$ , sample uniform  $\mathbf{a}_i, \mathbf{b}_i \in \{0, 1\}^k$  such that  $\mathbf{a}_i \oplus \mathbf{b}_i = x_i \cdot \Delta$ .
- 2. If  $P_A$  is corrupted, wait for A to send  $\{a_i\}$  and recompute  $\{b_i\}$  accordingly. If  $P_B$  is corrupted, wait for A to send  $\{b_i\}$  and recompute  $\{a_i\}$  accordingly.
- 3. Send  $\{\mathbf{a}_i\}$  to  $\mathsf{P}_{\mathsf{A}}$  and  $\{\mathbf{b}_i\}$  to  $\mathsf{P}_{\mathsf{B}}$ .

**Global key query:** If  $\mathsf{P}_{\mathsf{B}}$  is corrupted then  $\mathcal{A}$  can send a predicate  $P : \{0,1\}^k \to \{0,1\}$  to the functionality after initialization but before sending its input. If  $P(\Delta) = 1$ , the functionality sends 1 to  $\mathcal{A}$ ; otherwise, the functionality aborts and notifies  $\mathsf{P}_{\mathsf{A}}$ .

**Fig. 1:** Functionality  $\mathcal{F}_{\Delta-ROT}$ .

**Functionality**  $\mathcal{F}_{S-OT}(m, n)$ 

Upon receiving  $((\mathbf{m}_1^0, \mathbf{m}_1^1), \dots, (\mathbf{m}_m^0, \mathbf{m}_m^1))$  from  $\mathsf{P}_{\mathsf{A}}$  with  $\mathbf{m}_i^b \in \{0, 1\}^n$  for all  $i \in \{1, ..., m\}$ and  $b \in \{0, 1\}$  and  $(x_1, \dots, x_m)$  from  $\mathsf{P}_{\mathsf{B}}$  with  $x_i \in \{0, 1\}$ , send  $\{\mathbf{m}_i^{x_i}\}$  to  $\mathsf{P}_{\mathsf{B}}$ .

Fig. 2: Functionality  $\mathcal{F}_{S-OT}$  for standard OT.

# **Protocol** $\prod_{s-ot}^{m,k,n} (k < n)$

**Inputs:**  $P_A$  has  $(\mathbf{m}_1^0, \mathbf{m}_1^1), \dots, (\mathbf{m}_m^0, \mathbf{m}_m^1)$  with  $\mathbf{m}_i^b \in \{0, 1\}^n$  for all  $i \in \{1, ..., m\}$  and  $b \in \{0, 1\}$ , and  $P_B$  has  $x_1, \dots, x_m$  with  $x_i \in \{0, 1\}$ .

#### **Protocol:**

- 1.  $\mathsf{P}_{\mathsf{A}}$  chooses uniform  $\Delta \stackrel{\$}{\leftarrow} \{0,1\}^k$  and sends (Init,  $\Delta$ ) to  $\mathcal{F}_{\Delta-\mathsf{ROT}}$ ;  $\mathsf{P}_{\mathsf{B}}$  sends (Init) to  $\mathcal{F}_{\Delta-\mathsf{ROT}}$ .
- 2.  $\mathsf{P}_{\mathsf{B}}$  sends  $(x_1, \ldots, x_m)$  to  $\mathcal{F}_{\Delta-\mathsf{ROT}}$ , which returns  $\mathbf{a}_1, \ldots, \mathbf{a}_m$  to  $\mathsf{P}_{\mathsf{A}}$  and  $\mathbf{b}_1, \ldots, \mathbf{b}_m$  to  $\mathsf{P}_{\mathsf{B}}$ .

3. Player  $\mathsf{P}_{\mathsf{A}}$  chooses  $IV \stackrel{\$}{\leftarrow} \{0, 1, ..., 2^n - 1\}$ , and computes, for all  $i \in \{1, ..., m\}$ ,

$$\mathbf{c}_{i}^{0} := H(\mathbf{a}_{i}, IV \oplus [i]_{n}) \oplus \mathbf{m}_{i}^{0}, \\ \mathbf{c}_{i}^{1} := H(\mathbf{a}_{i} \oplus \Delta, IV \oplus [i]_{n}) \oplus \mathbf{m}_{i}^{1}$$
(32)

P<sub>A</sub> then sends  $IV, \mathbf{c}_1^0, \mathbf{c}_1^1, ..., \mathbf{c}_m^0, \mathbf{c}_m^0$  to P<sub>B</sub>. 4. P<sub>B</sub> then computes  $\mathbf{m}_i^{x_i} := \mathbf{c}_i^{x_i} \oplus H(\mathbf{b}_i, IV \oplus [i]_n)$  for all  $i \in \{1, ..., m\}$ , and outputs  $(\mathbf{m}_1^{x_1}, ..., \mathbf{m}_m^{x_m})$ . Player P<sub>A</sub> outputs  $\perp$ .

Fig. 3: Protocol  $\prod_{S-OT}^{m,k,n}$  in the  $\mathcal{F}_{\Delta-ROT}$ -hybrid model.

#### 5.1 Multi-user security definition of 2PC malicious security

Fig. 2 describes the standard OT functionality  $\mathcal{F}_{\mathsf{S-OT}}$ . Ideal functionalities proceed in rounds of simultaneous inputs, for which they produce (simultaneously) outputs. A functionality  $\mathcal{F}$  offers three interfaces two are to the players  $P_A$  and  $P_B$ , and the third to the adversary  $\mathcal{A}$ . In each round of each protocol instance, either (1) one party sends a message to the other party, or (2) they simultaneously interact with the functionality  $\mathcal{F}$ . In the multi-user setting, we are interested in running u (independent initiated) instances of a (synchronous) two-party hybrid-model protocol  $\Pi^{(1)} =$  $(\mathsf{P}_{\mathsf{A},1},\mathsf{P}_{\mathsf{B},1}),...,\Pi^{(u)} = (\mathsf{P}_{\mathsf{A},u},\mathsf{P}_{\mathsf{B},u})$  accessing a functionality  $\mathcal{F}$  and implementing u independent instances of a target functionality  $\mathcal{G}$ . We remark that while the u instances are accessing the same  $\mathcal{F}$ , they initiate  $\mathcal{F}$  with independently chosen inputs.

We will distinguish now the real-world from the ideal-world execution. Both of them are parameterized by a set Corr  $\subsetneq \{P_{A,1}, P_{B,1}, ..., P_{A,u}, P_{B,u}\}$  of corrupted parties controlled by the adversary  $\mathcal{A}$ . For each  $idx \in \{1, ..., u\}$ , the case of both  $\mathsf{P}_{A,idx} \in \mathsf{Corr}$  and  $\mathsf{P}_{B,idx} \in \mathsf{Corr}$  is uninteresting. Since we are in the malicious setting, we require that exactly one of  $\mathsf{P}_{A,idx}$  and  $\mathsf{P}_{B,idx}$  falls in Corr.

- **Real-world execution.** Initially, we fix the input(s)  $X_{\overline{\text{Corr}}}$  of the uncorrupted parties. Then, we run the *u* protocol instances  $\Pi^{(1)}, ..., \Pi^{(u)}$ , and the adversary (1) can choose the messages meant to be sent by the corrupted players (if any) in the protocol instances  $\Pi^{(1)}, ..., \Pi^{(u)}$ , (2) has access to the player's interface in  $\mathcal{F}$ , and (3) it has access to  $\mathcal{A}$ 's dedicated interface in  $\mathcal{F}$ , as well as to all messages sent in the *u* protocol instances. Finally, the adversary outputs some value *z*. We let  $\mathsf{REAL}_{\mathsf{Corr},\mathcal{A}}^{\Pi^{(1)},...,\Pi^{(u)},\mathcal{F}}(X_{\overline{\mathsf{Corr}}}) = (X_{\overline{\mathsf{Corr}}}, z)$ . **Ideal-world execution.** Here, we consider *u* instances  $\mathcal{G}^{(1)}, ..., \mathcal{G}^{(u)}$ , and
- Ideal-world execution. Here, we consider u instances  $\mathcal{G}^{(1)}, ..., \mathcal{G}^{(u)}$ , and supply the input(s)  $X_{\overline{\text{Corr}}}$  to their corresponding interfaces. The adversary  $\mathcal{A}$  interacts with a simulator  $\mathcal{S}$ , which can use the interfaces of  $\mathcal{G}^{(1)}, ..., \mathcal{G}^{(u)}$ for corrupted parties, as well as the adversarial interface.  $\mathcal{A}$  will produce an output z, and we define  $\mathsf{IDEAL}_{\mathsf{Corr},\mathcal{A},\mathcal{S}}^{\mathcal{G}^{(u)}}(X_{\overline{\mathsf{Corr}}}) = (X_{\overline{\mathsf{Corr}}}, z)$ .

We then define

$$\begin{split} \mathbf{Adv}_{\Pi,\mathsf{Corr},u}^{(\mathcal{F}\to\mathcal{G})\text{-}\mathrm{nu-mpc}}\left(\mathcal{A},\mathcal{D},\mathcal{S},X_{\overline{\mathsf{Corr}}}\right) \\ &:=\Pr\left[\mathcal{D}\big(\mathsf{REAL}_{\mathsf{Corr},\mathcal{A}}^{\Pi^{(1)},\ldots,\Pi^{(u)},\mathcal{F}}(X_{\overline{\mathsf{Corr}}})\big)=1\right]-\Pr\left[\mathcal{D}\big(\mathsf{IDEAL}_{\mathsf{Corr},\mathcal{A},\mathcal{S}}^{\mathcal{G}^{(1)},\ldots,\mathcal{G}^{(u)}}\left(X_{\overline{\mathsf{Corr}}}\right)\right)=1\right]. \end{split}$$

To establish security, we need to show that for any adversary  $\mathcal{A}$ , there exists a simulator  $\mathcal{S}$  such that  $\mathbf{Adv}_{\Pi,\mathsf{Corr},u}^{(\mathcal{F}\to\mathcal{G})-\mathsf{mu-mpc}}(\mathcal{A},\mathcal{D},\mathcal{S},X_{\overline{\mathsf{Corr}}})$  is sufficiently small.

#### 5.2 OT extension with non-trivial multi-user security

We consider the random-OT-to-standard-OT transformation of Guo et al. [12, Fig. 3] that implements  $\mathcal{F}_{\mathsf{S}-\mathsf{OT}}(m,n)$  from  $\mathcal{F}_{\Delta-\mathsf{ROT}}(m,k)$  using a tweakable correlation robust hash function  $H: \{0,1\}^k \times \{0,1\}^n \to \{0,1\}^n$ , and improve its multi-user security by introducing a random IV (which is inspired by [11]). Our improved protocol  $\prod_{\mathsf{S}-\mathsf{OT}}^{m,k,n}$  is given in Fig. 3. Its malicious security is given below.

**Theorem 2** For every adversary  $\mathcal{A}$  that corrupts at most C receivers, every distinguisher  $\mathcal{D}$ , there exists a simulator  $\mathcal{S}$  and an adversary  $\mathcal{B}$  such that for

every

$$X = \left( (\mathbf{m}_{1,1}^{0}, \mathbf{m}_{1,1}^{1}), \dots, (\mathbf{m}_{1,m}^{0}, \mathbf{m}_{1,m}^{1}), \\ \dots, \\ (\mathbf{m}_{u,1}^{0}, \mathbf{m}_{u,1}^{1}), \dots, (\mathbf{m}_{u,m}^{0}, \mathbf{m}_{u,m}^{1}) \right),$$
(33)

it holds

$$\mathbf{Adv}_{\Pi_{\mathrm{OT}}^{m,k,n},\mathsf{Corr},u}^{(\mathcal{F}\to\mathcal{G})\operatorname{-mu-mpc}}(\mathcal{A},\mathcal{D},\mathcal{S},X) \leq \mathbf{Adv}_{H,\{0,1\}^k,\mathcal{P}_{\mathsf{free}},u,\mu}^{\mathrm{muTCCRL}}(\mathcal{B}),$$

where  $\mathcal{F} = \mathcal{F}_{\Delta-\text{ROT}}(m,k)$  and  $\mathcal{G} = \mathcal{F}_{\text{S-OT}}(m,n)$ . Here,  $\mathcal{B}$  makes at most  $u \cdot m$  distinct queries to its first oracle  $\mathcal{O}_{\mathbf{R}}^{\text{muTCCRL}}/f$ , at most C queries to its key leaking oracle  $\mathcal{L}_{\mathbf{R}}$  and at most  $q_{\mathcal{A}} + q_{\mathcal{D}} + u \cdot m \cdot q_{H}$  to the ideal cipher E, where  $q_{\mathcal{A}}$  and  $q_{\mathcal{D}}$  are the number of ideal-primitive queries of  $\mathcal{A}$  and  $\mathcal{D}$ 's, respectively, and  $q_H$  is the number of ideal-primitive queries in one evaluation of H. When H is  $\widehat{\mathsf{MMO}}^E$ , for any threshold  $\mu$  we further have (note that  $q_H = 1$ )

$$\mathbf{Adv}_{\Pi_{OT}^{m,k,n},\mathsf{Corr},u}^{(\mathcal{F}\to\mathcal{G})-\mathrm{nu-mpc}}(\mathcal{A},\mathcal{D},\mathcal{S},X) \leq \frac{2\mu(q_{\mathcal{A}}+q_{\mathcal{D}}+u\cdot m)(C+1)}{2^{k}} + \frac{(\mu-1)\cdot u\cdot m(C+1)}{2^{k}} + \frac{(u\cdot m)^{\mu+1}}{(\mu+1)!\cdot 2^{\mu n}}.$$
(34)

Discussion. Injecting Theorem 1 into the single-user bound of Chen and Tessaro [7],  $\Pi_{\text{OT}}^{m,k,n}$  achieves single-user security of

$$\frac{2\mu(q_{\mathcal{A}}+q_{\mathcal{D}}+m)(C+1)}{2^{k}} + \frac{(\mu-1)m(C+1)}{2^{k}} + \frac{m^{\mu+1}}{(\mu+1)! \cdot 2^{\mu n}}$$

(note that C = 1 in the single-user setting.) By this, a naïve hybrid argument implies multi-user security of

$$\frac{2\mu \cdot u(q_{\mathcal{A}} + q_{\mathcal{D}} + m)}{2^k} + \frac{(\mu - 1) \cdot m \cdot u}{2^k} + \frac{u \cdot m^{\mu + 1}}{(\mu + 1)! \cdot 2^{\mu n}}.$$
 (35)

It is likely to have  $C \ll u$  and m relatively small in practice. Therefore, the 1st terms in Eqs. (34) and (35) likely dominates, and it is likely to have

$$\frac{2\mu(q_{\mathcal{A}}+q_{\mathcal{D}}+u\cdot m)(C+1)}{2^{k}} \ll \frac{2\mu \cdot u(q_{\mathcal{A}}+q_{\mathcal{D}}+m)}{2^{k}}$$

i.e., our dedicated bound Eq. (34) is slightly better than the naïve one.

*Proof* We start by sketching the simulator S. For each index  $idx \in \{1, ..., u\}$ ,  $\mathcal{S}$  distinguishes two cases as follows.

Case 1: player  $\mathsf{P}_{\mathsf{A},\mathsf{idx}}$  is corrupted. Thus, the adversary  $\mathcal{A}$  controls  $\mathsf{P}_{\mathsf{A},\mathsf{idx}}$  as well as the adversarial interface of  $\mathcal{F}_{\Delta-\mathsf{ROT}}(m,k)$ . In the case, the proof is fairly straightforward. Specifically,  $\mathcal{S}$  emulates functionality  $\mathcal{F}_{\Delta-\mathsf{ROT}}(m,k)$  by receiving  $\Delta$  and  $(\mathbf{a}_1,\ldots,\mathbf{a}_m)$  from  $\mathcal{A}$ . Then,  $\mathcal{S}$  (on behalf of  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ ) receives  $(IV, \mathbf{c}_1^0, \mathbf{c}_1^1, ..., \mathbf{c}_m^0, \mathbf{c}_m^0)$  from  $\mathcal{A}$ , and extracts the messages as follows:

$$\mathbf{m}_{i}^{0} := H(\mathbf{a}_{i}, IV \oplus [i]_{n}) \oplus \mathbf{c}_{i}^{0},$$
  
$$\mathbf{m}_{i}^{1} := H(\mathbf{a}_{i} \oplus \Delta, IV \oplus [i]_{n}) \oplus \mathbf{c}_{i}^{1}$$
(36)

for each  $i \in \{1, ..., m\}$ . Finally, S sends  $\{(\mathbf{m}_i^0, \mathbf{m}_i^1)\}_{i=1}^m$  to functionality  $\mathcal{F}_{\mathsf{S}-\mathsf{OT}}(m, n)$  as the OT messages of sender  $\mathsf{P}_{\mathsf{A},\mathsf{idx}}$ .

Case 2: player  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$  is corrupted. Thus, the adversary  $\mathcal{A}$  controls  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$  as well as the adversarial interface of  $\mathcal{F}_{\mathsf{\Delta}-\mathsf{ROT}}(m,k)$ , and  $\mathcal{S}$  is responsible to simulate the  $\mathcal{F}_{\mathsf{\Delta}-\mathsf{ROT}}(m,k)$  functionality. It proceeds as follows:

- The simulator S initially chooses  $\Delta_{\mathsf{idx}} \stackrel{\$}{\leftarrow} \{0,1\}^k$  and  $IV_{\mathsf{idx}} \stackrel{\$}{\leftarrow} \{0,1,...,2^n 1\}$ , and takes an input  $P_{\mathsf{idx}} : \{0,1\}^k \to \{0,1\}$  at  $\mathcal{A}$ 's interface for  $\mathcal{F}_{\mathsf{\Delta}-\mathsf{ROT}}(m,k)$ , and returns  $P_{\mathsf{idx}}(\Delta_{\mathsf{idx}})$  to  $\mathcal{A}$  at the same interface. Further, if  $P_{\mathsf{idx}}(\Delta_{\mathsf{idx}}) = 0$ , S stops accepting any further messages from  $\mathsf{P}_{\mathsf{A},\mathsf{idx}}$  or  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ . (Thus, in the following, we assume  $P_{\mathsf{idx}}(\Delta_{\mathsf{idx}}) = 1$ .)
- Upon receiving  $(x_{idx,1}, \ldots, x_{idx,m})$  at  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ 's interface for  $\mathcal{F}_{\Delta-\mathsf{ROT}}(m,k)$ , and  $\mathbf{z}_{\mathsf{idx},1}, \ldots, \mathbf{z}_{\mathsf{idx},m}$  at  $\mathcal{A}$ 's interface, the simulator  $\mathcal{S}$  inputs  $(x_{\mathsf{idx},1}, \ldots, x_{\mathsf{idx},m})$  to  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ 's interface of  $\mathcal{F}_{\mathsf{S}-\mathsf{OT}}(m,k)$ , and obtains  $\mathbf{m}_{\mathsf{idx},1}^{x_1}, \ldots, \mathbf{m}_{\mathsf{idx},m}^{x_m}$  back.
- The simulator S outputs  $(\mathbf{z}_{\mathsf{idx},1},\ldots,\mathbf{z}_{\mathsf{idx},m})$  at  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ 's interface of  $\mathcal{F}_{\Delta-\mathsf{ROT}}(m,k)$ .

- Finally, S sets

$$\mathbf{c}_{\mathsf{idx},i}^{x_i} \leftarrow H\left(\mathbf{z}_{\mathsf{idx},i}, IV_{\mathsf{idx}} \oplus [i]_n\right) \oplus \mathbf{m}_{\mathsf{idx},i}^{x_{\mathsf{idx},i}}, \quad \mathbf{c}_{\mathsf{idx},i}^{1-x_{\mathsf{idx},i}} \stackrel{\$}{\leftarrow} \{0,1\}^n$$

for all  $i \in \{1, ..., m\}$ . It then outputs  $IV_{\mathsf{idx}}, \mathbf{c}^0_{\mathsf{idx},1}, \mathbf{c}^1_{\mathsf{idx},1}, \ldots, \mathbf{c}^0_{\mathsf{idx},m}, \mathbf{c}^1_{\mathsf{idx},m}$  as the protocol message sent to  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ .

Reduction to muTCCRL security. Now, we proceed to define the adversary  $\mathcal{B}$  against muTCCRL security of H. In our setting,  $\mathcal{B}$  has access to a pair of oracles  $(\mathcal{O}, \mathcal{L}_{\Delta})$  (for  $\Delta = (\Delta_1, ..., \Delta_u) \stackrel{\$}{\leftarrow} (\{0, 1\}^k)^u$ ), where  $\mathcal{O}$  implements either  $\mathcal{O}_{\Delta}^{\text{muTCCRL}}$  or f. Due to the presence of the key leaking oracle, the construction of  $\mathcal{B}$  is simpler than previous works [12,7]. In detail, for each idx  $\in \{1, ..., u\}, \mathcal{B}$  simulates the above ideal world execution as follows:

- 1. If player  $P_{A,idx}$  is corrupted then  $\mathcal{B}$  simulates the protocol execution by extracting the OT messages as described above. Else, i.e., player  $P_{B,idx}$  is corrupted,  $\mathcal{B}$  proceeds to step 2.
- 2.  $\mathcal{B}$  initially takes an input  $P_{\mathsf{idx}} : \{0,1\}^k \to \{0,1\}$  at  $\mathcal{A}$ 's interface for  $\mathcal{F}_{\Delta-\mathsf{ROT}}(m,k)$ . It queries  $\mathcal{L}_{\Delta}(\mathsf{idx}, P_{\mathsf{idx}}) \to r$ , returns 1 to  $\mathcal{A}$  if r = 1, and stops accepting any further messages if  $\mathcal{L}_{\Delta}(\mathsf{idx}, P_{\mathsf{idx}})$  aborts.
- 3. Upon receiving  $(x_{\mathsf{idx},1},\ldots,x_{\mathsf{idx},m})$  at  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ 's interface for  $\mathcal{F}_{\Delta-\mathsf{ROT}}(m,k)$ , and  $\mathbf{z}_{\mathsf{idx},1},\ldots,\mathbf{z}_{\mathsf{idx},m}$  at  $\mathcal{A}$ 's interface,  $\mathcal{B}$  inputs  $(x_{\mathsf{idx},1},\ldots,x_{\mathsf{idx},m})$  to  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ 's interface of  $\mathcal{F}_{\mathsf{S-OT}}(m,k)$ , and obtains  $\mathbf{m}_{\mathsf{idx},1}^{x_{\mathsf{idx},1}},\ldots,\mathbf{m}_{\mathsf{idx},m}^{x_{\mathsf{idx},m}}$  back.

4.  $\mathcal{B}$  outputs  $(\mathbf{z}_{\mathsf{idx},1},\ldots,\mathbf{z}_{\mathsf{idx},m})$  at  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ 's interface of  $\mathcal{F}_{\Delta-\mathsf{ROT}}(m,k)$ .

5. Finally,  $\mathcal{S}$  sets

$$\begin{split} \mathbf{c}_{\mathsf{idx},i}^{x_{\mathsf{idx},i}} &\leftarrow H\left(\mathbf{z}_{\mathsf{idx},i}, IV_{\mathsf{idx}} \oplus [i]_n\right) \oplus \mathbf{m}_{\mathsf{idx},i}^{x_{\mathsf{idx},i}}, \\ \mathbf{c}_{\mathsf{idx},i}^{1-x_{\mathsf{idx},i}} &\leftarrow \mathcal{O}\left(\mathbf{z}_{\mathsf{idx},i}, IV_{\mathsf{idx}} \oplus [i]_n\right) \oplus \mathbf{m}_{\mathsf{idx},i}^{x_{\mathsf{idx},i}}. \end{split}$$

for all  $i \in \{1, ..., m\}$ . It then outputs  $IV_{\mathsf{idx}}, \mathbf{c}^0_{\mathsf{idx},1}, \mathbf{c}^1_{\mathsf{idx},1}, \ldots, \mathbf{c}^0_{\mathsf{idx},m}, \mathbf{c}^1_{\mathsf{idx},m}$  as the protocol message sent to  $\mathsf{P}_{\mathsf{B},\mathsf{idx}}$ .

 $\mathcal{B}$  finally outputs  $\mathcal{D}$ 's decision bit. It is easy to see: when  $\mathcal{O}$  implements  $\mathcal{O}^{\text{muTCCRL}}_{\Delta}$ ,  $\mathcal{B}$  simulates the real world execution; when  $\mathcal{O}$  implements f,  $\mathcal{B}$  simulates the ideal world execution. Therefore,

$$\mathbf{Adv}_{\Pi_{\mathrm{OT}}^{m,k,n},\mathsf{Corr},u}^{(\mathcal{F}\to\mathcal{G})-\mathrm{mu-mpc}}(\mathcal{A},\mathcal{D},\mathcal{S},X) \leq \mathbf{Adv}_{H,\{0,1\}^k,\mathcal{P}_{\mathsf{free}},u,\mu}^{\mathrm{muTCCRL}}(\mathcal{B}).$$
(37)

When H is  $\widehat{\mathsf{MMO}}^E$ , for any threshold  $\mu$  we further have

$$\begin{split} \mathbf{Adv}_{\Pi_{\mathrm{OT}}^{m,k,n},\mathsf{Corr},u}^{(\mathcal{F}\to\mathcal{G})-\mathrm{nu-mpc}}(\mathcal{A},\mathcal{D},\mathcal{S},X) &\leq \frac{2\mu(q_{\mathcal{A}}+q_{\mathcal{D}}+u\cdot m)(C+1)}{2^{k}} \\ &+ \frac{(\mu-1)\cdot u\cdot m(C+1)}{2^{k}} + \frac{(u\cdot m)^{\mu+1}}{(\mu+1)!\cdot 2^{\mu n}}. \end{split}$$

by Theorem 1 and Lemma 1. This completes the proof.

#### 6 Conclusion

Many OT extension schemes are built upon tweakable circular correlation robust (TCCR) hash functions, and allow the adversary to extract key information via a key leaking query. With this in mind, we incorporate key leaking query mechanism into the security definition of [11] and propose a notion named *multi-user tweakable circular correlation robustness with key leakages.* We then exhibit both security proofs and matching attacks w.r.t. the blockcipher-based TCCR hash of [11]. This enables constructing an OT extension protocol with non-trivial multi-user security. Our results may provide useful building blocks to the NIST standardization process of multi-party threshold cryptographic schemes [19].

#### A Proof of Lemma 1

Consider the *i*th sequence of balls. As per our assumption, these  $q_i$  balls are thrown into the bins of indices  $\gamma(1) \oplus IV_i, \gamma(2) \oplus IV_i, ..., \gamma(q_i) \oplus IV_i$  with  $IV_i \stackrel{\$}{\leftarrow} \{0, 1\}^n$ . Since  $\gamma$  is bijective, the  $q_i$  indices are pairwise distinct. Therefore, for a certain bin, the probability that it gets a ball after the *i*th experiment is  $q_i/2^n$ .

Now, consider some  $\mu$  sequences of balls, i.e., the  $i_1$ th, ...,  $i_{\mu}$ th, and consider the event that there is a  $a \in \{0, 1\}^n$  such that every one of those sequences hits the *a*th bin. By the above, the probability is

$$2^n \times \frac{q_{i_1}}{2^n} \times \cdots \times \frac{q_{i_{\mu}}}{2^n} = \frac{q_{i_1} \times \cdots \times q_{i_{\mu}}}{2^{n \cdot (\mu - 1)}}.$$

Since  $\mu^*$  is the maximum number of balls in any of the  $2^n$  bins, we have

$$\Pr[\mu^* \ge \mu] \le \sum_{0 < i_1 < i_2 < \dots < i_\mu \le u} \frac{q_{i_1} \times \dots \times q_{i_\mu}}{2^{n \cdot (\mu - 1)}}$$

Observing that

$$(q_1 + q_2 + \dots + q_u)^{\mu} \ge \sum_{i_1 \neq i_2 \neq \dots \neq i_{\mu}} q_{i_1} \times \dots \times q_{i_{\mu}}$$
$$= \mu! \cdot \sum_{i_1 < i_2 < \dots < i_{\mu}} q_{i_1} \times \dots \times q_{i_{\mu}},$$

we have

$$\sum_{i_1 < i_2 < \dots < i_{\mu}} q_{i_1} \times \dots \times q_{i_{\mu}} \le \frac{(q_1 + q_2 + \dots + q_u)^{\mu}}{\mu!}.$$

Therefore,

$$\Pr[\mu^* > \mu] = \Pr[\mu^* \ge \mu + 1] \le \frac{1}{2^{n \cdot \mu}} \times \frac{(q_1 + \dots + q_u)^{\mu + 1}}{(\mu + 1)!} = \frac{q^{\mu + 1}}{(\mu + 1)! \cdot 2^{n \cdot \mu}}$$

This complete the proof.
